Keywords: Airborne MIMO radar; Clutter modeling; Error conditions; Clutter characteristics

Abstract: For the issue of MIMO airborne radar clutter modeling in different environment conditions, a clutter modeling method based on composite model is proposed. It builds different types of clutter model through the changes of model parameters. The clutter model consists of clutter amplitude distribution model, and clutter cell scattering model. After considering the error factors such as element error, channel error, clutter fluctuation, a clutter modeling method based on composite model under error conditions is proposed. Finally, the computer simulation is made about the amplitude, the back-scatter coefficient, error factors, the space-time MV spectrum and the characteristic spectrum of different types of clutter through changing the model parameters. The simulation results show that: In ideal conditions, the Clutter Spectrum has good space-time characteristic, but in error conditions, the clutter fluctuates tempestuously, and in different environment conditions the fluctuation degree is different.

Introduction

How to suppress the strong ground clutter and other interference while the airborne radar is detecting moving target is the main problem now. Therefore，clutter modeling and simulation technology is always one of the research hotpots of radar application. The clutter modeling and simulation technology is always one of the research hotspots of radar application. Through deep research of clutter characteristic, the scholars obtained significative achievements. In [1-3],according to the radar resolution ratio and the amplitude modeling under different conditions, the Rayleigh model, Log-Normal model and Weibull model are proposed, they can match the amplitude data of the clutter properly. However, there are few research in the clutter modeling of MIMO radar, in[5]and [6],a clutter modeling method of airbore MIMO radar is proposed, but the element error, channel error and the gesture variation of the plane are not taken into account. In[7]a clutter model of airborne MIMO radar is established，but in this model ,the clutter has no fluctuation, non-Gaussian process is not under consideration.

Aiming at the limitation of the clutter model all above, this paper combines the common clutter amplitude distribution model, clutter cell scattering model and the radar parameter model ,considering the effect of element error, channel error and clutter fluctuation as well, a clutter modeling method based on composite model under error conditions is proposed .The model can reflect the generating principium and the statistical characteristic of clutter, in addition, it adapts to different environment and different error conditions.

The geometrical model of airborne MIMO radar

Fig.1 illustrates the geometrical model of Side-Looking airborne MIMO radar array antenna .The radar platform travels at velocity v in the positive direction of x axis, the altitude of the array phase center is H. The azimuth angle of the clutter scattering cell is θ,the elevation angle is φ,and the cone angle is ψ.We assume that during the Coherent Processing Intervals(CPI),the plane moving range is much more smaller than the slant range between the radar and the clutter source. Suppose that the antenna array has a side-looking uniform linear arrays configuration with M transmitting antenna elements and N receiving antenna elements. Let d_T be the space of each two adjacent

transmitting antenna elements while d_R be the space of each two adjacent receiving antenna elements. The ratio of space between each two transmitting and receiving elements is $\alpha = d_T / d_R$ .Let K be the number of radar pulses in one coherent processing interval (CPI).

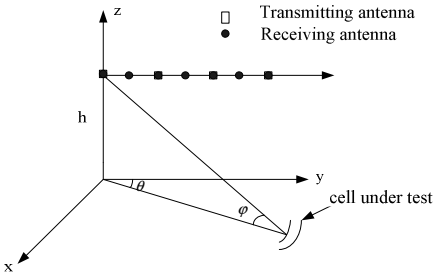

Fig.1 The model of airborne MIMO radar system

The amplitude distribution model of clutter

One of the nonhomogeneous performances of clutter is the clutter amplitude fluctuation. This fluctuation is stochastic, but taking one with another, such as Log-normal distribution：

$$p(X) = \frac{1}{2\pi\sigma X}\exp(-\frac{[\ln(X / X_m)]^2}{2\sigma^2}), (X \geq 0) \tag{1}$$

X_m is the median of X , σ is the standard deviation.

Another matching approximate distribution is Weibull distribution：

$$p(X) = \alpha\lambda X^{\alpha-1}\exp(-X^{\alpha}), (X \geq 0) \tag{2}$$

Here, α and λ are both constant, α is the parameter related to the distribution slope of Weibull., λ is called the Weibull parameter.

The scattering model of clutter cell

The radar cross section(RCS)is decided by the scattering model of the clutter cell, it can be defined as follow:

$$\sigma_c(R_S) = A_b \times \sigma_0(R_S) \tag{3}$$

A_b is the projection area of the clutter cell in the line of sight of radar, $\sigma_0(R_S)$ is the reflectivity . The strong and weak of radar clutter is always described by the reflectivity. A common reflectivity model is Morchin model0,which is given by:

$$\sigma_0(r) = \frac{A\sigma^0 \sin\theta_g}{\lambda} + \mu(ctg\beta_0)^2 \exp[\frac{tg(\beta_0 - \theta_g)^2}{tg\beta_0^2}] \tag{4}$$

λ is the wavelength of radar，θg is the grazing angle, A , B , β_0 , σ_m^0 , μ are the model parameter, Table 1 shows the typical simulation parameter of ground clutter.

$$\mu = \sqrt{f_0(GHz)} / 4.7 \tag{5}$$

f_0 is the frequency of radar.

Table 1 A set of typical ground clutters simulation parameter

	A	B	β_0	σ^0
desert	0.00126	$\pi/2$	0.14	F
farmland	0.004	$\pi/2$	0.2	1
hill	0.0126	$\pi/2$	0.4	1
mountain	0.04	$\pi/2$	0.5	1

$$\mathrm{F}=\begin{cases}\left(\dfrac{\theta_g}{\theta_c}\right)^k & \theta_g<\theta_c \\ 1 & \theta_g>\theta_c\end{cases} \tag{6}$$

θ_g is the grazing angle θ_c is the Transitional angle[11].

The composite model of airborne MIMO radar

The clutter signal of the i th gridding in the l th range ring can be denoted with the description of the amplitude distribution model of clutter, the scattering model of clutter cell and the radar parameter model:

$$\mathbf{c}_l(m,n,k)=\sum_{i=1}^{N_\theta}\frac{\sqrt{G}}{R_l^2}a_{il}e^{j\Phi}e^{j\alpha(m-1)\omega_s+j(n-1)\omega_s+j(k-1)\omega_t} \tag{10}$$

$m=1,2,\cdots,M$, $n=1,2,\cdots,N$, $k=1,2,\cdots,K$, M， Nand K are the amount of transmitting antenna ,receiving antenna and pulse respectively. R_l is the range between the l th range ring and the clutter cell. Φ is the random phase item， a_{il} is the sequence of clutter amplitude fluctuation. $\omega_s=(2\pi d/\lambda)\cos\theta_{li}\cos\phi_l$ and $\omega_t=2\pi f_{dl}/f_r$ are the airspace angular frequency and the time domain angular frequency respectively , d is the space of each two antenna， f_{dl} is the Doppler frequency of the l th range ring, f_r is the PRF. G is given by:

$$G=\frac{D_u P_t G_{t0} G_{r0}\lambda^2}{(4\pi)^3\Gamma}\sigma_c(r) \tag{11}$$

P_t is the radar pulsed power, $D_u=D\tau/T_r$ is the duty ratio, G_{t0} and G_{r0} are the power gain of the transmitting antenna and receiving respectively. Γ is the loss factor of the system, $\sigma_c(r)$ is denoted in formular(3).

Then element error of the transmitting antenna and receiving antenna is given by:

$$\rho_{p_1p_2}^{(\text{cell})}=\left(1+ea_{p_1p_2}\right)\exp\left(\mathrm{j}ep_{p_1p_2}\right) \tag{12}$$

$ea_{p_1p_2}$ ， $ep_{p_1p_2}$ is the element error， when $p_{1\neq}p_2, ea_{p_1p_2}=ep_{p_1p_2}=0$ 。

The channel error is given by:

$$\rho_{p_1p_2}^{(\text{channel})}=\left(1+ca_{p_1p_2}\right)\exp\left(\mathrm{j}cp_{p_1p_2}\right) \tag{13}$$

$p_1,p_2=n+(m-1)M,\ n=1,...,N,m=1,...,M$ $ea_{p_1p_2}$, $ep_{p_1p_2}$ denote the channel error between the p_1 th channel and the p_2 th channel .

The clutter fluctuation always obey the Gaussian distribution ,it can be expressed in:

$$\rho_{k_1k_2}^{(c)}=\exp\left(-B_c^2\left(k_1-k_2\right)^2/8\right) \tag{14}$$

$k_1=1,2,...,K,k_2=1,2,...,K$ 。

The clutter model can be expressed as follow after considering all kinds of the errors above:

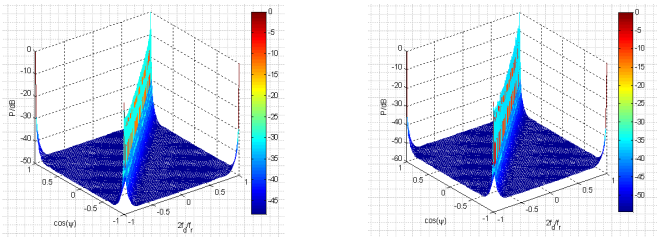
$$r_l(\Delta m,\Delta n,\Delta k)=\sum_{i=1}^{N_\theta}\sum_{i=1}^{N_\theta}\exp\left(-B_c^2(\Delta k)^2/8\right)\left(1+ca_{p_1p_2}\right)\exp\left(jcp_{p_1p_2}\right) \tag{15}$$
$$\frac{\left(1+ea_{p_1p_2}\right)\exp\left(jep_{p_1p_2}\right)G}{R_l^4}a_{il}e^{j\Phi}e^{j\alpha\Delta m\omega_s+j\Delta n\omega_s+j\Delta k\omega_t}$$

Simulation results

In order to analyze the clutter distribution of airborne MIMO radar, a plenty of simulation has been processed. The parameter of the model are: the amount of transmitting antenna M= 8，the amount of

receiving antenna N= 8，the amount of pulses K= 16,the wavelength $\lambda = 0.23m$，the space of each two adjacent receiving antenna elements $d_R = \lambda / 2$, the ratio of space between each two transmitting and receiving elements is $\gamma = 10$，the velocity of the platform V= 140 km/h，the hight of the platform H=8 km，the PDF is f=2438. 8Hz，the transmitting power P= 180kW，the clutter-noise ratio $R_{CN} = 60dB$.Experiment 1: the clutter spectrum in different environment under ideal conditions

The simulation is implemented in two typical environments: desert and mountain. The clutter amplitude distribution obeys Log-normal distribution, while the clutter scaterring cell parameter refers to Table 1.

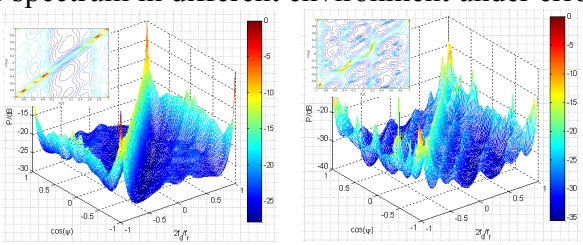


(a) The ground clutter in desert (b) The ground clutter in mountains

Fig. 2 The space-time MV spectrum plot of airborne MIMO radar under ideal conditions

Fig.2 shows that the clutter distribution has diagonal characteristic. By comparing Fig.2 with Fig.3, we can see that in desert environment, the fluctuation of the clutter spectrum is flatter, while in mountain environment, the fluctuation is more tempestuously.

Experiment 2: the clutter spectrum in different environment under error conditions



(a) The ground clutter in desert (b) The ground clutter in mountains

Fig.6 The space-time MV spectrum and contour plot of airborne MIMO radar under different kinds of errors.

Fig.3 shows that element error causes the clutter spectrum fluctuated tempestuously. Fig.4 shows that channel error causes the clutter spectrum extension and clutter fluctuation. Fig.5 shows that the main effect caused by clutter fluctuation is spectrum extension. Fig.6 shows that the space-time coupling characteristic is not obvious under different kinds of errors.

Conclusions

Aiming at clutter modeling of airborne MIMO radar in different geomorphic feature and different error conditions, a clutter modeling method based on composite model under error conditions is proposed .The simulation results show that the clutter spectrum of the airborne MIMO radar has good space-time two-dimensional characteristics and the element error, channel error, clutter fluctuation. etc make the spectrum wider, increase the degree of freedom of clutter as well, among all the errors, the element error has the strongest effect.

Keywords: genetic algorithms; BP neural network; oriented identification

Abstract. The genetic algorithm is a randomized search method for a class of reference biological evolution of the law evolved, with global implicit parallelism inherent and better optimization. This paper presents an adaptive genetic algorithm to optimize the use of BP neural network method, namely the structure of weights and thresholds to optimize BP neural network to achieve the recognition of banknotes oriented. Experimental results show that after using genetic algorithms to optimize BP neural network controller can accurately and quickly achieved recognition effect on banknote recognition accuracy compared to traditional BP neural network has been greatly improved, improved network adaptive capacity and generalization ability.

Introduction

In recent years, paper currency image recognition technology is a more active issue in the field of pattern recognition, relying on image recognition banknote sorter at the core of the bill is playing an increasingly important role. Banknote sorter is a mechatronics financial instruments, has great market potential, and its main function is to identify the nominal value and for banknotes. For identifying the bill generally preclude the use of the current gradation weighting method accurate and convenient to implement. In addition, BP neural network has been facing in achieving recognition in the widely used, but due to the traditional BP neural network recognition of banknotes, while having good generalization ability, but the recognition rate is not very high[1]. Based on the banknote image recognition technology in-depth study and research, this paper proposes a genetic algorithm to optimize BP neural network to recognize banknotes oriented, the BP network weights and thresholds to optimize this method with the traditional BP neural network algorithm has improved significantly compared to the recognition accuracy.

1 Materials and Methods

1.1 Banknote image pre-processing and feature extraction

After this paper CCD image acquisition devices to get 100 RMB banknote images, we must first go through a series of image pre-processing, including image de-noising, image edge positioning, and tilt correction processing to ensure the accuracy of feature extraction. After the feature extraction, and then into the neural network.

In this paper, the method of adaptive median filter will be used to de-noise the 100 RMB banknote image, to give the image shown in the following Figure1. (a:the collected banknote image b:graphic containing salt and pepper noise c: median filtered image)

（a）Banknote image acquisition

Fig.1 Median filtered banknote image

The bill will go through de-noising images obtained, and then locate the edge of the work, mainly in the edge of goals and objectives between the target and the background, region to region. In this paper, the canny edge detection[2], shown in Figure 2.

Fig.2 Edge positioning image

In the banknote image acquisition process, there will be more or less inclined to some extent, it has a great impact on the banknote image for a correct recognition, and therefore, it is necessary to adjust the inclination of the banknote and the corrected image[3]. By the edge detection, and then use the Hough transform to detect we get four straight edges of the banknote, and the rotation correction in accordance with the bilinear interpolation and the horizontal angle between the straight line. Corrected image shown in Figure 3.

Fig.3 Tilt correction image

After a series of pre-processing, we can get the effective area of the image after the correction bill. Then you can banknote image feature extraction. The ranks of the image according to a certain number of segmentation, get a matrix-type sub-region, we can characterize an original feature in the promoter region of gray value[4]. The division method of the grid still does not have a theoretical guidance, is that we need to solve the problem. This paper uses a distance separability criterion to take all the appropriate size and number grid. To acquire a 100 RMB note positive positive image, for example, to take a fixed area renminbi center mesh partition, as shown in Figure 4. Now the central region 128 is divided into a rectangular region, this includes not only the banknote segmentation method substantially valid image information and image texture features, and in addition to containing a sawtooth edge noise and improve the accuracy of recognition.

Fig.4 Split feature block diagram

1.2 AGA-BP Network

Genetic algorithm GA (Genetic Algorithm) is based on Darwin's theory of evolution, a simulation of biological evolution mechanism robust optimization algorithm. Genetic algorithm based on sample questions for initial population fitness function selection, crossover and mutation, to guide learning and determine the search direction[5]. Simple genetic algorithm is a stochastic search algorithm probability evolution, it has a very good global search capability, but poor performance in terms of local search. In this paper, modified by genetic algorithm crossover and mutation probability, called adaptive genetic algorithm (AGA algorithm for short), the choice of an adaptive change important parameters rather than fixed to interact with the fitness function autoregulation. When an individual or similarity of the population tends to increase local minimal, crossover probability and mutation probability increases. When the population of individual fitness value is large, and the similarity of the population is low, the crossover probability and mutation probability decreases. Which not only improves search efficiency of genetic algorithms, but also effectively avoid local minimum. Crossover probability and mutation probability to make the following adjustments:

$$P_c = \begin{cases} P_{c1} - \dfrac{(P_{c1} - P_{c2})(f' - f_{\max})}{f_{\max} - f_{avg}} & f \geq f_{avg} \\ P_{c2} & f < f_{avg} \end{cases}$$

$$P_m = \begin{cases} P_{m1} - \dfrac{(P_{m1} - P_{m2})(f_{\max} - f'')}{f_{\max} - f_{avg}} & f \geq f_{avg} \\ P_{m2} & f < f_{avg} \end{cases} \qquad (1)$$

$f_{\max}$ the maximum fitness value; f_{avg} average fitness value; f' the larger of the two individual cross adaptation value, f'' for the variability of individual fitness value,In the above formula P_{c1} , P_{c2} , P_{m1} , P_{m2} Desirable value $P_{c1} = 0.9$, $P_{c2} = 0.6$, $P_{m1} = 0.1$, $P_{m2} = 0.0001$ .By AGA optimization algorithm to determine the weights and thresholds used in the initial space defined by the BP neural network for gene selection, crossover and mutation, and then the sample individual merit continued evolution, and ultimately chose the fitness of individuals to determine the maximum network structure, weights and thresholds.AGA-BP algorithm flow shown in Figure 5:

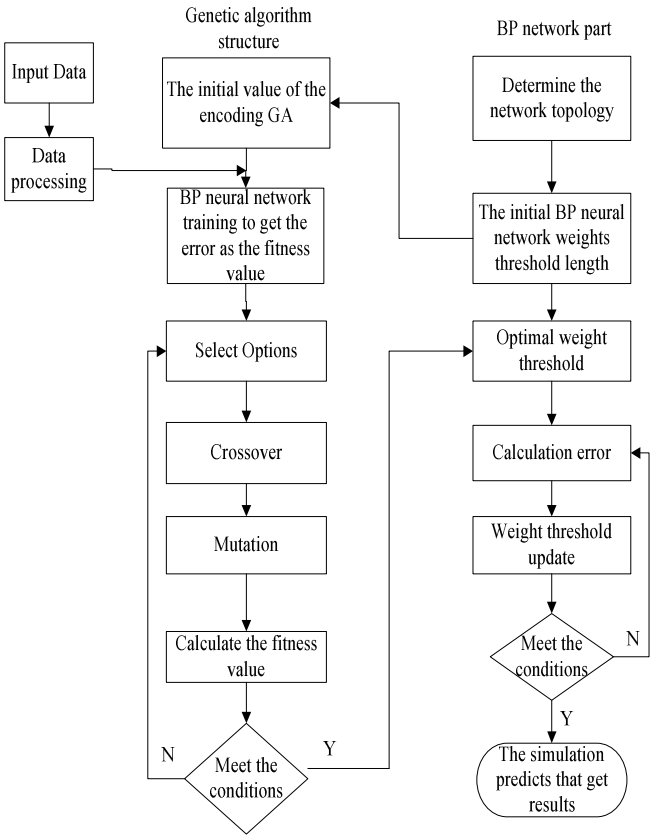

Fig.5 AGA-BP optimization algorithm flowchart

Firstly, the use of adaptive genetic algorithm to get the initial weights and structure of BP network, and then BP network training, choice of fitness as the biggest problem solution based on the results obtained in the final solution. Specific steps are as follows:

1) the use of three BP network , determine the number of nodes in the input layer BP network problems to be solved according to the number of output layer nodes. 2) real number encoding, in the basic solution space randomly generated set of neural networks have a real type of weight distribution, the value will cascade into the ownership of a long string in a certain order , each string is an individual, a group corresponding network weights and thresholds. 3) obtained by decoding the corresponding network weights and thresholds. 4) BP network samples were normalized , the right to use the threshold value obtained by decoding BP network training to get the output value is calculated for each individual's fitness. 5) to determine whether the population size, if not the genetic manipulation. Select the operation using the optimal selection strategy to select individual fitness highest remaining individuals using roulette method determines whether to enter the next generation. 6) The selection, crossover and mutation of the individual merged to form a new generation of the population, and set evolution algebra by 1, repeat steps 3-6 until the evolution algebra. Calculate the new population fitness value of each individual, to get the highest individual fitness. 7) for the largest individual fitness decode parameter combinations at this time was already sufficiently close to the optimum value, on the basis of learning with BP algorithm, the optimal weights and thresholds of the network. 8) obtained with the optimum weights and thresholds to identify training.

2 Experiments and results analysis

Before the neural network training, we must first select the training samples, in the paper, 100 RMB as the research object, whichever is different for each of the four samples of 3000, each class in the training and testing samples mixed with some slight cracks and noise banknotes. Each class in 1000 as training samples, each image has 128 eigenvalues for training artificial networks, a total of 128,000 eigenvalues. The remaining 2000 sample image as a test network.

Genetic algorithm parameter settings: initial population size of 230, crossover probability is 0.7, mutation rate of 0.03; Neural network parameter settings: network model is used in the BP network, and each layer activation functions are S-type function, input neurons BP network is 128, hidden layer nodes is 30, the output neurons of 4. After the network design is completed, the sample can be trained. After all samples positive input, if there is greater than the need to reverse the expected error correction weights. In the training process, the sample will be used repeatedly, it is best to change the order of input sample data at every training. When training a certain number of network errors will tend to a stable value. After the network training is complete, save the weights of the network, then the network performance test samples for testing, the results in Table 1 below:

Table 1 The simulation test results to identify

100 RMB face	The number of training samples	The number of samples tested	Successful identification number	Recognition rate
Positive forward	1000	2000	1991	99.7%
Positive reverse	1000	2000	1989	99.5%
Negative forward	1000	2000	1993	99.8%
Negative reverse	1000	2000	1987	99.3%

Experimental results show that: the use of adaptive genetic algorithm to optimize the BP neural network, BP neural obtain optimal structure of the network weights and thresholds, increasing the overall search capability and convergence speed of the network. BP neural network with adaptive genetic algorithm can greatly enhance the speed of the network and allows network to avoid falling into local minimal and improve the adaptive ability and generalization ability of the network.

3 Conclusion

This article describes an AGA-BP neural network recognition algorithm for banknote, through experimental analysis of the performance of the algorithm. The test results show that the algorithm can significantly improve the recognition accuracy proved adaptive genetic algorithm to optimize the BP network for the recognition of the practical application of the bill is feasible.

Wavelet De-noising Algorithm Based on OpenCV for Images Edge Detection

Yifan Ma[1, a], Shugui Liu[2, b]

[1,2]State key laboratory of precision measuring technology and instrument, Tianjin University, Tianjin 300000, China.

[a]mayifan1990@163.com, [b]sgliu@163.com

Keywords: Wavelet, image de-noising, canny edge detection, OpenCV.

Abstract. Image edge detection is easily affected by noise. Wavelet algorithm can divide the image into low frequency and high frequency. By the processing of high frequency signal and the reconstruction of wavelet coefficients, the purpose of removing noise can be achieved. In the environment of VC++6.0, an image de-noising algorithm based on the wavelet combined with the Canny edge detection is proposed, which obtains a good result. The above algorithms are implemented based on OpenCV, which is more efficient, providing the conditions for subsequent image analysis and recognition. Experiments are carried out and the results show that the proposed algorithm is available and has a good performance.

Introduction

Image edge is considered as an important basis for image analysis and recognition. An image is often corrupted by noise in its acquisition and transmission. Image de-noising is used to remove the additive noise while retaining the important signal features as much as possible [1]. The traditional edge detection algorithms mainly function as high pass filter simply by convolution using differential operator in spatial domain. They are generally sensitive to noise without accurate identification. Canny edge detection algorithm based on optimization theory [2] has been widely applied with the advantages of high signal-to-noise ratio, high detection precision and small computation. Traditional canny edge detection is based on Gaussian filtering, which can suppress the Gaussian noise to a certain extent. However, when dealing with images with heavy noise in the actual engineering application, the degree of filtering is always proportional to the blur of image. Wavelet transform can reflect the local mutation signal sensitively with its time-frequency localization and multi-scale resolution [3]. By decomposing the image into low frequency and high frequency at multiple scales, noise signal in high frequency can be suppressed at an appropriate scale. Then de-noise image can be obtained from the reconstruction of low frequency signal and the treated high frequency signal.

OpenCV is an open source library widely used in image processing and computer vision. It can operate on image data conveniently with powerful image processing function. This paper completes the configuration of OpenCV in VC++6.0, develops wavelet de-noising procedure with the database of OpenCV, and then uses the Canny operator in OpenCV for image edge detection. The obtained edge is effective against noise with rich information.

Image De-noising Algorithm Based on Wavelet Analysis

Wavelet Theory. In Fourier transform, time domain signal is written as a superposition of a series of simple waves mathematically represented by sines and cosines to realize signal localization in the frequency domain. But it can't reflect the time-varying signal frequency. Wavelet transform is a convolution of the signal by a cluster of oscillation functions with different frequency [3]. The window function can be changed according to signal variations in size, forming a variable time-frequency window. For the high frequency information, time interval is smaller, which is rich in details; for the low frequency information, time interval becomes large, showing more complete information.

The wavelet transform is defined as:
L2(R) is vector space of measurable, square integrable function *f (x)*, for any *f(x) ∈ L2(R)*, the continuous wavelet transform is:

$$W_{a,b}(x)=\int_{-\infty}^{+\infty}\psi_{a,b}(x)f(x)dx=|a|^{-1/2}\int_{-\infty}^{+\infty}f(x)\psi(\frac{x-b}{a})dx \tag{1}$$

where $\psi(x)$ is wavelet function, a is scaling factor, b is shifting factor.
It corresponds to the decomposition of *f(x)*. It can be proved that the original signal *f(x)* can be restored from $W_{a,b}$, when the decomposition satisfies the following admissible condition [3]:

$$W_{\psi}=\int_{-\infty}^{+\infty}\frac{|\psi(\omega)|^2}{|\omega|}d\omega<\infty \tag{2}$$

Then, the inverse transform of wavelet, namely reconstruction formula is:

$$f(x)=\frac{1}{W_{\psi}}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}W_{a,b}(x)\psi_{a,b}(x)dadb \tag{3}$$

Let *a, b* in a discrete form:$a=a_0^m$, $b=nb_0a_0^m$; where $a_0>1, b_0\in R$, $m, n\in Z2$, we can get discrete wavelet transform. For most purposes, the wavelet model is not required to keep continuous scale. To allow fast numerical implementations, we impose that $a_0=2$, $b_0=1$ to get dyadic wavelet transform, which is extended to the two-dimensional form, used for wavelet decomposition and reconstruction of image.

The Principle of Wavelet De-noising. The useful signal is usually the low-frequency part and the noise is shown as the high-frequency signal. Wavelet de-noising can be attributed to a kind of low pass filtering in a certain extent. But wavelet de-noising can keep the original image characteristics while de-noising comparing with traditional low pass filter, without causing excessive fuzz.

Wavelet de-noising process can be represented by the following figure simply.

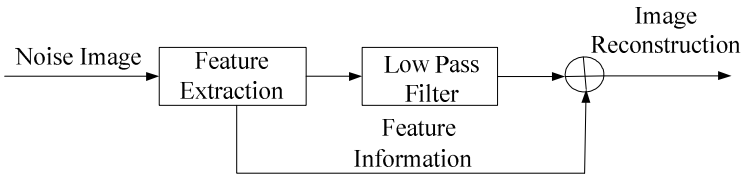

Fig. 2 Wavelet de-noising process

The first stage is the feature extraction. Select a suitable wavelet function to make wavelet transform of the image. The image is decomposed into low frequency and high frequency parts, as shown in the figure is one layer of decomposition and two layer of decomposition:

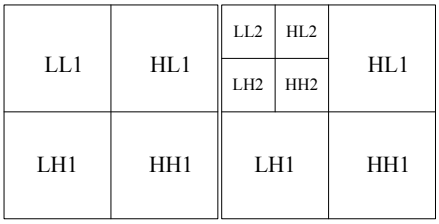

Fig. 3 One-layer and two-layer wavelet decomposition

One layer of decomposition divides the image into four parts, the low frequency image LL1, the high frequency detail image corresponding to the horizontal direction HL1, the vertical direction LH1, and the diagonal line direction HH1. Second layer decomposition only divides the low-frequency part of the upper layer, and so on. Feature extraction is to extract the high frequency part in an appropriate decomposition layer and direction according to the noise, to obtain the corresponding high-frequency coefficients.

The second stage is low pass filter. Select an appropriate threshold to quantify the extracted high frequency coefficients at each layer, and preserve the high frequency coefficients of suitable size, filter out the noise signal. The methods of threshold selection are usually hard thresholding and soft thresholding [5].

Hard thresholding formula:

$$W_{j,k} = \begin{cases} W_{j,k}, |W_{j,k}| \geq \lambda \\ 0, |W_{j,k}| < \lambda \end{cases} \quad (4)$$

Soft thresholding formula:

$$W_{j,k} = \begin{cases} sign(W_{j,k})(|W_{j,k}| - \lambda), |W_{j,k}| \geq \lambda \\ 0, |W_{j,k}| < \lambda \end{cases} \quad (5)$$

In the experiments, soft thresholding has been used over hard thresholding because it gives more visually pleasant images as compared to hard thresholding: reason being the latter is discontinuous and yields abrupt artifacts in the recovered images especially when the noise energy is significant.

The third stage is image reconstruction. Take the low frequency coefficients of the nth layer as the feature information and reconstruct the image together with the high frequency information at each layer after thresholding. Finally get the de-noise image.

Realization of Image Edge Detection Based on Wavelet De-noising

Algorithm Flow. The flow of this whole algorithm is as follows:

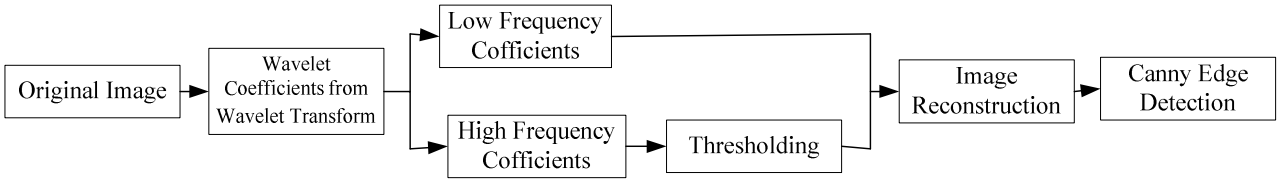

Fig. 4 Algorithm flow

OpenCV Implementation. OpenCV is an open source computer vision library written in C and C++. All images in OpenCV are operated in a same structure IplImage, which contains most of the required image information [6]. The main functions in program are:

Load an image: IplImage *cvLoadImage (const char *filename, int flags);

Allocate new image: IplImage *cvCreateImage (Cvsize size, int depth, int channels);

Define wavelet de-noising function: void cvWaveSmooth (const IplImage*src, IplImage*dst, int scale, int DecoWave, int RecoWave); DecoWave is decomposition wavelet, RecoWave is reconstruction wavelet.

Canny edge detection in OpenCV: Void cvCanny (const CvArr* image, CvArr* edge, double threshold1, double threshold2, int aperture_size=3);

Create a Window: int cvNamedWindow (const char *name, int flags);

Display an image: void cvShowImage (const char* name, const CvArr* image);

Wait and Clean: cvWaitKey (0); cvReleaseImage (&image); cvDestroyWindow ("source");

Experiment and Analysis of Results

In the OpenCV environment, extract the edge of the original image “lena.bmp” by cvCanny function. The two thresholds should be obtained according to the test. In this paper, threshold1=40, threshold2=100. The result is as figure 5.

Fig. 5 Left: original image. Right: Canny edge detection

Add a heavy Gaussian noise to the image, process the image by wavelet de-noising algorithm, then use the Canny algorithm for edge extraction. Contrast experiment: choose the traditional Gaussian filtering function for noise removal, and then Canny algorithm for edge extraction. The results are as follows:

Fig. 6 Left: noise image. Middle: Canny edge detection with Gaussian de-noising. Right: Canny edge detection with wavelet de-noising.

From the above experiments can be seen clearly, Canny algorithm can extract the coherent edge of the clear image with rich details in figure 5. But for the images with heavy noise, Gaussian filtering is difficult to ensure to suppress noise and preserve edge details in balance. Large threshold can remove noise, but obviously, lost a lot of details, and the edge is not consistent, as shown in the middle of figure 6. In contrast, combining wavelet de-noising with Canny edge detection can get the clear edge information, suppressing the impact on the edge detail information brought by noise well.

Summary

According to the characteristics of wavelet algorithm, the preprocessing of image with wavelet de-noising algorithm can largely eliminate noise effect in the latter part of Canny edge detection, which can obtain more rich real edge information. The algorithm is implemented in the OpenCV environment with its rich image processing library and the existing Canny algorithms. It makes a good foundation for further image analysis and recognition in the practical engineering with full use of the powerful vision library of OpenCV combined with wavelet algorithm.

Acknowledgment

We sincerely thank to the Natural Science Foundation of Tianjin for its financial support to the project. The granted project number is 13JCZDJC34500/E05020402.

Keywords: Antenna array, Fractional Fourier Transform (FRFT); Chirp Signal; Parameter Estimation

Abstract. This paper presents a multi-component chirp signal detection with new methods of parameter estimation. The method using spatial characteristics of the antenna array. By array average fractional Fourier domain weighting function is introduced to reduce noise and suppress mutual interference between the signals from different sources. And compared to a single array element method. The proposed method greatly improves the multi-component chirp signal detection and parameter estimation performance. Simulation results show the effectiveness of the method.

Introduction

Chirp class is one common signal signal signal processing field, whether in the nature of a natural signal, or artificially generated signals are abound. Therefore, the detection and parameter estimation of multicomponent chirp signal has been people's attention. In recent years, with the rapid development of the theory of fractional Fourier transform to produce a variety of multi-component chirp signal detection and parameter fractional Fourier transform-based estimation algorithm. This class method can effectively achieve the chirp signal while four parameter estimation, performance analysis and simulation results demonstrate the accuracy of detection and estimation results are better than the original class of time-frequency algorithms.

However, the existing research results of such algorithms is for both single sensor signal, and the antenna with the development of technology, the current radar, communications systems are used in many array antenna to improve system performance. Therefore, we studied the performance of detection and parameter estimation how to use the array signal processing techniques to improve existing algorithms.

2 Preliminaries

2.1 Signal Model

As used herein, the following model:

$$\mathbf{X}(t) = \mathbf{A}\mathbf{S}(t) + \mathbf{N}(t) \tag{1}$$

Where: $\mathbf{S}(t) = [s_1(t), s_2(t), ..., s_N(t)]^T$ is N dimensional vector consisting of N source signal; $\mathbf{X}(t) = [x_1(t), x_2(t), ..., x_M(t)]^T$ for the M dimensional observation data to Volume, whose elements are M output signal sensing unit; $M \times N (M \geq N)$ dimensional matrix $\mathbf{A} = [\mathbf{a_1}, \mathbf{a_2}, ..., \mathbf{a_N}]$ is called mixing matrix, Sok said its yuan mixed signal, the spatial characteristics of the column vector $\mathbf{a_i} = [a_{i1}, a_{i2}, ..., a_{iM}]^T$ represents the ith signal source; $\mathbf{N(t)} = [n_1(t), n_2(t), ..., n_M(t)]^T$ is an $M \times 1$ dimensional Noise vector.

Meaning of formula (1) is N source signal $\mathbf{S(t)}$ by the spatial characteristic is $\mathbf{A}$ M-dimensional array to obtain the observed data vector $\mathbf{X(t)}$. To simplify the discussion, assume that $\|\mathbf{a_i}\|^2 = M$, this assumption does not affect the results discussed below.

1.2 Chirp signal parameters estimation based on FRFT

Multi-component chirp signal using the following model, said:

$$x(t) = \sum_{i=1}^{N} \xi_i e^{j\varphi_i + j2\pi f_i t + j\pi\mu t^2}, \quad -\frac{\Delta t}{2} \leq t \leq \frac{\Delta t}{2} \tag{2}$$

Wherein: ξ_i is the amplitude; f_i is the center frequency; μ_i is the Chirp rate and φ_i is the initial phase.

Define the fractional Fourier transform can be found in the literature [1][2]. The use of fractional frequency distribution relationship with the Fourier transform, chirp can achieve signal detection and parameter estimation:

$$\{\hat{p}_i, \hat{u}_i\} = \arg\max_{p,u} \left| X_p(u) \right|^2 \tag{5}$$

$$\begin{cases} \hat{\mu}_i = -\cot(\hat{p}_i \pi / 2), \hat{\varphi}_i = \arg\left[\dfrac{X_{\hat{p}_i}(\hat{u}_i)}{A_{\hat{p}_i} e^{j\pi \hat{u}_i^2 \cot \hat{\alpha}_i}} \right] \\ \hat{f}_i = \hat{u}_i \csc(\hat{p}_i \pi / 2), \hat{\xi}_i = \dfrac{\left| X_{\hat{p}_i}(\hat{u}_0) \right|}{\Delta t \left| A_{\hat{p}_i} \right|} \end{cases} \tag{6}$$

The above method can be extended to multi-component chirp signal detection and parameter estimation, the difference between the multi-component signal strength is large, can be affected by one from strong to weak elimination method to suppress strong component when the component is weak. Provided that the strength of multi-component chirp signal a larger difference between weak and strong component interference component is very small, and can more accurately eliminate strong component in turn. However, in practical application of the above conditions is often difficult to ensure, particularly when the signal component is more, the strength of each component of the difference between minimal and similar parameter. (5) modulo operation will lead to interactions between the various components of the enhancement. At this mutual interference between multiple components will greatly reduce the detection and parameter estimation performance.

To solve this problem, we use an antenna array to suppress the effects of noise and interference items by FRFD array weighting, which effectively improve the performance of existing methods.

3 Weighted array FRFT

Noise can also be seen as a source of the signal we are not interested, that is, in (1) $\mathbf{X(t)}$ of formula can be seen as the product of the $N+1$ signal source by the mixing matrix $\mathbf{A}$. So from this point of the analysis of multi-component mutual interference between the signals departure (also as a source of the noise signal analysis), you can simplify the formu la (1) is expressed as:

$$\mathbf{X(t)} = \sum_{i=1}^{N} [\mathbf{a_i} \cdot \mathbf{s_i(t)}] \tag{7}$$

Formula (7) in order to simplify the expression put, the summation symbol represents N s uperscript still use. Then the output of the sensor k as:

$$x_k(t) = \sum_{i=1}^{N} [a_{ik} s_i(t)],\ k = 1, 2, ..., M \tag{8}$$

As the FRFT is a linear transformation. So for a single sensor output x_k are:

$$F_{x_k}(p,u) = \sum_{i=1}^{N} a_{ik} F_{s_j}(p,u) \tag{9}$$

Then

$$\left| F_{x_k}(p,u) \right|^2 = \sum_{i=1}^{N} \sum_{j=1}^{N} a_{ik} a_{jk}^* F_{s_i}(p,u) F_{s_j}^*(p,u) \tag{10}$$

After each antenna element can be obtained by averaging the output signal:

$$\overline{\left| F_{\mathbf{X}}(p,u) \right|^2} = \sum_{i=1}^{N} \sum_{j=1}^{N} \left(\frac{1}{M} \mathbf{a}_j^H \mathbf{a}_i \right) F_{s_i}(p,u) F_{sj}^*(p,u) \tag{11}$$

Wherein: $\mathbf{a}_j^H \mathbf{a}_i$ is the inner product of $\mathbf{a}_j$ and $\mathbf{a}_i$.

Easy to prove: vwhen $i = j$, $\mathbf{a}_j^H \mathbf{a}_i = \left\| \mathbf{a}_i \right\|^2 = M$; when $i \neq j$, $\mathbf{a}_j^H \mathbf{a}_i \leq M$.

Defining a variable $\lambda_{ij} = \frac{1}{M} a_j^H a_i$, thus, the formula (11) can be written as

$$\overline{\left|F_{\mathbf{X}}(p,u)\right|^2} = \sum_{i=1}^{N}\sum_{j=1}^{N} \lambda_{ij} F_{s_i}(p,u) F_{sj}^*(p,u) \tag{12}$$

Where

$$\begin{cases} \lambda_{ij} = 1, & i = j \\ \left|\lambda_{ij}\right| \le 1, & i \ne j \end{cases} \tag{13}$$

The equation above shows that Each element antenna array output signal averaged square modulus is a linear combination FRFT FRFT interference term between FRFT square modulus of each source signal and the different source signals.

May be a further written as:

$$\overline{\left|F_{\mathbf{X}}(p,u)\right|^2} = U^H \left[F_{\mathbf{s}} F_{\mathbf{s}}^*(p,u) .* \Phi \right] U \tag{14}$$

Where, "$.*$" means multiplying the corresponding element in the matrix; U is a unit vector of dimension $N \times 1$; $\mathbf{\Phi} = \mathbf{A}^H \mathbf{A} / M = \left[\lambda_{ij} \right]$, $i, j = 1, 2, ..., N$.

In matrix $F_{\mathbf{s}} F_{\mathbf{s}}^*(p,u) .* \Phi$, the diagonal elements represent the squared modulus FRFT each source signal is a non-diagonal elements and the j th FRFT source signals and source sign als i th multiplied by the conjugate, it is the interference term.

Each element of the matrix former also has a weighting coefficient λ_{ij}, when $i = j$, $\lambda_{ij} = 1$; the time when $i \ne j$, $\left|\lambda_{ij}\right| \le 1$.

That is, the matrix of diagonal elements of the weighting factors are 1, the non-diagonal elements of the weighting factor is less than 1. Thus, by means of the output signal of the antenna array will be able to average a good source of suppressing interference with other signals.

4 The theory of algorithm

According to the foregoing, you can get new detection and parameter estimation algorithm steps are:

Step 1: The first step to strike its FRFT square modulus of the input signal for each sensor unit;

Step 2:The second step, the result of each array element obtained by summing the first step, the average, and the noise is suppressed by the interference term average of the array;

Step 3: A third step according to equation (5), (6), in a plane of the square (p,u) modulus of the average value obtained FRFT the two stage two-dimensional search, obtained from the peak position $(\hat{p}_1, \hat{u}_1)$ of the strongest signal component $(i = 1)$ parameter estimates $\left\{ \hat{\xi}_1, \hat{\varphi}_1, \hat{f}_1, \hat{\mu}_1 \right\}$;

Step 4: The fourth step is the use of parameter estimates to recover the first signal component is:

$$\hat{s}_1(t) = \xi_1 e^{j2\pi f_1 t + j\pi\mu_1 t^2}, \quad -\frac{\Delta t}{2} \le t \le \frac{\Delta t}{2} \tag{15}$$

Step 5: to get a result $\hat{s}_1(t)$ in accordance with equation (15) FRFT square modulus $\left|F_{\hat{s}_1}(p,u)\right|^2$, and subtracted from $\overline{\left|F_{\mathbf{X}}(p,u)\right|^2}$, that is:

$$\overline{\left|F_{\mathbf{X}'}(p,u)\right|^2} = \overline{\left|F_{\mathbf{X}}(p,u)\right|^2} - \left|F_{\hat{s}_1}(p,u)\right|^2 \tag{16}$$

Step 6: the result will be the fifth step into the third step, repeat the above steps, followed by the rest of the signal components to get an estimate $\hat{s}_i(t)$, until the rest of the square modulus of the average peak FRFT no longer exceeds a predetermined threshold.

5 Simulation

The sampling frequency is herein Simulation 1000 Hz, the sampling points is 1000, the array element number were taken 1,2 and 8, two chirp signals are used as follows:

$$\begin{cases} s_1(t) = \xi_1 \cdot \exp(j2 + j\pi 4t + j\pi 5t^2) \\ s_2(t) = \xi_2 \cdot \exp(j\pi 8t + j\pi 3t^2) \end{cases} \tag{17}$$

The spatial direction of arrival is $\pi/8$ and $5\pi/12$ respectively.

We may assume that $s_1(t)$ is a useful signal, $s_2(t)$ is the interference signal, the dry signal ratio $ISR = 20\lg(\xi_2/\xi_1)$, range from -16dB to 0dB.

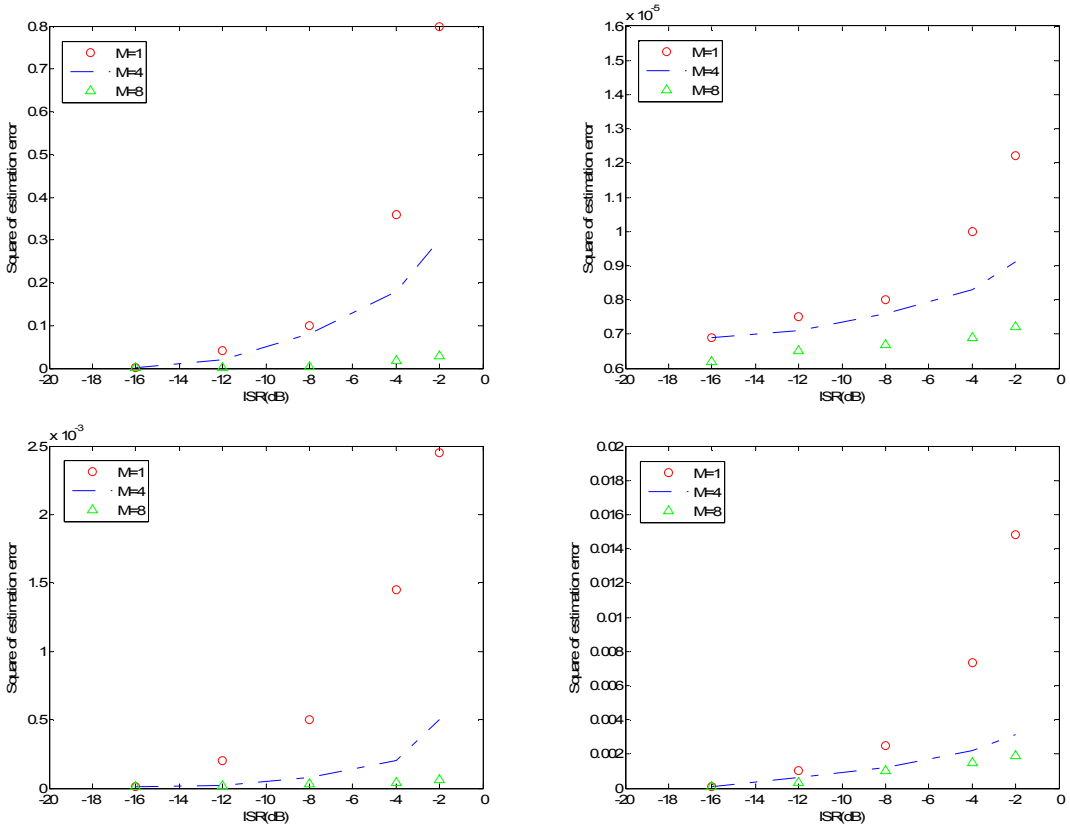

Fig3 The relationship with delay interval, code sequence and likelihood value

5 Summary

This paper proposes a multi-component chirp signal detection and parameter array FRFD new method based on the estimated weighted. Simulation results demonstrate the effectiveness and practicality of the method. And a single array element detection method, the new method can greatly improve the detection and parameter estimation performance, especially suitable for low signal to noise ratio, the number of components of the signal are more or less the intensity of each component and the parameters similar situation.

Demodulation Method of Telemetry Signal Based on Virtual Radio

Yao Xuelu[1,a], Fu Gang[1, a], Li Renlong[1,a]
[1]China Satellite Maritime Tracking and Control Department, China
[a]348237548@sina.com

Keywords: DSTFT, PCM/FM, Demodulation

Abstract. According to the characteristics of PCM / FM signal demodulation method is proposed based on virtual radio platform. This paper discusses in detail the basic principles of this demodulation method and implementation process, analyze the demodulation performance and complexity of the method. Simulation results show that the method for actually received PCM / FM demodulation signal has better performance.

Introduction

At present, foreign countries have launched a software-based virtual radio station of GSM technology, virtual radar (virtual radar) GPS receiver and software aspects of the study, there have been domestic software of digital TV.[1-3]

PCM / FM signal is the current data transmission system is widely used as a signal type. Since the actual received PCM / FM signals and more non-stationary random signal, non-stationary random signal processing usually time-frequency analysis method. Based virtual radio signal demodulation technology, not only to reach a certain demodulation performance, but also to reduce as much as possible the signal demodulation algorithm and computation complexity, thus contributing to the signal processing software design and real-time signal processing.

1 PCM / FM signal characteristic analysis

PCM / FM telemetry signal field called continuous phase frequency shift keying (CPFSK) signals, the mathematical expression is:

$$S_{FM}(t) = A\cos\left[2\pi(f_c + f_d)t + K_{FM}\int f(t)dt\right] \tag{1}$$

Symbols "1" and "0" respectively corresponding to the carrier frequency:

$$f_1 = f_c + f_d + K_{FM} \times R_b \tag{2}$$

$$f_0 = f_c + f_d - K_{FM} \times R_b \tag{3}$$

Therefore, PCM / FM signals within one symbol can be regarded as the width of a single carrier frequency n (I) sinusoidal signals, by alternating two different carrier frequencies, digital data "0" "1" and transmission. Then, within one symbol width PCM / FM signal may be expressed as:

$$x(n) = A\exp[j(2\pi f_i n + \varphi)] + z(n) \qquad (n = 0,1,\cdots,N_w - 1) \tag{4}$$

Equation (4) and can be represented as $X = A_c E + Z$, where,

$$\begin{cases} X = [x(0) \quad x(1) \quad \cdots \quad x(N_w - 1)]^T \\ E = [\quad 1 \quad e^{j2\pi f_i} \cdots \quad e^{j(N_w-1)2\pi f_i}\ ]^T \\ Z = [z(0) \quad z(1) \quad \cdots \quad z(N_w - 1)]^T \end{cases} \tag{5}$$

$\hat{A}_c$ is the amplitude of the signal amplitude A Unbiased MLE estimates.

$$A = \left|\hat{A}_c\right| = \frac{E^H X}{E^H E} = \frac{1}{N_w}\left|\sum_{n=0}^{N_w-1} x(n)e^{-j2\pi f_i n}\right| \tag{6}$$

Since the PCM/FM signal represents "0" and "1" and a known carrier frequency, thus calculation of the signal amplitude X in f_0 / f_s , and f_1 / f_s are:

$$\begin{cases} a = \left| \frac{1}{N_w} \sum_{n=0}^{N_w-1} x(n) e^{-j2\pi(f_0/f_s)n} \right| \\ b = \left| \frac{1}{N_w} \sum_{n=0}^{N_w-1} x(n) e^{-j2\pi(f_1/f_s)n} \right| \end{cases} \tag{7}$$

In summary, according to the spectral characteristics of PCM / FM signal, the DFT method can be used by comparing the size of the amplitude of two frequency and demodulate the PCM / FM signal.

2 Demodulation method based DSTFT

$x(n)(n = 0,1,\cdots,N-1)$ DFT is defined as:

$$X(k) = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{N}nk} \quad (\text{k=0,1,....N-1}) \tag{8}$$

The x (n) make (r-1)N zero, r is an integer such as some integer $k = rN * f / f_s$, whereby rN point sequence x'(n):

$$x'(n) = \begin{cases} x(n), & n = 0,1,...N-1 \\ 0, & n = N, N+1,....rN-1 \end{cases} \tag{9}$$

$$X'(k) = \sum_{n=0}^{rN-1} x'(n) e^{-j\frac{2\pi}{rN}nk} = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{rN}nk} = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{N}\frac{k}{r}n} \tag{10}$$

At this point f_i by frequency DSTFT energy calculated by the formula:

$$DSTFT_x(n,k_i) = \sum_{M=0}^{M-1} \tilde{x}(m,n) e^{-j\frac{2\pi}{M}k_i m} \quad (k_i = M * f_i / f_s) \tag{11}$$

During the sliding of the rectangular window, for each quantitative calculation DSTFT 2 complex multiplications and two complex additions.

$$\begin{aligned} DSTFT(n+1,\omega) &= \sum_{m=0}^{M-1} x(n+1+m) e^{-j\omega m} \\ &= \sum_{m=1}^{M} x(n+m) e^{-j\omega(m-1)} \\ &= e^{j\omega} \sum_{m=1}^{M-1} x(n+m) e^{-j\omega m} + x(n+M) e^{-j\omega(M-1)} \\ &= e^{j\omega} \left(\sum_{m=0}^{M-1} x(n+m) e^{-j\omega m} - x(n) e^{-j0} \right) + x(n+M) e^{-j\omega(M-1)} \\ &= e^{j\omega} [STFT(n,\omega) - x(n)] + x(n+M) e^{-j\omega(M-1)} \end{aligned} \tag{12}$$

3 Performance Analysis

Assuming the frequency of the current signal is the width of the window f_0, the noise is not considered, namely:

$$x(n) = A \cdot e^{j[2\pi(f_0/f_s)n+\varphi]} \tag{13}$$

By DSTFT calculated the energy spectrum of the signal at the frequency of 0, 1:

$$a^2 = \left| A \sum_{n=0}^{N_w-1} e^{j[2\pi(f_0/f_s)n+\varphi]} \cdot e^{-j2\pi(f_0/f_s)n} \right|^2 = \left| AN_w e^{j\varphi} \right|^2 = A^2 \cdot {N_w}^2 \tag{14}$$

$$b^2 = \left| A \sum_{n=0}^{N_w-1} e^{j[2\pi(f_0/f_s)n+\varphi]} \cdot e^{-j2\pi(f_1/f_s)n} \right|^2 \tag{15}$$

Assuming $\Delta f = (f_1 - f_0)/f_s = 2K_{FM} \times R_b / f_s$,

$$b^2 = A^2 \cdot \left| \frac{1-e^{j2\pi N_w \Delta f}}{1-e^{j2\pi\Delta f}} \right|^2 \qquad = A^2 \cdot \frac{1-\cos 2\pi N_w \Delta f}{1-\cos 2\pi\Delta f} \tag{16}$$

So,

$$\rho_0 = \frac{b^2}{a^2} = \frac{1-\cos 2\pi N_w \Delta f}{N_w{}^2(1-\cos 2\pi\Delta f)} = \frac{\sin^2 \pi N_w \Delta f}{N_w{}^2 \sin^2 \pi\Delta f} = \frac{\sin^2 N_w \dfrac{\Delta\omega}{2}}{N_w{}^2 \sin^2 \dfrac{\Delta\omega}{2}} \tag{17}$$

The relationship between ρ_0 and $\Delta\omega$ shown in Figure 1. The relationship between ρ_1 and $\Delta\omega$ shown in Figure 2.

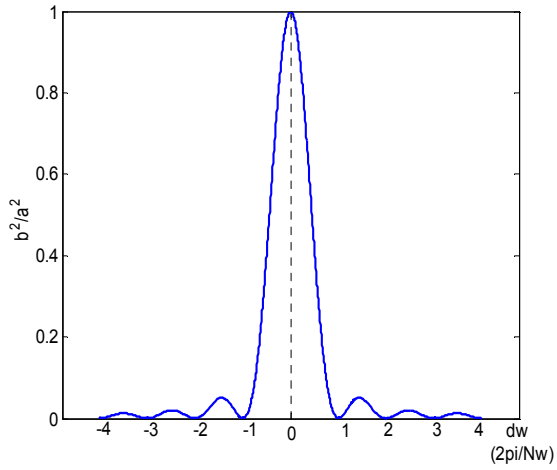

Fig1 The relationship between ρ_0 and $\Delta\omega$

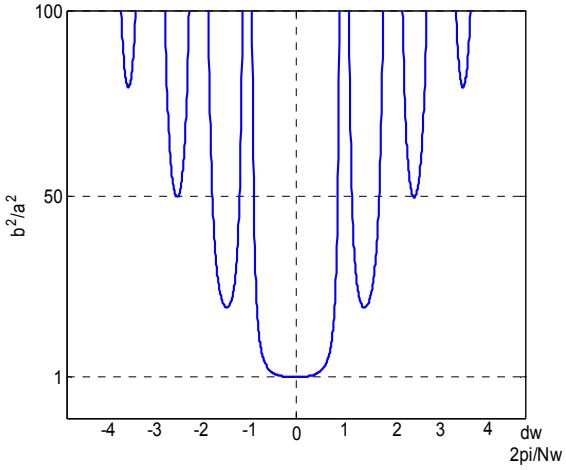

Fig2 The relationship between ρ_1 and $\Delta\omega$

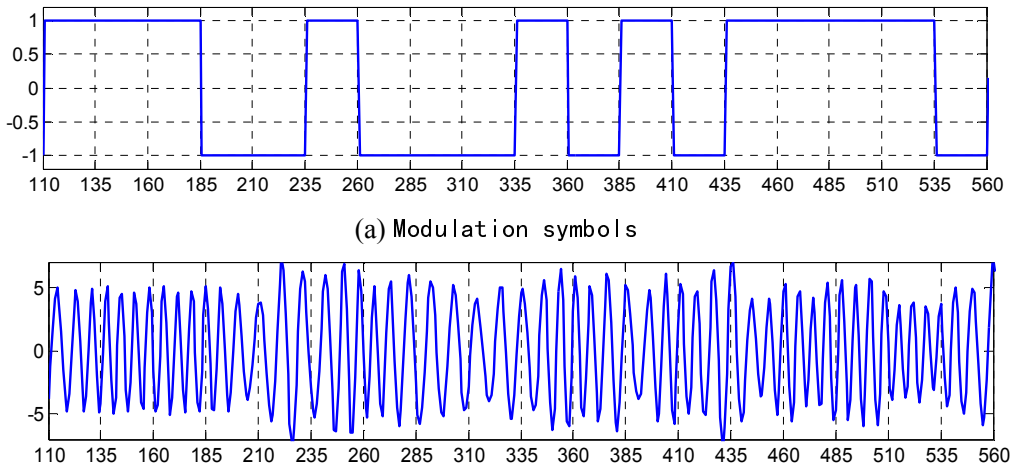
Use MatLab simulation program written by computer demodulation actually received PCM / FM signal, the signal waveform shown in Figure 3, (a) represents the modulation symbols, (b) shows the modulation symbols corresponding PCM / FM time-domain waveform.



(a) Modulation symbols

(b) PCM/FM signal

Fig3 Ideal PCM/FM signal

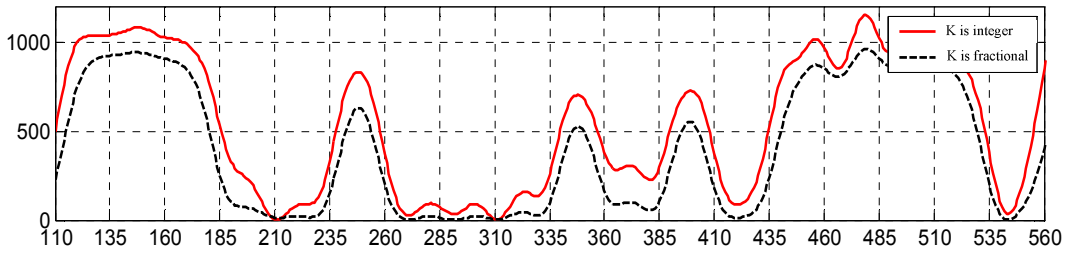


Fig4 Affect the value of K frequency energy

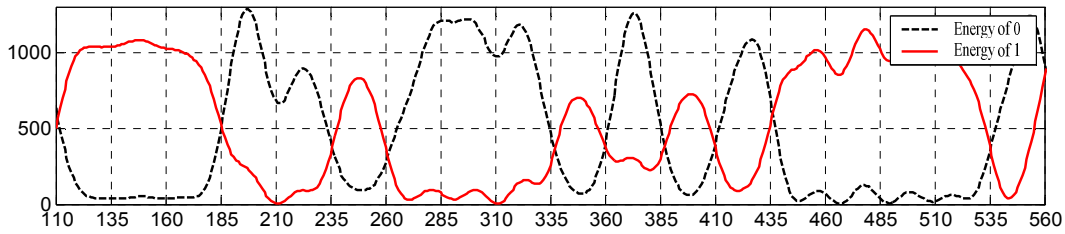

Fig5 PCM / FM signal frequency energy variation

According to "eye" in width and the size relationship between f_0 and f_1 energy can demodulate the PCM / FM signal.

Using current mainstream computer configuration, recorded on the hard disk where the data is processed using a signal demodulation speed of 1:5, the average SNR of 12.8dB signal error rate of 1.871×10^{-4}, to reach the current demodulation performance hardware devices.

Summary

According to the spectral characteristics of PCM / FM signal, the method used to calculate the energy STFT PCM / FM signal frequency points f_1 and f_0, by comparing the two laws of variation of size and frequency of energy, demodulate the signal. The demodulation method is simple, strong interference suppression capability, ease of computer software programming.

Keywords: Multi-frequency, IIR , Frequency Estimator

Abstract. Presents a IIR adaptive frequency estimator to achieve multi-frequency estimation algorithm. More traditional phase-locked loop algorithm, which has no mixing components, to achieve the advantages of full-band frequency estimation, frequency estimation accuracy under the same environment and phase-locked loop fairly.

Introduction

The traditional use of PLL frequency estimation, due to the transition from analog digital phase-locked loop is coming, there is a value to adjust the design parameters of the experience, it is difficult to establish a precise mathematical model. But most of the traditional methods for frequency estimator only a single point estimate frequency signal frequency range of applications is limited. This paper analyzes proceed from the IIR filter performance, making multi-point IIR adaptive frequency estimation frequency estimate possible.[1-3]

1 Adaptive filter theory and analysis of variance

Single-point frequency signal estimation commonly used second-order adaptive filters. As shown, the waveform of the original input signal and a noise is mixed, wherein the noise signal is not relevant; another path of the reference input signal is uncorrelated with the noise-related signals. IIR filter transfer function is:

$$H(z)=\frac{1+\rho_1 az^{-1}+\rho_1^2 z^{-2}}{1+\rho_2 az^{-1}+\rho_2^2 z^{-2}} \tag{1}$$

$0\le\rho_1\le 1$, $0\le\rho_1<\rho_2\le 1$.

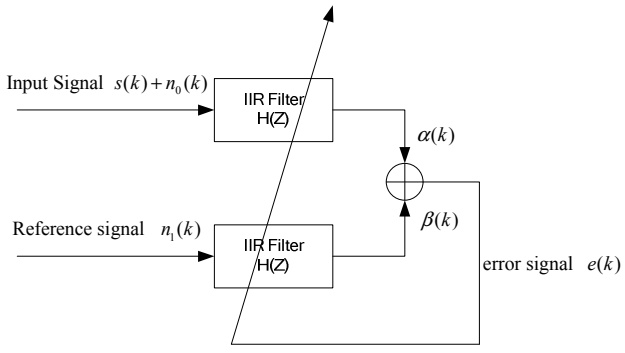

Fig1 Adaptive filtering schematics

The error signal may be obtained by Equation 2:

$$e(k)=\alpha(k)-\beta(k) \tag{2}$$

$$E[e^2]=E[\alpha^2]+E[\beta^2]-2E[\alpha\beta] \tag{3}$$

$$E[e^2]=\frac{1}{2\pi j}\{\oint P_{ss}|H(z)|^2\frac{dz}{z}+\oint P_{nn}|H(z)|^2\frac{dz}{z}-2\oint P_{sn}|H(z)|^2\frac{dz}{z}\} \tag{4}$$

Wherein, P_{ss} , P_{nn} and P_{sn} respectively of the input signal, the reference signal and their associated power spectrum.

$$E[e^2]=\frac{1}{2\pi j}\oint|H(z)|^2\{P_{ss}+P_{nn}-2P_{sn}\}\frac{dz}{z} \tag{5}$$

$$\frac{\partial E[e^2]}{\partial a}=\frac{1}{2\pi j}\oint\frac{|H(z)|^2}{\partial a}\{P_{ss}+P_{nn}-2P_{sn}\}\frac{dz}{z} \tag{6}$$

$$\frac{\partial|H(z)|^2}{\partial a}=\frac{\frac{\partial(AA^*)}{\partial a}BB^*-AA^*\frac{\partial(BB^*)}{\partial a}}{(BB^*)^2} \tag{7}$$

$$=\frac{BB^*[\rho_1 z^{-1}A^*+\rho_1 zA]-AA^*[\rho_2 z^{-1}B^*+\rho_2 zB]}{[BB^*]^2}$$

$$=\frac{2zA(\rho_1 B^*-\rho_2 A^*)}{|B|^2 B^*}$$

To analyze the extreme points, so $\frac{\partial E[e^2]}{\partial a}=0$, can be obtained:

$$\rho_1+\rho_1\rho_2 az+\rho_1\rho_2^2 z^2=\rho_2+\rho_1\rho_2 az+\rho_2\rho_1^2 z^2 \tag{8}$$

$$z=\frac{1}{\rho_1\rho_2} \tag{9}$$

As can be seen from Equation 9, Equation unconditional extremum exists. Figure 2 is a relationship between $H(z)$, a and ρ_2.

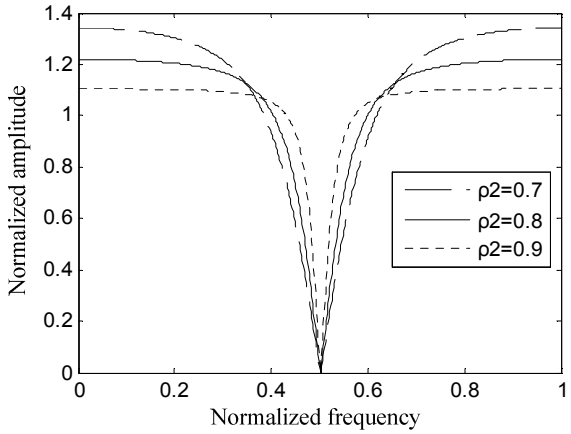

Fig2 Second-order filter frequency response ($f=0.5$， $\rho_1=1$)

Multi-frequency signal estimation must use higher-order adaptive filters. Through the two-channel adaptive filter performance characteristics of high-level analysis can be effectively overturned the adaptive filter. Dual-channel transfer function of the filter is:

$$H(z)=\frac{(1+\rho_1 a_1 z^{-1}+\rho_1^2 z^{-2})(1+\rho_1 a_2 z^{-1}+\rho_1^2 z^{-2})}{(1+\rho_2 a_1 z^{-1}+\rho_2^2 z^{-2})(1+\rho_2 a_2 z^{-1}+\rho_2^2 z^{-2})}$$

$$=\frac{k_0+\rho_1 k_1 z^{-1}+\rho_1^2 k_2 z^{-2}+\rho_1^3 k_3 z^{-3}+\rho_1^4 k_4 z^{-4}}{k_0+\rho_2 k_1 z^{-1}+\rho_2^2 k_2 z^{-2}+\rho_2^3 k_3 z^{-3}+\rho_2^4 k_4 z^{-4}} \tag{10}$$

Among, $a_1=-2\cos\omega_1$， $a_2=-2\cos\omega_2$， $k_0=k_4=1$， $k_1=k_3=a_1+a_2$， $k_2=a_1a_2+2$。

$$E[e^2]=\frac{C_1^2}{2}\left|H(e^{j\omega_1})\right|^2+\frac{C_2^2}{2}\left|H(e^{j\omega_2})\right|^2+\frac{1}{2\pi j}\oint|H(z)|^2\{P_{n_1n_1}+P_{n2n2}-2P_{n1n2}\}\frac{dz}{z} \tag{11}$$

$$\frac{\partial E[e^2]}{\partial k_1}=\frac{1}{2\pi j}\oint\frac{\partial|H(z)|^2}{\partial k_1}\{P_{n_1n_1}+P_{n2n2}-2P_{n1n2}\}\frac{dz}{z} \tag{12a}$$

$$\frac{\partial E[e^2]}{\partial k_2}=\frac{1}{2\pi j}\oint\frac{\partial|H(z)|^2}{\partial k_2}\{P_{n_1n_1}+P_{n2n2}-2P_{n1n2}\}\frac{dz}{z} \tag{12b}$$

Assume $\frac{\partial E[e^2]}{\partial k_1}=0$, $\frac{\partial E[e^2]}{\partial k_2}=0$,Can be deduced:

$$\oint \rho_2 \frac{Az^{-1}(1+\rho_2^2 z^{-2})+Az(\rho_2^2+z^2)dz}{BB^* z} = \oint \rho_1 \frac{AA^*[Bz^{-1}(1+\rho_2^2 z^{-2})+Bz(\rho_2^2+z^2)]dz}{BB^* BB^*}$$

$$\oint \rho_1^2 \frac{(A^* z^{-2}+Az^2)dz}{BB^* z} = \oint \rho_2^2 \frac{AA^*[Bz^{-2}+Bz^2]dz}{BB^* BB^* z} \tag{13}$$

Among, $A=1+k_1\rho_2 z^{-1}+k_2\rho_2^2 z^{-2}+k_1\rho_2^3 z^{-3}+z^{-4}$, $B=1+k_1\rho_1 z^{-1}+k_2\rho_1^2 z^{-2}+k_1\rho_1^3 z^{-3}+z^{-4}$.

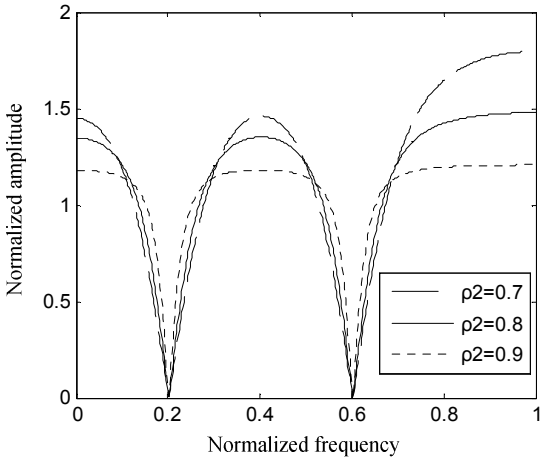

Fig3 Higher-order filter frequency response ($f_1=0.2$, $f_2=0.6$, $\rho_1=1$)

It can be concluded from Figure 4: High adaptive filter only when the signal carrier frequency and the center frequency of the narrowband process is controlled within a proper range away from the filter in order to achieve convergence.

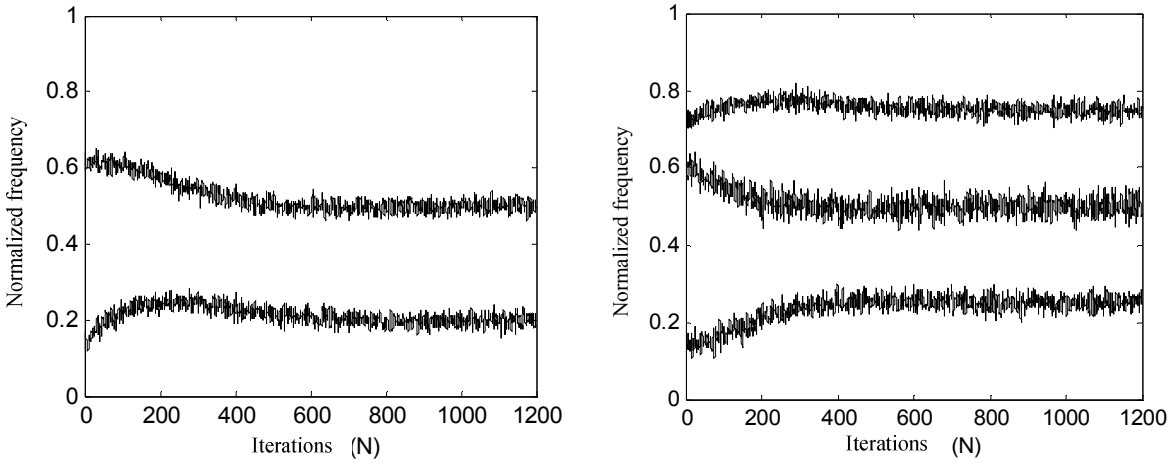
2 Performance Analysis

The main performance simulation using two-point and three-frequency signal frequency signal frequency estimation. Figure 5 is a carrier-to-noise ratio 30dBHz multi-frequency signal frequency tracking, the initial frequency of the filter has been estimated by the FFT. Figure 6 Comparison of IIR adaptive filter with conventional phase-locked loop tracking performance. Simulation results show that the FFT frequency assisted adaptive IIR filter may be implemented with an estimated multi-frequency signal frequency point; under different conditions IIR adaptive filter has a bandwidth of the phase locked loop similar to the tracking accuracy.



(a) Dual-band point signal($f_1 = 0.2$, $f_2 = 0.5$) (b) Three frequency signals ($f_1 = 0.3$, $f_2 = 0.5$, $f_3 = 0.8$)

Fig5 Multi-frequency signal parameter estimation curve

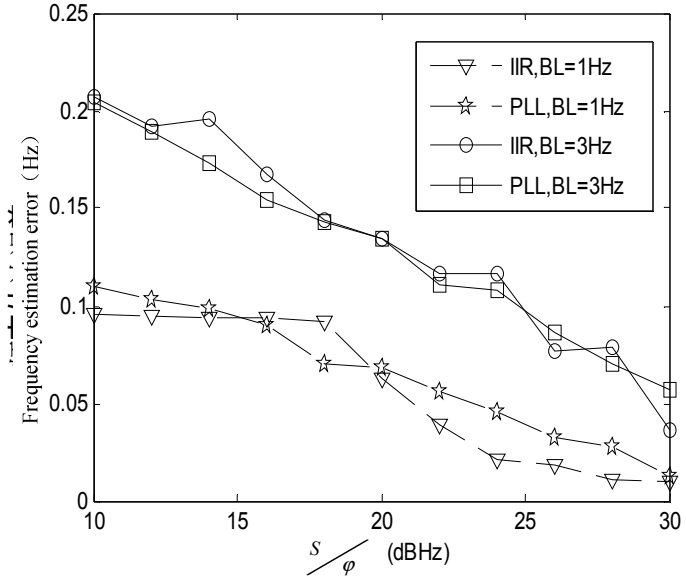


Fig6 Compared with different carrier-to-noise PLL frequency tracking error ratio IIR

Summary

By analyzing the second-order and fourth-order IIR filter that affect the variance adaptive prove second-order IIR model has a single peak characteristics, to achieve stable convergence; while the higher-order IIR model polymorphism, and therefore need to estimate parameters conclusions initialization.

Keywords: Chirp signal; Wigner-Ville distribution(WVD); Radon-Wigner transform (RWT); fractional Fourier transform(FRFT)

Abstract. Based on the relationship between the Radon-Wigner transform and fractional Fourier transform and the time frequency distribution, using the property that Radon-Wigner transform has better performance in time and frequency domain, detection and parameter estimation of Chirp signal have been done by Radon-Wigner transform or fractiona1 Fourier transform. The theoretica1 analysis and simulation prove that two techniques are better than generic time-frequency transform, such as Wigner-Ville transform.

1 Introduction

In the time-frequency analysis, Wigner-Ville transform is a commonly used method, the analysis of non-stationary signals is very favorable. However, the definition of the Wigner-Ville transform apparent: it is essentially a bilinear transformation, the multi-component cross term signal will appear, especially when the signal contains two or more components, each of the components will produce cross between term, this is a major flaw in WVD. Radon-Wigner transform and fractional Fourier transform analysis of multi-component signals; you can effectively reduce or avoid the impact of such interference.[1][2]

Wigner-Ville distribution WVD ideal LFM signal was linear impulse function, finite length of Chirp signal is shaped dorsal fin, to its time-frequency plane along the corresponding WVD straight points to make smooth, energy WVD of the corresponding points in a straight line been gathered on, Radon-Wigner transform (RWT) is a linear integral projection transformation; fractional Fourier transform is the signal frequency distribution in the projection after the frequency axis of rotation, if the rotation angle is right, you can get LFM signal energy distribution of fractional gathered Fourier domain. Therefore, Radon Wigner transform and fractional Fourier transform for Chirp signal analysis is the ideal choice.

2 RWT and FRFT

2.1 Radon-Wigner transform

Radon-Wigner WVD of signal conversion is done straight integral projection of Radon transform, collectively referred to as the signal to make R a don transformation.

As shown in Figure 1, the original Cartesian coordinate system (t,ω) rotation angle α to obtain the new Cartesian coordinate (u,v) . u value at different time in parallel to the v axis points, the result is Radon transformation.

As we can be seen from Figure 1, Radon transform is actually equivalent to the generalized edge points, the equivalent of a projection points. Let two-dimensional plane (t,ω) has an arbitrary two-dimensional function (such as density function) $f(t,\omega)$, then the use of trigonometry, its Radon transform can be written as:[3]

Radon transform $P_\alpha(u)$ certain corner of α is a function u (equivalent to PQ line pan). For different values of α, $P_\alpha(u)$ is a function of the value change, and that it is a two-dimensional function of u and α .If R represents Radon transform operator, the transformation from the normal two-dimensional function $f(t,\omega)$ of the object instead of the signal $s(t)$ Wigner-Ville distribution

(WVD), converting the resultant Radon is the signal of Radon-Wigner transform(RWT), represented by a symbol $D_z(u,\alpha)$. By the formula (1) readily obtained:

$$P_\alpha(u)=\int_{PQ} f(t,\omega)dv=\int_{PQ} f(u\cos\alpha-v\sin\alpha,u\sin\alpha+v\cos\alpha)dv \tag{1}$$

$$\begin{aligned} D_z(u,\alpha)&=R_\omega[z(t)]=R[W_z(t,\omega)]=\int_{PQ} W_z(u\cos\alpha-v\sin\alpha,u\sin\alpha+v\cos\alpha)dv \\ &=\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} W_z(u\cos\alpha-v\sin\alpha,u\sin\alpha+v\cos\alpha)\delta(u-u)dudv \end{aligned} \tag{2}$$

Where, $W_z(t,\omega)=\int_{-\infty}^{+\infty} z(t+\frac{\tau}{2})z^*(t-\frac{\tau}{2})e^{-j\omega\tau}d\tau$ is WVD of the signal $s(t)$; the real signal $s(t)$, $z(t)$ is the analytic signal of the signal $s(t)$, $z(t)=s(t)+j\cdot HLT(s(t))$; HLT represents signal indicates Hilbert (Hilbert) transformation.[4]

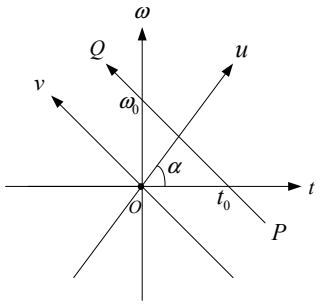

Fig 1 The axis of rotation of the coordinate geometry relations

Formula (2) represents signal $s(t)$ of Radon-Wigner transform that is represented by parameter (u,α). In Radon-Wigner distribution frequency plane, where the practice of using ω_0 and m of axes ω as a parameter to indicate the slope of the straight line. Therefore, when necessary points along a straight line $\omega=\omega_0+mt$, in Figure 1 may be integral path (straight line PQ) replace the parameters of (u,α) to (m,ω_0), and the relationship between the two parameters as follows:

$$m=-\cot\alpha,\quad \omega_0=u/\sin\alpha \tag{3}$$

Find a signal $s(t)$ of Radon-Wigner transform, and parameter (m,ω_0) represents the integral path, then

$$\begin{aligned} D_z(u,\alpha)&=\int_{PQ} Wz(t,\omega)dv=\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} W_z(t,\omega)\cdot\delta(u-u)dudv \\ &=\frac{1}{|\sin\alpha|}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty} W_z(t,\omega)\delta[\omega-(\omega_0+mt)]d\omega dt \\ &=\frac{1}{|\sin\alpha|}\int_{-\infty}^{+\infty} W_z(t,\omega_0+mt)dt\Big|_{\substack{\omega_0=u\sin\alpha\\ m=-\cot\alpha}} \end{aligned} \tag{4}$$

Formula (4) shows: If $s(t)$ is the parameters ω_0 and m are the Chirp signal, the maximum integral value; when the parameter ω_0 and m, when departing from the integrated value decreases rapidly, it is a certain Chirp signal, the Radon-Wigner transform spikes will appear at the corresponding parameter (m,ω_0), which can Chirp signal detection and parameters estimation.

2.2 fractional Fourier transform (FRFT)

Fractional Fourier transform (FRFT) is also based on the principle axes of rotation. Traditional Fourier transform function $g(t)$ is changed $\pi/2$ to ω rotational axis of said formula, denoted by $G=Fg$, the function of the angle $\pi/2$ of the ω axis of said shaft, is a function of converting the Fourier transform. It is easy to verify that: $F^2g(t)=FFg(t)=g(-t)$ and $F^4g(t)=g(t)$; where F^n represents the continuous use of the operator F n times. Figure 1 when the rotation angle α is not

equal to whole multiple of $\pi/2$, the function is obtained in the angle α of the axis u shaft of said fractional Fourier transformation. Let this time as a linear operator R, the function $x(t)$ fractional Fourier transform is defined as

$$X_p(u)=\left\{R^p x\right\}(u)=\int_{-\infty}^{+\infty}x(t)K_p(t,u)dt=\begin{cases}\sqrt{\dfrac{1-j\cot\alpha}{2\pi}}e^{j\frac{u^2}{2}\cot\alpha}\displaystyle\int_{-\infty}^{+\infty}x(t)e^{j\frac{t^2}{2}\cot\alpha}e^{-jut\csc\alpha}dt, & \alpha\neq n\pi\\ x(u) & \alpha=2n\pi\\ x(-u) & \alpha=(2n+1)\pi\end{cases}\tag{5}$$

Where: $\alpha=p\pi/2$, p is the order of FRFT, when $p=1$, the degradation of the traditional Fourier transform.

According to the concept of rotation, the operator R has the following properties: (1)zero rotation of $R^0=I$; (2)and Fourier transform equivalence $R^{\pi+2}=F$; (3) rotation addition $R^{\alpha}R^{\beta}=R^{\alpha-\beta}$; (4)the identity transformation $R^{2\pi}=I$.

Chirp signal when said frequency plane was inclined blade-like, with a clear time-frequency coupling characteristics. When the projector and fractional Fourier transform can be seen as a signal of the frequency distribution in the frequency axis rotated; conventional Fourier transform can be seen as a signal when the frequency distribution in the projection frequency axis, linear FM signal spectrum is broadened If the rotation angle is right, you can get the energy chirp signal gathering fractional Fourier domain distribution, which is the use of the basic principle of fractional Fourier transform to detect the chirp signal. For two different slopes FM chirp signal, choose a different rotation angles can be two separate, in order to estimate the parameters of the signal.

3 Chirp signal detection and parameter estimation

Chirp signal WVD for a good time and frequency aggregation, which is bilinear transformation. Due to the nature of the algorithm. The way to solve this problem is that demand for WVD LFM signal or directly to the Radon transform signal fractional Fourier transform.

Figure 2 shows the estimated flow detection and parameter time-frequency signal analysis ILFM based. The upper part of the figure has the upper and lower two-way, all the way to select any one time (controlled by a switch). The road to signal Radon-Wigner transform, the input signal is first calculated Wigner-Ville distribution, the time-frequency distribution after Radon transform signal can be obtained Radon-Wigner transformation; under way to signal the fractional Fourier transform, whichever is the square of the modulus value again. Upper and lower road use Radon-Wigner transformation respectively and fractional Fourier transform modulus squared value for signal detection and parameter estimation.

From the foregoing: Because Chirp signal in the time-frequency plane, the frequency is approximately linear variation with time $\omega=\omega_0+mt$, the value of the square modulus of its Radon-Wigner transform and FRFT, it will show a peak at the corresponding parameters (u,α), the peak corresponding value of the coordinate u and α ,we can calculated linear parameter $m=-\cot\alpha$, $\omega_0=u/\sin\alpha$.

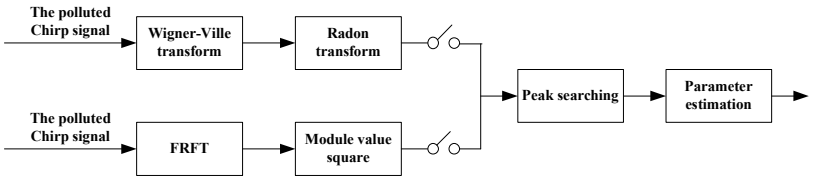

Fig 2 Flow chart of Chirp signal detection and parameters estimation based on time-frequency analysis

Assuming unknown signal $x(t)=s(t)+n(t)$, where, $s(t)=e^{j2\pi(f_0t+\frac{1}{2}mt^2)}$ is chirp signal, $n(t)$ is Gaussian white noise.

Table1 Chirp signal parameters estimation based on Radon-Wigner transform

The polluted Chirp signal	SNR(dB)	Parameter representation form					
		Parameters setting		Estimated parameters		Relative error(%)	
		$f_0(Hz)$	$k(Hz/s)$	$f_0'(Hz)$	$k'(Hz/s)$	$(f_0-f_0')/f_0$	$(k-k')/k$
Signal 1	-2	-30	100	-30.3051	99.6816	1.02	0.32
Signal 2	0	100	4000	98	4009	2.00	0.22
Signal3	4	300	-2000	303	-2020	1.20	0.17

Table2 Chirp signal parameters estimation based on FRFT

The polluted Chirp signal	SNR(dB)	Parameter representation form					
		Parameters setting		Estimated parameters		Relative error(%)	
		$f_0(Hz)$	$k(Hz/s)$	$f_0'(Hz)$	$k'(Hz/s)$	$(f_0-f_0')/f_0$	$(k-k')/k$
Signal 1	-2	-30	100	-29.9664	99.7265	1.12	0.27
Signal 2	0	100	4000	101	4008	1.00	0.20
Signal3	4	300	-2000	298	-1993	0.67	0.35

Set different chirp parameters (center frequency and frequency modulation), respectively, parameters and fractional Fourier transform detected (U, a) transform the Radon-Wigner, can estimate the center frequency and modulation frequency, as shown in Table 1 and Table 2 shown. The table also shows the relative error of the estimated parameters and the chirp parameter setting. Visible, the estimation error is small. This is because the cross-term Radon-Wigner distribution, affecting the resolution of the signal parameter estimation; while fractional Fourier transform is a linear transformation, without interference from cross-terms. Nevertheless, Radon-Wigner transformation is still an effective LFM signal detection and parameter estimation method.

4 Summary

By the theoretical analysis and computer simulation, we can see: the use of LFM signal Wigner-Ville distribution in the time-frequency plane is approximately linear relationship was characterized by its WVD seeking Radon transform of the signal with the direct fractional Fourier transform, not only can detect the noise LFM the existence and the number of component signals LFM signals, but also to estimate the parameters of each LFM signal components; especially for multi-component LFM signal detection and parameter estimation, Radon-Wigner transform and fractional Fourier transform more than Wigner-Ville transform effective.

Keywords: Fractional Fourier Transform, Chirp signal, Wigner-Ville distribution, Waveform Reconstruction

Abstract: The fractional Fourier transform (FRFT) is a generalization of the Fourier transform. The article first introduces the definition of FRFT transformation; then analyzed FRFT Chirp signal based on this humble proposed restoration Chirp signal in a noisy background in two ways: one is based on parameter estimation, and the other is based on the scores Fourier domain filtering to achieve signal reconstruction; Finally, simulation verify the feasibility of the above analysis.

Introduction

Chirp signal is a special kind of non-stationary signals. As a large time-bandwidth product signals, it is widely in communications, radar, sonar and seismic exploration systems. In such systems, Chirp signal detection, parameter estimation and signal recovery is an important research topic. FRFT concepts from the field of optics was first introduced, it reflects the lens rear light intensity distribution in a plane perpendicular to the optical axis. In the mid-1990s, the method was introduced signal processing, and pointed out that it is the physical meaning of a given signal frequency distribution in the frequency domain with a timeline angled α integral projection axis. FRFT is a linear transformation, it wavelet transform, Wigner-Ville distribution (WVD) has a close relationship, so frequent in recent years, this method as a research tool to analyze the signals received wide attention of researchers, the corresponding discrete transform algorithms have been proposed.[1]

The article first introduces the definition and implementation of FRFT transform, and then analyzes the FRFT Chirp signal based on this proposed restoration Chirp signal in a noisy background of the two methods, verified by simulation analysis above.

1 Definition of FRFT

Fourier transform is a linear operator, the operator's role can be seen in the time-frequency plane rotation $\pi/2$, that is, from the timeline to the frequency axis. Understandably, if you find any angle $\alpha = p\pi/2$ can be used for a non-integer multiple (non-integer multiple of $\pi/2$, and p is a fraction) rotation operator,[2] the signal represented by the new operator is available, the so-called fractional Fourier transform (referred FRFT).

p th order FRFT of signal $x(t)$ is defined as

$$X_p(u) = \{F^p x(t)\}(u) = \int_{-\infty}^{+\infty} x(t) K_p(t,u) dt \tag{1}$$

Where $K_p(t,u)$ is a nuclear transformation, which is defined as

$$K_p(t,u) = \begin{cases} \sqrt{\dfrac{1-j\cot\alpha}{2\pi}} \exp[j(\dfrac{1}{2}u^2\cot\alpha - ut\csc\alpha + \dfrac{1}{2}t^2\cot\alpha)] & \alpha \neq n\pi \\ \delta(t-u) & \alpha = 2n\pi \\ \delta(t+u) & \alpha = 2(n+1)\pi \end{cases} \tag{2}$$

Where n is an integer number.

As can be seen from the definition, FRFT is generalized Fourier transform classic form, it contains a signal of time domain and frequency domain representation, when the rotation angle is $\frac{\pi}{2}$, that means the 1 order of FRFT is a traditional Fourier transform ; does not rotate when the rotation angle of 2π or an integer multiple of the result is the signal itself; when the rotation angle is not more than two positions, when p is a fraction numbet, it scores from the time domain and it also gives the frequency domain characteristics of the signal. FRFT corresponding inverse transform $-\alpha$ angle FRFT.[3]

2 Fractional Fourier Transform Chirp signal characteristics and recovery

Assuming a single frequency chirp signal $f(t)=\exp\left[2\pi j(f_0 t+\frac{1}{2}t^2)\right]$, Its Wigner-Ville distri -bution as

$$W(f,t)=\delta\left[f-(kt+f_0)\right] \tag{3}$$

According rotational invariance of Wigner-Ville distribution, as long as the rotation angle of the α and β FRFT orthogonal as shown in Figure1. Then the Chirp signal is projected onto a fractional Fourier domain should be gathered at one point. According FRFT definition, fractional Fourier transform domain decomposition based tone frequency is $-\cot\alpha$ ($\alpha=k\pi(k=0,\pm1,...L)$ here ignores the special circumstances), while the expression of available FM Chirp signal was $k=\tan\beta$, Chirp signal in order to achieve a base focus on the frequency must be adjusted to ensure equal as

$$\tan\beta=-\cot\alpha=k \tag{4}$$

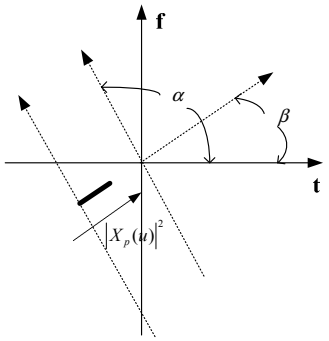

Fig1 FRFT of Chirp and its Wigner-Ville distribution

Here are Chirp signal recovery method.

The first method: Depending on the nature of the known FRFT it is a linear transformation, is a continuous function of p, so the fractional Fourier transform with $\alpha=p\pi/2$ angleis the angle $\alpha=-p\pi/2$ with the FRFT, that is

$$x(t)=\int_{-\infty}^{+\infty}X_p(u)K_{-p}(t,u)\,du \tag{5}$$

from a recovery directly out of the original signal.

If Chirp signal is finite length signal, then it's most of the energy in the u domain concentrated in u_0. Center within a narrow band, but there is no good time-frequency noise of focusing on fractional Fourier domain, so in the case of additive Gaussian noise conditions, the design of an appropriate bandpass filter centered in u_0, then the output signal can retain most of the energy and filter out most of the noise energy, then filtered output FRFT inverse transform, we can recover the original Chirp signal.

The second method: Chirp signal characteristics with energy gathered in FRFT certain angle, namely Chirp signal in the new coordinate system (u,v) has an impact alpha function and meet FM slope $k=-\cot\alpha$. Thus, the continuous search for α, once the shock exists, then the Chirp signal is present, and to meet FM slope $k=-\cot\alpha$; estimated slope of the FM signal k, you can calculate

the angle of its FRFT $\alpha = arc\cot(-k)$, and then seek the order of the FRFT, then search out the maximum point u_0 fractional coordinates on u, can be estimated Taking into account the initial beta frequency signal $f_0 = u_0 \csc\alpha$; Finally, according to the expression Chirp signal to recover the original signal.

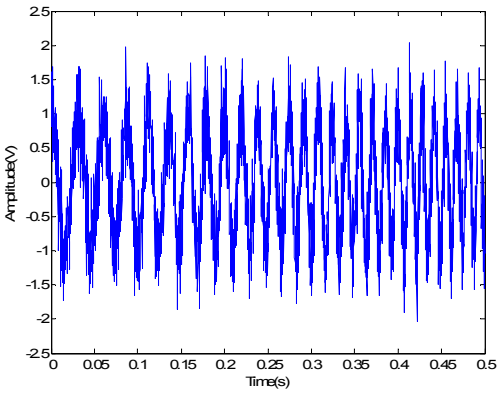
3 Simulation analysis

To illustrate the effectiveness of the algorithm, the following assumes a bandwidth of $B = 200MHz$, FM was $k = 2\times10^{13} Hz/s$, initial frequency $f_0 = 100MHz$ of single-frequency Chirp signal, additive noise is zero mean Gaussian white noise. In the observation period $T = 10^{-6} s$, using the above two methods with different SNR, the simulation results shown in Figure 2.

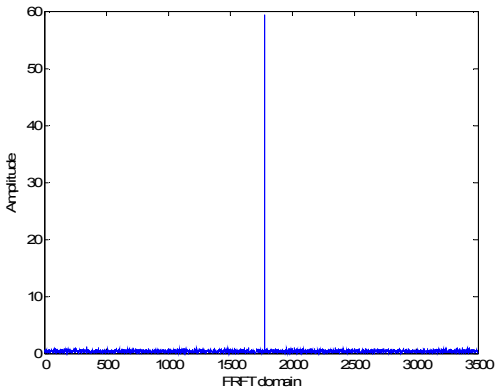
When the SNR is equal to 12dB, the direct use of parameter estimates obtained: $k = 2.0001\times10^{13} Hz/s$, $f_0 = 9.9996\times10^{7} Hz$, relative error of k is 0.005%, the relative error of f_0 was 0.004%; frequency analysis of the signal obtained directly from the inverse transform filter were obtained $k = 2.002\times10^{13} Hz/s$, $f_0 = 1.0001\times10^{8} Hz$, the relative error of k is 0.001% and the relative error of f_0 is 0.01%.

When the SNR is equal to 12dB minus, the direct use of parameter estimates obtained: $k = 2.0003\times10^{13} Hz/s$, $f_0 = 1.0005\times10^{8} Hz$, relative error of k is 0.015%, the relative error of f_0 is 0.005% ; directly after the signal obtained using filtered back-transform time-frequency analysis and gained: $k = 2.0005\times10^{13} Hz/s$, $f_0 = 1.0006\times10^{8} Hz$, relative error of k and f_0 are 0.025%,0.06% respectively.

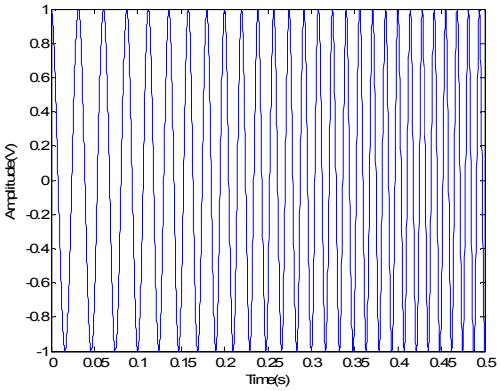
For multi-component signals $x(t)$, generally the first two-dimensional peak search method according to a first position (α_1, u_1) of the maximum peak point of the parameter estimates obtained strongest signal component corresponding to the signal , then calculated at the time of FRFT alpha α_1, in this case most of the energy of the first component is concentrated in a narrow band centered with u_1, u in the domain covered by the spike, and the method according to the second reverse rotation of the filtered signal back to the original time-domain α_1, detecting a second component; repeat the above process, to detect all detectable parameter estimation component until the average amplitude of the remaining signal components below a predetermined threshold.



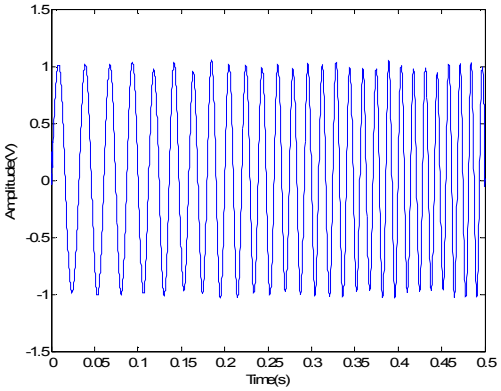
(a) Chirp signal waveform polluted by AWGN



(b) The FRFT peak of two-dimensional peak search



(c) Chirp signal waveform recovered by parameters estimation



(d) Chirp signal waveform recovered by inverse FRFT

4 Summary

Article two methods have their own characteristics. Peak detection method for a more intuitive in principle, can be directly estimated parameters, but in the process variable rotation angle α scan, when the request parameter estimation accuracy is high, you must select a smaller scanning step, making computational complexity increases; followed in the multi-component detection, there is a strong influence on the weak component of the component, and therefore must be taken to suppress this interference, then you need to use the second method uses filtering successive elimination strong way to improve signal detection reliability. However, in the case of frequency modulation is unknown, the filtering method using the premise that accurately estimate a frequency swap, so the need for effective combination of both methods. Clear physical meaning of these two methods, the calculation is simple, no cross-infection, is a very effective method.

Research on Demodulation of Pulse Code Modulated Signal Based on Instantaneous Frequency Measurement

Fu Gang[1, a], Wu Yanjun[1,a] and Feng Yue[1,a]
[1]China Satellite Maritime Tracking and Control Department, China
[a]348237548@sina.com

Keywords: PCM/FM, MSD, synchronous.

Abstract. According instantaneous frequency measurement theory, we propose a new PCM / FM telemetry signal demodulation method. This paper introduces the basic principles of this demodulation method and implementation process, the influence of instantaneous frequency measurement accuracy and the impact of factors on the Doppler frequency demodulation performance is proposed to improve the accuracy and instantaneous frequency measurement method demodulation performance .

Introduction

Currently, PCM / FM signal demodulation software commonly used methods are: using Wigner - Willie (WD) or on the distribution of discrete short-time Fourier transform (STFT),[1] frequency analysis of the signal when the signal is estimated using statistical methods the width of the frequency and the symbol realize PCM / FM demodulation signal; cycle using a sinusoidal model for precise slide fitting method demodulated PCM / FM signal. Although these methods must meet the accuracy of demodulation, but the complexity of the algorithm, a large amount of computation, the signal is not conducive to improved efficiency of the software demodulator.

Instantaneous frequency measurement capable of having a single carrier frequency signal for fast frequency measurement. In this paper, the theory of instantaneous frequency measurement is based on the characteristics of PCM / FM signal, the introduction of software demodulation principle and demodulation process and its performance analysis and simulation.

1 Instantaneous frequency measurement

Assuming a single frequency signal, denoted as:[2]

$$S(i) = A\sin(\omega T_S i + \varphi) \tag{1}$$

There are:

$$S_{i+1} + S_{i-1} = 2S_i \cos(\omega T_s) or \omega T_s = \arccos\left(\frac{S_{i+1} + S_{i-1}}{2S_i}\right) \tag{2}$$

Assuming $S_i \neq 0$, the use of three adjacent sample values, can calculate the frequency of the signal. In the quantization accuracy is high enough, the denominator is not zero in most of the conditions can be met. Practical applications, often with multi-point instantaneous frequency measurement, then equation (2) can be rewritten as:

$$y_i = Kx_i, \qquad y_i = S_{i+1} + S_{i-1}, \quad x_i = 2S_i, K = \cos(\omega T_s) \tag{3}$$

And obtaining the square of the distance:

$$\begin{aligned} &\frac{1}{1+K^2}\sum_{i=1}^{m}(y_i - Kx_i)^2 = m*\left[\frac{W}{1+K^2} - \frac{U*2K}{1+K^2} + \frac{V*K^2}{1+K^2}\right] \\ &\text{among:} W = \frac{1}{m}\sum_{i=1}^{m} y_i^2, U = \frac{1}{m}\sum_{i=1}^{m}(x_i y_i), V = \frac{1}{m}\sum_{i=1}^{m} x_i^2 \end{aligned} \tag{4}$$

The formula for the derivative gain K:

$$U * K^2 + (V - W) * K - U = 0 \tag{5}$$

And then solve:

$$K = \frac{-(V-W) \pm \sqrt{(V-W)^2 + 4U^2}}{2U}$$

By Equation (3) shows that: $|K| \le 1$, so:

$$K = \frac{-(V-W) + \sqrt{(V-W)^2 + 4U^2}}{2U} \tag{6}$$

2 Demodulation algorithm

PCM / FM signal is generated by two different frequencies to transmit information symbols. Therefore, the transition time is bound to two different symbols mutation frequency occurs, the frequency of the mutation point is also code synchronization position. Can be used instantaneous frequency measurement method by calculating the PCM / FM signal in continuous time sampling frequency, the frequency of mutations in the capture point, to achieve code synchronization.

Since actually received PCM / FM signal to the Doppler frequency shift, to improve the accuracy of code synchronization and demodulation performance in the demodulation process also requires the use of instantaneous frequency measurement method, Doppler frequency shift compensation, frequency measurement was corrected to "0" bit and the "1" code corresponding frequency. Doppler shift compensation from below, code synchronization and sentencing three aspects discussed in detail.

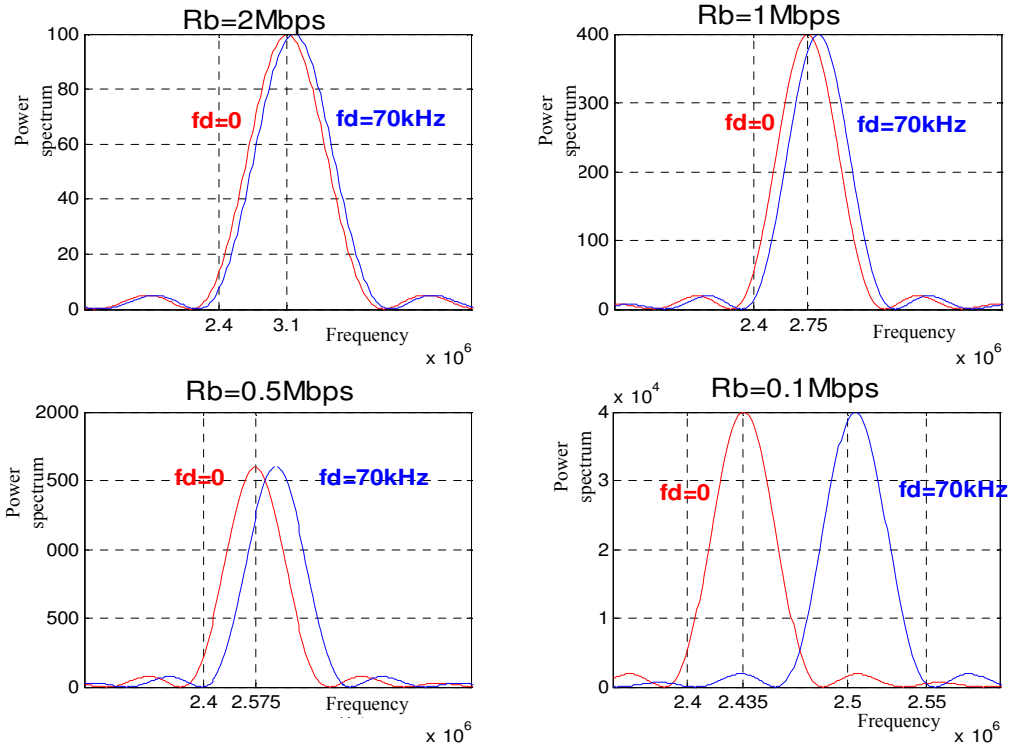

Fig1 Doppler frequency shift of the spectrum peak

Instantaneous Frequency Measurement Based on core PCM / FM demodulation method is that the instantaneous frequency of each symbol in accurate estimates and judgments. Received PCM / FM signal is always the Doppler frequency, this is reflected in the Doppler frequency PCM / FM signal carrier center frequency drift. Doppler positive bias 70KHz, different code rates, the "1" bit

corresponding to the frequency position, for example, analysis of the Doppler frequency shift of the maximum output position of the spectrum. The simulation results shown in Figure 1.

Can be drawn from Figure 1, the spectral Doppler shift effect on the maximum position with decreasing code rate is getting worse. Therefore, to reduce the error rates before demodulating the Doppler shift must be compensated.

The maximum instantaneous frequency corresponds to a "1" f_1 code of the actual frequency, minimum corresponds to the "0" code of the actual frequency f_0. Equation (8), (9) can be obtained after averaging the sum of:

$$\frac{f_1 + f_0}{2} = f_c + f_d \tag{10}$$

According to the Doppler frequency obtained corrected instantaneous frequency measurement results in "0" key and the "1" code corresponding frequency, thus avoiding the carrier frequency drift caused due demodulation error.

Receiving the synchronization accuracy of the transmission data in a data communication system is established on the basis of the correct synchronization. The hardware circuit is extracted synchronization code PLL core software demodulation code synchronization for the extraction process is the substance of each symbol, an optimal extraction processing start position starts from that position demodulating that demodulates achieve optimal performance.

Best code synchronization point PCM / FM signal is "0" key and the "1" code corresponding frequency hopping point. Instantaneous frequency measurement method, set a width (should be less than the width of a symbol sampling points) sliding window, calculate PCM / FM signal instantaneous frequency point by point, to capture the signal frequency hopping point, thus achieve code synchronization.

3 Performance Analysis

Instantaneous frequency measurement method throughout the demodulation process, including the estimated Doppler frequency and location code synchronization point, so instantaneous frequency measurement accuracy will directly affect the demodulation performance. Note that when you raise the following two aspects instantaneous frequency measurement accuracy:

1, the application frequency calculated instantaneous frequency measurement method is a prerequisite: the sampling signal is detected for a single carrier frequency, pure sinusoidal signal of constant amplitude, and does not contain a DC component.

2, the main parameters of the algorithm to the data window length, when selecting from two aspects: (1) Equation (6) actually uses the best approximation method, the more sampling points (ie the greater) for linear approximation, the better, the smaller the frequency measurement error.

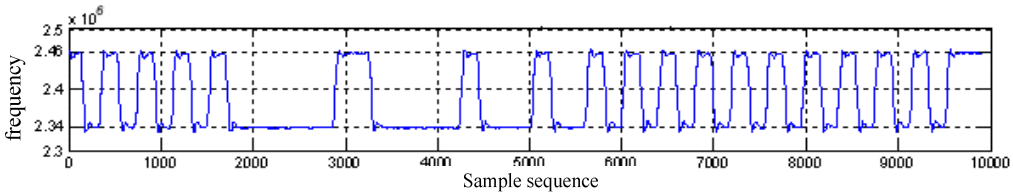

Fig2 PCM / FM signal instantaneous frequency measurement results

Can be clearly seen from Figure 2, since the waveform is similar to a rectangular pulse, when the decision threshold value for the carrier frequency, the positioning can be more accurate code synchronization point, to ensure the correctness of the demodulated result.

Figure 3 shows a comparison chart BER curves in the time code rate of 1.5Mbps. Demodulation performance can be seen that the method is relatively close to non-coherent demodulation performance under ideal conditions.

4 Summary

Instantaneous frequency measurement method for software demodulation PCM / FM signal can be corrected PCM / FM signal Doppler frequency shift caused by the carrier frequency, the more accurate the best position to extract the code synchronization is relatively simple to achieve demodulation symbol decision.

LFM Signal Detection Method Based on Fractional Fourier Transform

Wu Yanjun[1, a], Fu Gang[1,a] and Zhu Yuming[1,a]

[1]China Satellite Maritime Tracking and Control Department, China

[a]348237548@sina.com

Keywords: Time-frequency analysis, fractional Fourier transform (FRFT), discrete fractional Fourier transform (DFRFT), LFM signal

Abstract. As a generalization of Fourier transform, the fractional Fourier Transform (FRFT) contains simultaneity the time-frequency information of the signal, and it is considered a new tool for time-frequency analysis. This paper discusses some steps of FRFT in signal detection based on the decomposition of FRFT. With the help of the property that a LFM signal can produce a strong impulse in the FRFT domain, the signal can be detected conveniently. Experimental analysis shows that the proposed method is effective in detecting LFM signals.

Introduction

Fourier transform plays an important role in the continuous-time and discrete-time signal processing, analysis and processing is a powerful tool for stationary signals.[1] Fourier transform signal decomposition whole sinusoidal components having different frequencies get the whole spectrum of the signal, while the non-stationary signal processing becomes powerless.[2]

FRFT is a recently developed new time-frequency analysis tool, it is a generalized form of the Fourier transform, with many traditional Fourier transform are not available in nature, has been widely used in optical signal processing, signal analysis, differential equations, pattern recognition and other fields. Recent studies estimate and testing and other aspects of LFM signals based FRFT has been rapid development.

1 Radon-Wigner transform

Radon-Wigner transform is a linear integral projection transformation, is a signal of the Wigner-Ville distribution frequency plane straight line projection Randon integral transformation. As shown in figure 1, the time-frequency plane (t,ω) coordinate rotation angle α obtained a new Cartesian (u,v), with different values of u parallel to the v axis integral, Radon transformation result is obtained. (t,ω) and (u,v) are the coordinates of the relationship between the two planes is shown in formula (1).

$$\begin{cases} t = u\cos\alpha - v\sin\alpha \\ \omega = u\sin\alpha + v\cos\alpha \end{cases} \tag{1}$$

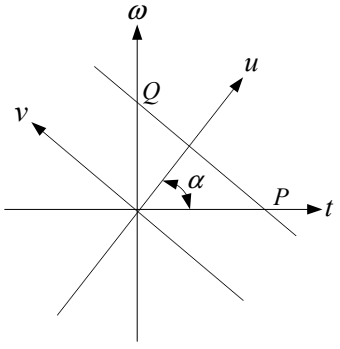

Fig 1 The geometrical explanations of Radon transform

Suppose an arbitrary two-dimensional function $f(t,\omega)$ on a plane (t,ω), which Radon transformation may be expressed as

$$P_\alpha(u) = \int_{PQ} f(t,\omega)dv \tag{2}$$

That is

$$P_\alpha(u) = \int_{PQ} f(u\cos\alpha - v\sin\alpha, u\sin\alpha + v\cos\alpha)dv \tag{3}$$

2 The definition of FRFT

Fourier transform is the time domain and frequency domain together; it shows the frequency components of the signal from the whole, it is suitable for stationary signal analysis and deterministic signals. For non-stationary signal frequency analysis, time-domain signal mapping it one-dimensional two-dimensional time-frequency plane, fully reflect the frequency distribution of the signal changes with time. Fourier transform as a linear operator, if it is seen from the perspective of a counterclockwise rotation $\pi/2$ to the frequency axis, the FRFT operator that can be rotated to any angle α of the operator. So combining Fourier Transform and Radon-Wigner transformation can be defined FRFT.[3]

p th order FRFT of signal $f(u)$ is defined as

$$f_p(u) = \int_{-\infty}^{+\infty} K_p(u,t) f(t)dt \tag{4}$$

Where the transform kernel function in Formula (4) is

$$K_p(u,t) = \begin{cases} A_\alpha \exp[j\pi(u^2\cot\alpha - 2ut\csc\alpha + t^2\cot\alpha)], & \alpha \neq n\pi \\ \delta(u-t), & \alpha = 2n\pi \\ \delta(u+t), & \alpha = (2n\pm 1)\pi \end{cases} \tag{5}$$

In formula (5), there is

$$A_\alpha = \frac{\exp[-j\pi\,\mathrm{sgn}(\sin\alpha)/4 + j\alpha/2]}{|\sin\alpha|^{1/2}},\ \alpha = \frac{p\pi}{2} \tag{6}$$

When the FRFT order $p=1$, there is $\alpha = \pi/2$ and $A_\alpha = 1$, then, according to equation (4), we can get

$$f_1(u) = \int_{-\infty}^{+\infty} e^{-j2\pi ut} f(t)dt \tag{7}$$

Therefore, $f_1(u)$ is the common Fourier transform of $f(t)$. Likewise, $f_{-1}(u)$ is an inverse Fourier transform of $f(u)$. Thus, it is considered that the fractional Fourier transform is a generalized Fourier transform. Because the kernel function $\alpha = \pi/2$, $\alpha_1 = p_1\pi/2$ only in the parameter of the trigonometric functions, so the cycle of the definition according to parameter p, therefore, we just need to examine the range $p \in (-2,2]$. When $p=0$, $f_0(u) = f(u)$, and when $p = \pm 2$, $f_{\pm 2} = f(-u)$.

3 DFRFT decomposition algorithm

In signal processing, we must adopt a discrete form of fractional Fourier transform (DFRFT), DFRFT can also be calculated using digital methods, commonly used algorithm is fast algorithm H.M.Ozaktas decomposition type proposed. The method is based on the so-called decomposition type FRFT expression, the FRFT decomposed into convolution signal, thus using FFT to calculate FRFT. The algorithm calculates the speed and the speed of FFT calculation rather, is a method of calculating the FRFT fast numerical methods. FRFT transformation matrix decomposition type as follows:

$$\mathbf{F}_p = \mathbf{D}\mathbf{K}_p\mathbf{J} \tag{8}$$

In formula (8), $\mathbf{D}$ and $\mathbf{J}$ is matrix of twice interpolation and decimation calculation respectively, $\mathbf{K}_p$ is transform kernel matrix of DFRFT, and its expression is:

$$K_p = \frac{A_\alpha}{2\Delta x}\exp[\frac{j\pi(\cot\alpha)m^2}{(2\Delta x)^2} - \frac{j2\pi(\csc\alpha)mn}{(2\Delta x)^2} + \frac{j2\pi(\cot\alpha)n^2}{(2\Delta x)^2}]|m||n| \le N \tag{9}$$

After one-dimensional normalized, the definition of DFRFT is

$$X_p(u) = \sqrt{\frac{1-j\cot\alpha}{2\pi}}\exp[j\pi\cot(\alpha)u^2]\int_{-\infty}^{+\infty} x(t)\exp[j\pi\cot(\alpha)t^2]\exp[-j2\pi\csc(\alpha)tu]dt \tag{10}$$

Do a discrediting processing to Equation (9) in FRFT domain u, we can obtain:

$$X_p(\frac{m}{2\Delta x}) = \frac{A_\alpha}{2\Delta x}\sum_{n=-N}^{N}\exp[\frac{j\pi(\cot\alpha)m^2}{(2\Delta x)^2} - \frac{j2\pi(\csc\alpha)mn}{(2\Delta x)^2} + \frac{j\pi(\cot\alpha)n^2}{(2\Delta x)^2}]x(\frac{n}{2\Delta x})$$

$$= \frac{A_\alpha}{2\Delta x}\exp[\frac{-j\pi\tan(\frac{\alpha}{2})m^2}{(2\Delta x)^2}]\times\sum_{n=-N}^{N}\exp[\frac{-j\pi(\csc\alpha)(m-n)^2}{(2\Delta x)^2}]\times\exp[\frac{-j\pi\tan(\frac{\alpha}{2})n^2}{(2\Delta x)^2}]x(\frac{n}{2\Delta x}) \tag{11}$$

Where $A_\alpha = \exp\left[j(p-1)\frac{\pi}{4}\right]/\sqrt{|\sin\alpha|}$, $0.5 \le p \le 1.5$, $\alpha = \frac{p\pi}{2}$, $N = (\Delta x)^2$.

The operation of sum can be seen as the convolution operation of two sequences $\exp[\frac{j\pi(\csc\alpha)n^2}{(2\Delta x)2}]$ and $\exp[\frac{-j\pi\tan(\frac{\pi}{2})n^2}{(2\Delta x)^2}]x(\frac{n}{2\Delta x})$.

4 Detection theory of LFM signal based on FRFT

The inverse FRFT expression can be written as

$$x(t) = \int_{-\infty}^{+\infty} X_p(u)K_{-p}(t,u)du \tag{12}$$

We can know that the FRFT can be seen as a signal $x(t)$ on a nuclear base in the inverse transform function $K_{-p}(t,u)$ space expansion, and the kernel function is a set of orthogonal chirp base on the domain u. Therefore, LFM signal at the appropriate FRFT domain will be expressed as a function of the impact that a certain order of FRFT FRFT domain of LFM signal given with good energy aggregation characteristics. The aggregation feature is the theoretical basis of FRFT LFM signal detection.

In one aspect, Wigner distribution of the signal at FRFT domain linear integral projection is that the signal on this domain FRFT Fractional square norm. If you find FRFT signals on a straight line perpendicular to the inclined fractional domain, obvious peak appears at a certain point the domain. And the noise energy is uniformly distributed throughout the time-frequency plane, in any domain FRFT energy concentration will not occur.

On the other hand, LFM signal on a different FRFT domains exhibit different characteristics of energy gathering, testing LFM signal containing location parameters is carried FRFT rotation angle α scanning, observing the signal, the signal energy in the form parameters (α,u) two-dimensional distribution of the plane, on this plane to the peak point of the two-dimensional search LFM signal detection and estimation of its parameters.

5 Simulation results

In FRFT domains, in their presentation accordingly chirp rate at the maximum, by simple thresholding, we can detect the existence of LFM signal and FM slope parameter estimates when rendered in accordance with the order corresponding to the maximum on FRFT.

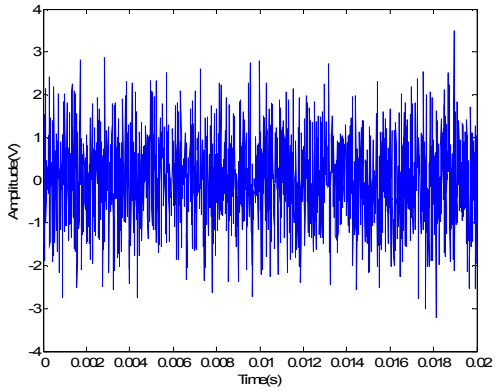

Fig2 Waveform of white Gaussian noise in time domain

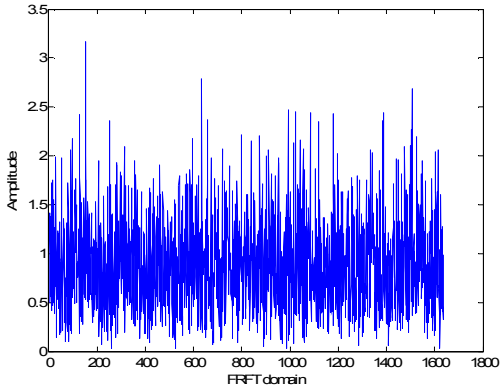

Fig3 Waveform of white Gaussian noise in FRFT domain

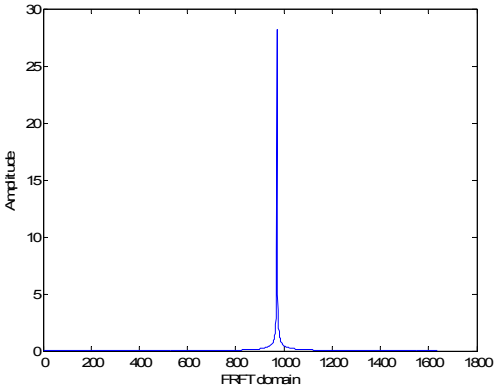

Fig4 Waveform of LFM signal in time domain

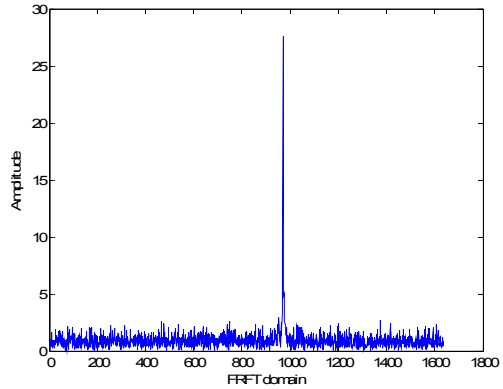

Fig5 The polluted LFM signal in FRFT domain

According to the four figure above, we can find that the waveform of white noise in FRFT domain still be noise wave and it cannot gather energy in any FRFT domain. Further more, the noise cannot influence the energy concentration of LFM signal in its best FRFT domain, and it is critical factor for LFM signal detection and parameter estimation in FRFT domain.

Summary

FRFT can be regarded as showing FRFT FRFT frequency domain signal after the plane at any angle of rotation about the origin constituted on the FRFT decomposed signal using FFT convolution calculation has the advantage of fast calculation. LFM signal with a non-stationary, stationary signal processing using methods often can not be satisfied with the results. Since the LFM signal FRFT domain impulse characteristics presented when the order chirp rate FRFT consistent with the LFM signal, the signal showing spikes, in order to achieve detection of LFM signal. Experimental results show that the signal detection method based on the LFM signal FRFT whether the noise can be satisfied with the results.

Interference Suppression of VLF Communications in Atmospheric Noise

Wu Yanjun[1, a], Fu Gang[1,a] and Geng Wenjian[1,a]
[1]China Satellite Maritime Tracking and Control Department, China
[a]348237548@sina.com

Keywords: VLF Communication, FRFT, Chirp Spread Spectrum (CSS), Interference Suppression, Clipping

Abstract. This paper focuses on the weak signal reception and atmospheric noise suppression in VLF Chirp spread spectrum communication system. Due to interference of atmospheric noise generated by lightning phenomena, it makes the chirp signal detection under low SNR condition becoming more difficult. Therefore, we select alpha stable distribution noise model to generate noise to simulate the real atmospheric noise. Then, we introduced a new technique of Chirp Spread Spectrum (CSS) communication based on Fractional Fourier Transform (FRFT). Finally, we study a nonlinear processing interference suppression method of clipping in time domain. Simulation results verified its feasibility.

Introduction

VLF communication channel is with severe interference, narrow band, low antenna radiation efficiency and power-constrained characteristic. The Atmospheric noise generated by lightning phenomena is the main sources of interference in VLF communication, the receiving weak communicating signal is not only submerged by the strong background completely, but also jammed by atmospheric noise generated by lighting phenomenon and make it very difficult to detect communication signals under a low SNR condition. Thus, it is so necessary to study a new interference suppression method in VLF communication.

In the field of signal processing, Fourier transform is treating as a linear operator describes the characteristics of the signal in the frequency domain, if we think the Fourier transform as rotating angle from the axis to the frequency axis, the FRFT can be understood at any angle of rotation operator. Thus, we can get a new representation form of signal in a new domain and characteristics of the signal will also be reflected in the new axis. Therefore, FRFT is a uniform frequency conversion in essence. In addition, FRFT is a generalized Fourier transform, while retaining all the properties of the Fourier transform, the FRFT also has some new features.

1 Fractional Fourier transform (FRFT)

FRFT is defined as:

$$X_p(u) = \left\{\mathcal{F}^p[x(t)]\right\}(u) = \int_{-\infty}^{+\infty} K_p(u,t)x(t)dt \tag{1}$$

Where, the transform kernel function $K_p(u,t)$ is

$$K_p(u,t)=\begin{cases}\sqrt{\dfrac{1-j\cot\alpha}{2\pi}}\exp(A) & \alpha \neq n\pi \\ \delta(t-u) & \alpha=2n\pi \\ \delta(t+u) & \alpha=(2n\pm 1)\pi\end{cases} \tag{2}$$

Where $A = j\cdot\dfrac{(t^2+u^2)}{2}\cdot\cot\alpha - jut\csc(\alpha)$, $\alpha = p\pi/2$ represents the rotation angle of the transformed signal for pth FRFT.

According to formula (1), we can easily getting the inverse FRFT expression as

$$x(t) = \mathcal{F}^{-p}\left[X_p\right](t) = \int_{-\infty}^{+\infty} X_p(u) K_{-p}(t,u)du \tag{3}$$

So far, a lot of fast algorithms of FRFT were put forward to calculate discrete FRFT. Due to its low complexity and high precision, we select the fast algorithm of discrete FRFT presented by H.M.Ozaktas[1][2] to compute the discrete FRFT in this paper.

2 Chirp spread spectrum theory

A. Modulation

In this section, we study a binary orthogonal keying (BOK) communication system. The system communicates with others through using chirp rate of a Chirp signal to carry binary code information. The CSS communication system uses different chirp rate of chirp signal to modulation binary code, and it means code '1' is denoted by chirp signal with a positive number chirp rate μ ($\mu > 0$), and it is called up-chirp signal. Analogously, the chirp signals with negative number chirp rate $-\mu$ is called down-chirp signal, and it represents code'0'. Figure 1 shows theory of CSS modulator.

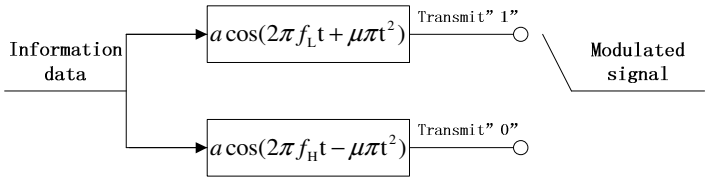

Fig1 The theory of chirp rate modulation

Where T , a , μ , f_L and f_H represent chirp duration, envelop, chirp rate, initial frequency and top frequency respectively, and $B=f_H - f_L = \mu T$ represents bandwidth of chirp signal [3].

B. FRFT Demodulation

According to formula (3), we known that chirp signal with specified chirp rate will gather energy concentration in a special FRFT domain, and when the transform order varies from 0 to 2, there is a one-to-one relationship between chirp rate and transform order as

$$\mu = -\cot(\alpha) \tag{4}$$

The transmitted Chirp signals are in forming of cosine function in CSS communication system. It can be divided into sum of a up-chirp signal and a down-chirp signal as follow

$$s(t) = a\cos(2\pi f_0 t + \pi\mu t^2) = \frac{a(e^{j(2\pi f_0 t + \pi\mu t^2)} + e^{j(-2\pi f_0 t - \pi\mu t^2)})}{2} \tag{5}$$

Therefore, we can deduce that up-chirp and down-Chirp signal gather energy in the same FRFT domain according formula (5), but the position of peak in FRFT domain is different. The wave form of up-chirp and down-chirp signal in FRFT domain as follow

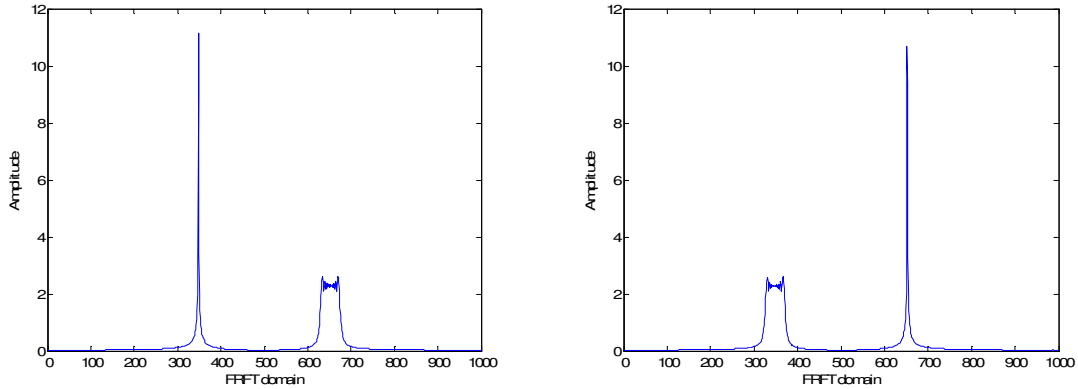

Fig2 Wave form of code "0"and"1"in p th FRFT domain

Observing the waveform of Up-chirp and Down-chirp signal in best FRFT domain, we can demodulate binary code according to peak position of chirp signal in FRFT domain. Figure 3 shows the diagram block of FRFT demodulation [4].

3 Clipping method

The transmitting VLF electromagnetic waves reaches receiver after a long-distance transmission is belonging to “weak signal" usually. This "weak signal" is not only means that the signal amplitude is low, but strong background noise and high amplitude impulse interference caused by the thundering near the receiver, and it makes the receiving signal low SNR. Therefore, in order to improve weak signal reception in VLF communication system, we need to find an effective weak signal detection and atmospheric noise suppression method.

In this section, we take advantage of Chirp Spread Spectrum communication in VLF communication system, demodulating binary code in FRFT domain, and it also suppresses atmospheric noise interference in a certain extent. In order to weaken atmospheric noise interference ulteriorly, we set a clipper in front of receiver according to the time-domain characteristics of atmospheric noise, and do nonlinear clipping to received signal and weaken high level spikes to improve reliability of receiver. Figure 3 shows character of clipper.

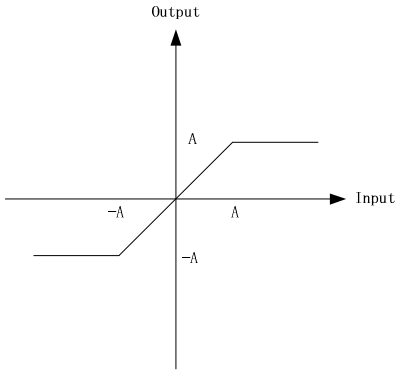

Fig3 The clipping input and output characteristic curve

According to Figure 3, it shows the received VLF signal after clipping is

$$s'(t)=\begin{cases} A, & s(t)\geq A \\ s(t), & -A<s(t)<A \\ -A, & s(t)\leq -A \end{cases} \tag{6}$$

4 Performance analyses

In this section, we simulate the performance of Chirp spread spectrum system in condition of interference suppression.[3][4] We treat alpha stable distribution noise model as the actual atmospheric noise model, and select symmetrical alpha stable distribution to generate atmospheric noise which is near the receiver. Due to inexistence of two rank squares in symmetrical alpha stable distribution, so, we set the SNR instead by mixture SNR, it is called signal to interference ratio and defined as follow

$$MSNR_{dB}=10\log_{10}(P_s/\sigma) \tag{7}$$

Where P_s is power of receiving chirp signal, σ is scale parameter of symmetrical alpha stable distribution.

The simulation parameter is set as: sample rate $f_s=81.92kHz$, central frequency of Chirp signal $f_0=7.6kHz$, bandwidth $B=1.2kHz$, code rate $R_b=50bps$, spread spectrum gain $G_p=13.8dB$.

Additionally, character parameters of symmetrical alpha stable distribution is set as $\alpha = 1.8$, scale parameter $\sigma = 1$, location parameter $\mu = 0$, and the mixture signal to noise ration is $MSNR = 0$ dB.

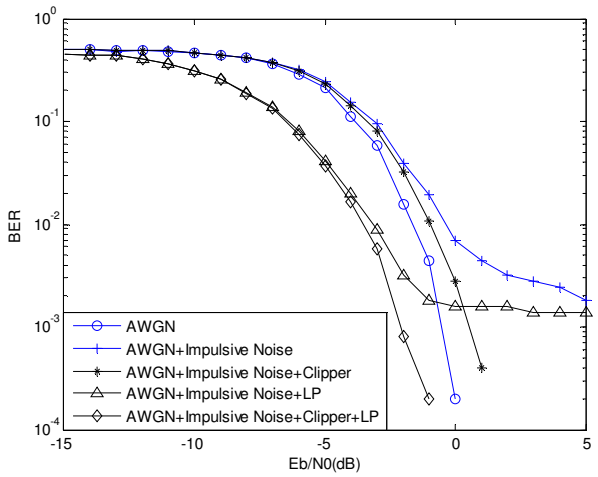

Fig4 VLF CSS System performance in clipper and low-pass filter

Where AWGN, Impulsive noise, Clipper is representing as environment of CSS system respectively.

According figure 4, we can easily know that the BER performance of low-pass filtering after clipping is better than the BER performance in AWGN. Further more, no matter what the SNR are, the performance of clipping after low-pass filtering has big improvement comparing with the BER performance in impulsive noise.

Summary

In this paper, we introduced theory of FRFT and technique of Chirp spread spectrum communication firstly, and then analysis the nonlinear time domain clipping algorithm of atmospheric noise interference suppression, the simulation results proved the nice performance of atmospheric noise interference suppression method. The conclusion in this paper is a useful method of VLF atmospheric noise interference suppression and it can play an important role in VLF communication.

Keywords: Adaptive radar, FrFT, STFT, Joint time-frequency analysis.

Abstract. Faced with complex electromagnetic environment and varieties of adaptive radar waveforms, radar signal analysis and identification becomes more and more complex. Considering two important physical quantities - time and frequency in modern signal processing methods, this paper proposes that the joint time-frequency analysis (JTFA) method based on fractional Fourier transform (FrFT) and short-time Fourier transform (STFT) is applied to adaptive radar signal processing. The simulation results show that the joint time-frequency analysis method is superior to single short-time Fourier transform, getting a better analysis of results. The joint time-frequency analysis method provides the joint distribution of the time domain and frequency domain for adaptive radar signal analysis and describes the relationship between signal frequency and time.

1 Introduction

In 1960s and 1970s, the radar technology develops rapidly and a variety of new radars emerge in that period, such as synthetic aperture radar, pulse Doppler radar, phased array radar etc.[1]. In the new century, with the situation of various goals, complex environment and diverse tasks, people require performance of radar higher and higher [2] Meanwhile, the radars are faced with challenges of integrated interference, anti-radiation missiles, stealth technology and low altitude penetration [3]. Adaptive radar arises under this kind of background.

The so-called adaptive radar means that it can rapidly changes relevant parameters automatically, adjusting to the optimum working condition following the changes in the environment. Such radars usually use an adaptive antenna array [4]. Adaptive radar, with good anti-jamming capability, can automatically identify, judge, choose and track the target in the time domain and frequency domain. Adaptive radar does not refer to a particular radar, but a certain type of radar. They all belong to adaptive radar providing that they meet the definition of adaptive radar scope, such as phased array radar with adaptive beam-forming, digital array radar[5], software radar[6] and cognitive radar[7]. Phased array radar is a prototype of the adaptive radar, while the cognitive radar is the result of a higher level of the development of adaptive radar. Matching process of transmitter and receiver of adaptive radar with environment can greatly improve the performance of the radar.

Adaptive radars are usually multifunction radars. To adapt the complex electromagnetic environment and meet the requirements of different functions, the waveform design is complex and diverse, which makes it difficult for signal analysis and identification. In modern signal processing methods, time and frequency are two important physical quantities, and the relationship between time domain and frequency domain is closely. In the feature extraction process of the signal, combine the frequency domain characteristics if it can't obtain a good signal characteristic in the time domain. This tends to get a better effect. Time-frequency analysis method provides a joint distribution of the time domain and frequency domain for adaptive radar signal analysis, describing the relationships between signal frequency and time. In [8],Wang Xiaohua presents the radar signal intra-pulse analysis method based on FrFT and STFT, analyzing and simulating the chirp radar pulse signal.

Parameters of adaptive radar signals mainly include amplitude, phase, frequency, pulse width and so on. The radar pulse features are usually analyzed according to the pulse modulation type and the pulse modulation parameters. The radar signal is identified by extracting and separating these distributions and changes, and then the radar system, property and nature of the threat. This paper presents that JTFA is applied to adaptive radar signal processing, mainly studying four kinds of radar pulse signal, and the simulation results are given finally.

2 Principle of JTFA

Joint time-frequency analysis refers to the signal to go through fractional Fourier transform and then short-time Fourier transform, improving the resolution of the short-time Fourier analysis by adjusting the angle of rotation. It makes energy more concentrated and can effectively analyze the subtle characteristics of the signal.

2.1 Principle of FrFT

Fractional Fourier transform is a new time-frequency tool. It is the generalized form of the classical Fourier transform. Fractional Fourier transform is a signal representation method when the signal in the time-frequency axis in the plane rotates any angle around the origin counterclockwise. When the rotation angle is $\pi/2$, it is the traditional Fourier transform[9]. The fractional Fourier transform of signal $s(t)$ is defined as follows:

$$X_p(u) = F^p[s(t)](u) = \int_{-\infty}^{+\infty} s(t) K_p(u,t)\,dt \tag{1}$$

$$K_p(u,t) = \begin{cases} \sqrt{\dfrac{1-j\cot\alpha}{2\pi}} \exp\left[j\left(\dfrac{t^2+u^2}{2}\right)\cot\alpha - jut\csc\alpha\right] & \alpha \neq n\pi \\ \delta(t-u) & \alpha = 2n\pi \\ \delta(t+u) & \alpha = 2n\pi \pm \pi \end{cases} \tag{2}$$

α is the rotation angle, ie the angle between the fractional Fourier domain and time domain. The rotation angle $\alpha = p\pi/2$, p is the order of fractional Fourier transform. When $p=1$, it is the classical Fourier transform. Its rotational axis coordinate system shows in Figure 1. $F^p[]$ is the fractional Fourier transform operator, $K_p(u,t)$ is the transformation kernel, n is an integer, $\delta(\bullet)$ is the impulse function. The purpose of introducing the conversion axis coordinate system is to get the best signal time-frequency representation.

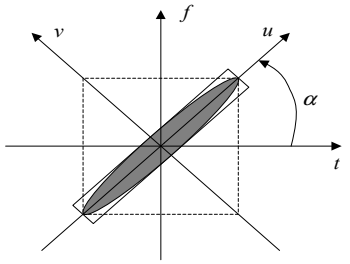

Figure1 Time-frequency plane rotation angle α coordinate

Figure 1 shows: $X_0 = s(\mu)$, $X_2(\mu) = s(-\mu)$, $X_1(\mu)$ corresponds to the classical Fourier transform of signal. Its rotational relationship is:

$$\begin{bmatrix} \mu \\ v \end{bmatrix} = \begin{bmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{bmatrix} \begin{bmatrix} t \\ f \end{bmatrix} \tag{3}$$

FrFT is more flexibility compared to the traditional Fourier transform, suitable for processing non-stationary signals. Many properties of FrFT on the theoretical study are of great significance. When $\alpha \neq n\pi$, the calculation process can be broken down into the following four steps:

(1) The original signal is multiplied with a chirp function:

$$s0(t) = s(t)e^{-j\pi t^2 \cot\alpha} \tag{4}$$

(2) Do the Fourier transform:

$$s'0_\alpha(t) = \int_{-\infty}^{+\infty} s0(t)e^{-j2\pi ut \csc\alpha} dt \tag{5}$$

(3) Multiplied with a chirp function:

$$X'_p(u) = s'0_\alpha(t)e^{-j\pi u^2 \cot\alpha} \tag{6}$$

(4) Multiplied by complex amplitude factor:

$$X_p(u) = \sqrt{\frac{1-j\cot\alpha}{2\pi}} X'_p(u) \tag{7}$$

In the above definition, although p can be taken any real number, periods of the fractional Fourier transform is 4. So it is usually consider only in [0, 4].

2.2 Principle of STFT

The basic idea of short-time Fourier transform is that in the framework of the traditional Fourier transform, the non-stationary signals are viewed as superposition of a series of short-time stationary signal. Short of the time is achieved by adding windows and cover the entire domain by translating parameters. For a given non-stationary signals, $s(t) \in L^2(R)$, short time Fourier transform of signal $s(t)$ is defined as:

$$STFT_s(t,\omega) = \int_{-\infty}^{+\infty} s(\tau)h(\tau - t)e^{-j\omega\tau} d\tau \tag{8}$$

In general, $h(t)$ is the real function and its energy of Fourier transform concentrated in the low frequency. It can be viewed as the impulse response of a low-pass filter. As can be seen from the definition of formula, the signal $s(t)$ is divided by adding window functions $h(t)$ by translating parameter t:

$$s_t(\tau) = s(\tau)h(\tau - t) \tag{9}$$

Do Fourier transform for the signal $s_t(\tau)$ on the basis of obtaining signal in interval τ of original signal which is in near time t. With the changes of the translation parameters, time window determined by $h(t)$ moves on the timeline, so that the signal gradually go into the state to be analyzed. Since the segment signal $s_t(\tau)$ shows characteristics of the interval t of the original signal, so the Fourier transform of the segment signal reflects the frequency distribution of the original signal at the interval. Its advantage is simple and easy to implement the algorithm, the processing time is short and suitable for time-frequency of all non-stationary signal.

2.3 Principle of JTFA

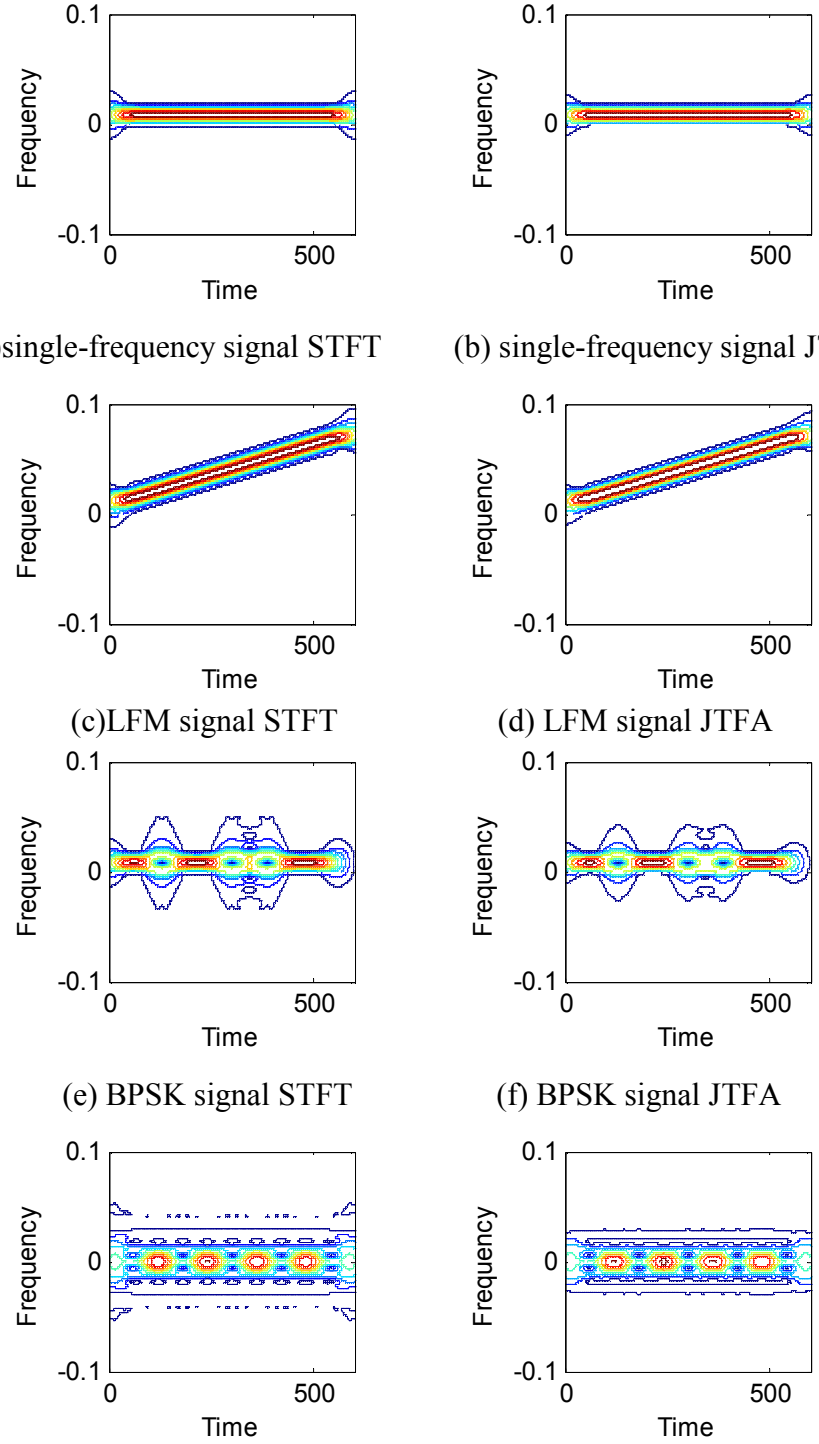
Since the fractional Fourier transform can be rotated any angle compared to Fourier transform, it can improve the resolution of short-time Fourier transform on the basis of fractional Fourier transform. Joint -time Fourier transform is defined as:

$$\begin{aligned} STFT_s^\alpha(\mu,\nu) &= STFT_{X_p}(\mu,\nu) \\ &= \int_{-\infty}^{+\infty} X_p(\tau)h(\tau - \mu)e^{-j\omega\tau} d\tau \end{aligned} \tag{10}$$

$STFT_s^\alpha(\mu,\nu)$ calculations can be seen as general short-time Fourier transform of signal $s(t)$. The initial window uses the fractional Fourier transform. If the STFT window is too narrow, the resolution will be decreased in frequency domain; if the window is too wide, the resolution will decrease in time domain. Time domain and frequency domain can't get both high resolution simultaneously. The joint time-Frequency analysis enables the energy more concentrated in time-frequency domain. Selecting the appropriate angle of rotation can get the best time-frequency representation, meanwhile, this method is not affected by cross term interference, solving the problem that the resolution of single short-time Fourier transform is low.

3 Simulation

Signal forms of adaptive radar are various, and its waveforms are complex. According to the radar function, the waveform is usually designed on the basis of characteristics of the ambiguity function. Ambiguity function is mainly divided into four categories. The paper selected four kinds of signals according to ambiguity function, namely, single-frequency signal, LFM signal, BPSK signals and coherent pulse-sequence signal. Ambiguity function of these four kinds of signals represents four types of ambiguity function. Simulation of the joint time-frequency analysis is shown in Figure 2.



(a)single-frequency signal STFT (b) single-frequency signal JTFA

(c)LFM signal STFT (d) LFM signal JTFA

(e) BPSK signal STFT (f) BPSK signal JTFA

(g) coherent pulse-sequence signal STFT (h) coherent pulse train signal JTFA

Figure 2 Comparison of Signal STFT and JTFA

Simulation environment: Microsoft Windows XP Professional 2002, CPU: 2.6GHz, HDD: 150G, Memory: 2G. The simulation tool is MATLABR2009b. Simulation signal: pulse width T=2us, carrier frequency fc=2.5e6Hz, sampling rate: 300MHz. LFM signal modulation factor k = 1e13, coherent pulse-sequence signal PRI=4us.

Figure 2 shows that the joint time-frequency analysis method do have a better result than single short-time Fourier transform in the radar pulse signal analysis process. Energy of the joint time-frequency analysis is more concentrated in certain areas, therefore, the joint time-frequency analysis method can be appropriate to cover defects of STFT. In addition, the order of FrFT p will affect the signal analysis results when the window function is for fractional Fourier transform. To get the best effect of time-frequency representation, the frequency axis should rotate a right angle.

4 Conclusion

This article applies the joint time-frequency analysis method to adaptive radar signal analysis. Simulation results show that the joint time-frequency analysis method is better than the single short time Fourier transform. The joint time-frequency analysis method can effectively analyze the time-frequency characteristic of radar signals and improve the analysis resolution. This distribution can be more accurately reflects the frequency of the signal changes over time.

Keywords: same-beam interferometry; related processing; integer ambiguity

Abstract. Same-beam interferometry (SBI) has a wide range of applications and prospects in collocate geostationary satellites, space rendezvous and docking, landers and rovers positioning. The paper introduces the basic principles, underlying processing algorithms, ambiguity resolution solving, process flow comprehensively and systematically. Then use FX-related processing algorithms and integer ambiguity solution method step by step to process signals, draw process flowchart.

Introduction

With the deepening of deep space exploration in our country, a variety of new interference measure technologies are widely used in precise orbit determination and control. Thanks to its high-precision, real-time, flexible distribution network, and low baseline length requirements, SBI is more excellent to be widely used.

For example, there had been already 1120 geosynchronous satellites in an about 60km wide area in 2005[1], hence the orbital resources are becoming more and more tense. Collocated satellites technology is used to solve this [2]. This technology requires multiple satellites in a relatively small space to run, increasing their risk of collision. In the space rendezvous and docking [3], the ground should simultaneously monitor and control two or more spacecraft, and complete several precise orbit control and forecasting in a very short time, then measure relative positions precisely. If you want a more direct and richer understanding of target stars, soft-landing detection, patrolling and plumbing detection is essential. The precise measurements of the relative position of rovers and landers are important. In conclusion, we need to solve problems above. SBI can achieve high accuracy and relative position measurements accuracy can achieve within 10m with short baseline [4], and provide important complements and enhances of ground-based Doppler measurements, distance measurements of sight information and other control instruments.

SBI had already begun to be used in the detection of deep space in the 1970s in foreign countries, been listed as key development projects [5].Domestic research and applications should further improve and enhance. This paper introduces the principle, related processing algorithms, integer ambiguity solution, and process flow.

The Principles

When the two spacecraft in perspective are very close, you can use two antennas of two different ground stations to observe two spacecraft simultaneously in a beam, and get their dual differential interferometry volume. Then obtain high-precision relative distance information about two spacecraft in air plane. As shown in Fig. 1.

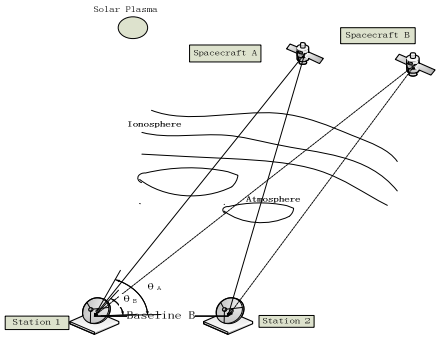

Fig. 1 SBI schematic diagram

SBI observation systems typically include two stations (station 1,2), two spacecraft (spacecraft A , B), and multi-frequency signals (typically more than three frequencies) [6].The station 1,2 receiving delay from spacecraft A,B:

$\tau_{ob_A1} = \tau_{g_A1} + \tau_{c1} + \tau_{s_A1} + \tau_{e_A1}$, $\tau_{ob_A2} = \tau_{g_A2} + \tau_{c2} + \tau_{s_A2} + \tau_{e_A2}$

Here: τ_g is the theoretical delay; τ_c the clock error between spacecraft and station; τ_s is the propagation delay introduced by atmospheric, plasma and other media; τ_e is device delay .The spacecraft B delay that the station 1， 2 receive are likewise:

$\tau_{ob_B1} = \tau_{g_B1} + \tau_{c1} + \tau_{s_B1} + \tau_{e_B1}$, $\tau_{ob_B2} = \tau_{g_B2} + \tau_{c2} + \tau_{s_B2} + \tau_{e_B2}$

The delay inequality between station 1 and 2 receiving from spacecraft A and B are

$\Delta\tau_{A12} = (\tau_{g_A1} - \tau_{g_A2}) + (\tau_{c1} - \tau_{c2}) + (\tau_{s_A1} - \tau_{s_A2}) + (\tau_{e_A1} - \tau_{e_A2})$, $\Delta\tau_{B12} = (\tau_{g_B1} - \tau_{g_B2}) + (\tau_{c1} - \tau_{c2}) + (\tau_{s_B1} - \tau_{s_B2}) + (\tau_{e_B1} - \tau_{e_B2})$

When the angular distance of two spacecraft is very small, propagation media delay and equipment delay of each spacecraft between stations can be considered to be equal. that is $\tau_{s_A1} = \tau_{s_B1}$, $\tau_{s_A2} = \tau_{s_B2}$; $\tau_{e_A1} = \tau_{e_B1}$, $\tau_{e_A2} = \tau_{e_B2}$. so double different time delay is $\Delta\tau_{AB} = (\tau_{g_A1} - \tau_{g_A2}) - (\tau_{g_B1} - \tau_{g_B2})$ 。

When the effect of thermal noise is not considered, Double differential delay measurements at any corresponding frequency will be equal to the theoretical delay measurements, and independent of frequencies. When making double-difference calculation, a number of system errors are eliminated. After getting the double differential delay, we can get high-precision angle measurements of two spacecraft separation in sky plane. The formulas are:

$\frac{B\cos\theta_A}{c} = \tau_{ob_A1} - \tau_{ob_A2} = \Delta\tau_{A12}$, $\frac{B\cos\theta_B}{c} = \tau_{ob_B1} - \tau_{ob_B2} = \Delta\tau_{B12}$

Here B is the baseline length, θ_s is the angle (S = A, B), c is the speed of light.

Double differential delay $\Delta\tau_{AB}$ can be written as $\Delta\tau_{AB} = \frac{B\cos\theta_A}{c} - \frac{B\cos\theta_B}{c}$

The two spacecraft should can be seen in a beam during same-beam observation, so $\Delta\theta = \theta_A - \theta_b$ may be small enough to make $\theta_A \approx \theta_B$,and $\sin\left(\frac{\theta_A - \theta_B}{2}\right) = \frac{\Delta\theta}{2}$, $\sin\left(\frac{\theta_A + \theta_B}{2}\right) = \sin\theta_A$. Thus

$\Delta\tau_{AB} = \frac{B\sin\theta_A \cdot \Delta\theta}{c}$

Therefore, the angle measurement accuracy of spacecraft is $\Delta\theta = \frac{c\Delta\tau_{AB}}{B\sin\theta_A}$. The measurement accuracy in the spatial position of the spacecraft is $\Delta l = c\tau \cdot \Delta\theta$.

Processing Algorithms

The paper describes how to get the double differential delay observations. In terms of the station 2 as the reference, the RF reception signal can be expressed as: $x_{h1n} = \exp(j2\pi f_{hn}(t + \tau_{ob_hn}(t)))$ $x_{h2n} = \exp(j2\pi f_{hn} t)$

Due to the relative motion between the spacecraft and the station, the delay difference between stations is time-varying, can be written as:

$$\tau_{ob_hn}(t) = \tau_{ob_hn} + v_{ob_hn} + v_{h1}t$$

Theoretical delay rate is only related with relative motion between the spacecraft and the station, nothing to do with frequency, but after effects of the ionosphere, delay rate and frequency are related, this impact reflected in the Doppler frequency is only mHz, we do not consider the relationship between the delay rate and the frequency. Therefore:

$$\begin{aligned} x_{h1n} &= \exp\left(j2\pi f_{hn}\left(t + \tau_{ob_hn} + v_{h1}t\right)\right) \\ &= \exp\left(j2\pi\left(f_{hn} + f_{d_h1n}\right)t + j2\pi f_{hn}\tau_{ob_hn}\right) \end{aligned}$$

Here $f_{d_h1n} = f_{hn}v_{h1}$ is Doppler frequency .After down-conversion, the two stations receive signals are as follows:

$$x_{h1n} = \exp\left(j2\pi\left(f_{Ihn} + f_{d_h1n}\right)t + j2\pi f_{Ihn}\tau_{ob_hn}\right), \quad x_{h2n} = \exp\left(j2\pi f_{Ihn}t\right)$$

Here f_{Ihn} is IF frequency of f_{hn} .According to the priori delay model $\hat{\tau}_{ob_hn}$ and the priori Doppler frequency model $\hat{f}_{ob_hn}$, the signal of station 1 can do streak rotation and time-delay compensation:

$$\begin{aligned} & x_{h1n}\exp\left(-j2\pi\hat{f}_{d_h1n}t\right)\exp\left(-j2\pi\hat{f}_{Ihn}\hat{\tau}_{ob_hn}\right) \\ &= \exp\left(j2\pi\left(f_{Ihn} + \Delta f_{d_h1n}\right)t + j2\pi\hat{f}_{Ihn}\Delta\tau_{ob_hn}\right) \end{aligned}$$

Here $\Delta f_{d_h1n} = f_{d_h1n} - \hat{f}_{d_h1n}$; $\Delta\tau_{ob_hn} = \tau_{ob_hn} - \hat{\tau}_{ob_hn}$ .and $\Delta\nabla\hat{\tau} = \hat{\tau}_{ob_An} - \hat{\tau}_{ob_Bn}$.

There are generally FX type and XF type two related processing methods [7]. Here the signal will use the FX-type processing method to deal with [8], as shown in Fig. 2.

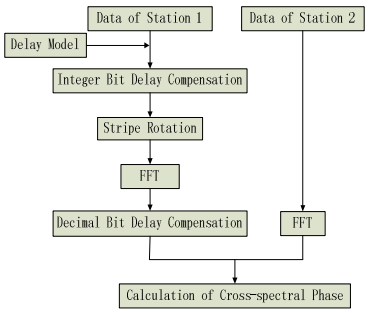

Fig. 2 FX type process's flow chart of SBI signals

The cross-spectral phases $\phi_{hn} = 2\pi f_{hn}\Delta\tau_{ob_hn} + 2\pi N_{hn}$ between stations can be obtained by FX-type processing method. N_{hn} is Integer Ambiguity. The cross-spectral phases make the difference. When the frequency resolution and reference station delay model error are small enough, you can get:

$$\phi_n = \phi_{An} - \phi_{Bn} = 2\pi f_{An}\Delta\tau_{ob_An} + 2\pi N_{An} - \left(2\pi f_{Bn}\Delta\tau_{ob_Bn} + 2\pi N_{Bn}\right) = 2\pi f_{An}\Delta\nabla\tilde{\tau} + 2\pi\Delta N_n$$

Here : $\Delta N_n = N_{An} - N_{Bn}$; $\Delta\nabla\tilde{\tau} = \Delta\nabla\tau - \Delta\nabla\hat{\tau} = \Delta\tau_{ob_An} - \Delta\tau_{ob_Bn}$ is remnant double differential delay.

If the integer ambiguity corresponding to a frequency is known and calculation accuracy of ϕ_n is equal, the double differential delay based on the highest frequency f_{A3} has the highest accuracy, expressed as follows:

$$\Delta\nabla\tau = \Delta\nabla\tilde{\tau} + \Delta\nabla\hat{\tau} = \frac{\phi_3 - 2\pi\Delta N_3}{2\pi f_{A3}} + \Delta\hat{\tau}_{ob_A3} - \Delta\hat{\tau}_{ob_B3}$$

Integer Ambiguity Solver

SBI Signals Processing Solutions can be implemented step by step. We can use group delay measurements to determine the ambiguity, and Japan's SELENE Program utilizes this method [9]. There are derivation steps and prerequisites as follows [10]:

As shown in Fig. 3, you can deduce $\Delta N_2 - \Delta N_1$ in a narrow 6 MHz band between f_{A1} and f_{A2} firstly. Referring the group delay of between f_{A1} and f_{A2}, adjust the integer phase of f_{A3}, then deduce the group

delay within the winder bandwidth of 75MHz between f_{A1} and f_{A3}, and get $\Delta N_3 - \Delta N_1$. Then the phase integer ambiguities $\Delta N_1, \Delta N_2, \Delta N_3$ can be solved.

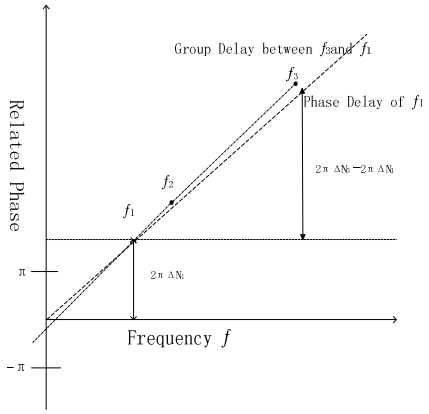

Fig. 3 Schematic diagram of SBI integer ambiguity solver

Processing Flow

According to the mathematical model derived previously, the algorithm processes can be divided: (1).Signals process between stations: divide different signals into groups , conduct delay compensation, Stripe rotation and gain the cross-spectral phases. (2).Signals process between spacecraft: the cross-spectral phases between stations make the difference, and get the double differential phase measurements.(3).Phases delay solution: conduct the integer ambiguity step by step, obtain the double differential delay residuals related to the highest frequency and get the double differential phases delay measurements by adding model values. As shown in Fig.4.

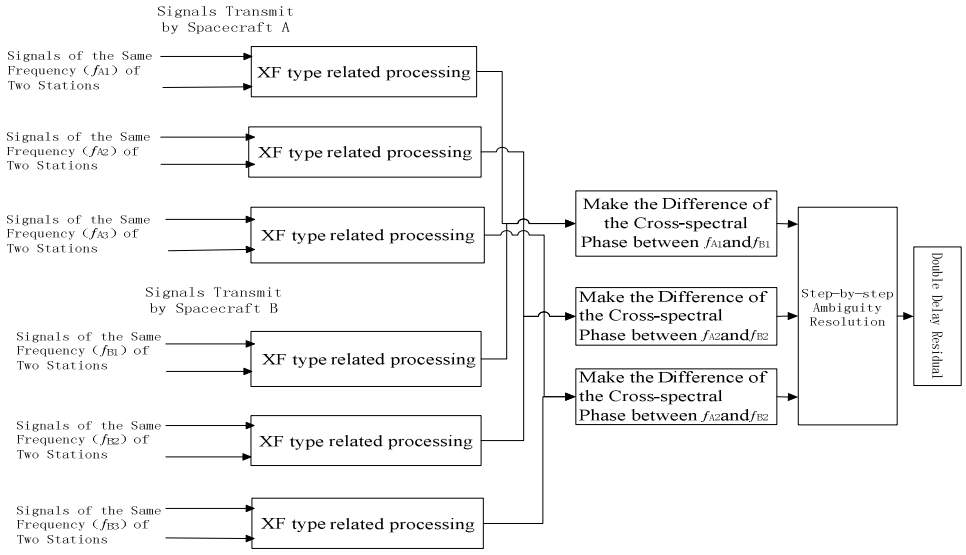

Fig. 4 Flowchart of SBI's processing algorithm

Conclusions

SBI has been recognized as the high-precision interferometric technology, and widely used. This paper describes the applications and prospects, such as Co-located satellites, space rendezvous and docking, landers and patrollers. In the meantime, the principle, processing algorithms, integer ambiguity solver and processing flow are described in detail. At present, China has already commenced the theoretical research and experimental verification. For example China has carried out with observation of SBI and obtained high precision measurements in Chang E III and Firefly One exploration missions. The research of SBI has far-reaching influence and significance.

Keywords: power line communication; OFDM; AR model; back noise; impulse noise

Abstract: Utilizing power line to transmit information speedily and safely is very important and significant. Whereas, the communication environment and construction of power grid are complex and hostile. The paper introduces the application, common modulation technology—OFDM and noise characteristics of PLC. The paper builds an OFDM input and output system and adds the power line noise into the channel, then compares and analyzes the difference between the OFDM output signals in common channel and PLC channel.

1. Introduction

The power line communication (PLC) is defined as a communication technology using power line to transmit data, and putting power grid into communication network. The following figure shows the PLC system.

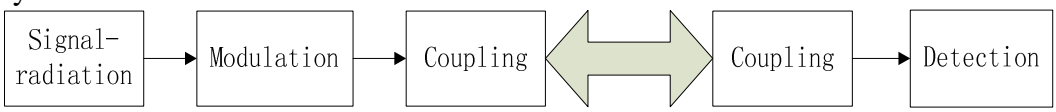

Fig.1 PLC signal system diagram

Nowadays, PLC has been widely used all over the world. Different countries have different applications for PLC. USA devotes PLC to smart home; for UK, PLC is used to automatic meter reading (AMR); and in China, PLC trial communities have been built in many cities.

2. PLC Modulation Method—OFDM

The physical environment of a power line channel is very poor. It is full of noise, interference, and fading, so the common signal is difficult to transfer in the power line. Orthogonal frequency division multiplexing (OFDM) technology can adopt this poor physical environment and fight against frequency selective fading and inter-carrier interference effectively. OFDM is the most common modulation method in PLC.

OFDM technology means converting serial data to parallel data after coding, and modulating N subcarriers in the interval of frequency respectively. Then add the N subcarriers and send then at the same time. In this way, the spectrum of each symbol represents only a small part of the available channel bandwidth. Through the choice of carrier spacing, the frequency orthogonality of each subcarrier in the whole symbol period assures that the receiving end received signal without distortion.

OFDM could be achieved through the IDFT/DFT transform. As shown in the fig.2.

There are N sub-channels in the system, the subcarrier of each sub-channel is

$$x_k(t) = B_k \cos(2\pi f_k t + \varphi_k) \qquad \text{k=0,1,2,3……N-1}$$

The sum of N carriers is

$$\mathrm{S(t)} = \sum_{k=0}^{N-1} X_k(t) = \sum_{k=0}^{N-1} B_k \cos(2\pi f_k t + \varphi_k)$$

Turning into the plural form:

$$S(t) = \sum_{k=0}^{N-1} \mathbf{B}_k e^{j2\pi f_k t + \varphi_k}$$

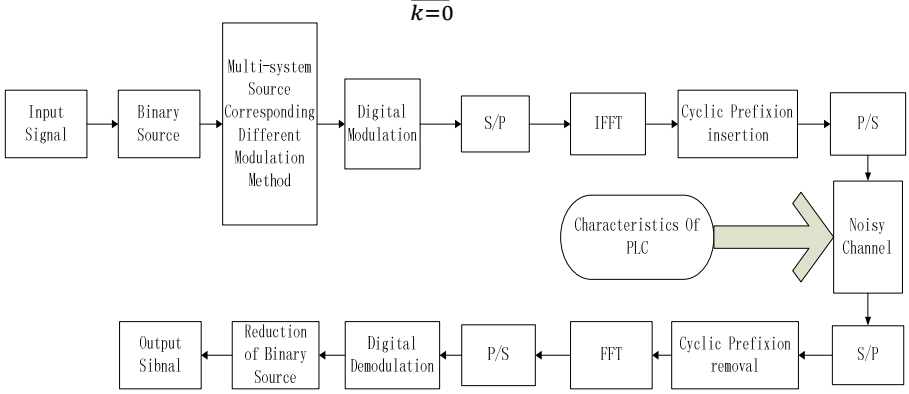

Fig.2 OFDM functional block diagram

$\Delta f = \frac{n}{T_s}$ The minimum separation of subcarrier frequency: $\Delta f_{min} = \frac{1}{T_s}$

Each subcarrier could be modulated in different method. Take QPSK modulation for example, the input signal after modulation, serial/parallel conversion, IFFT and prefixion as shown in the following figure:

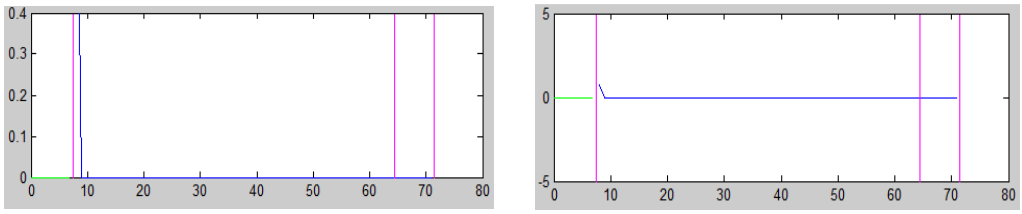

Fig.3 Modulated OFDM symbol amplitude and phase

In the same way, received signal as shown in the figure:

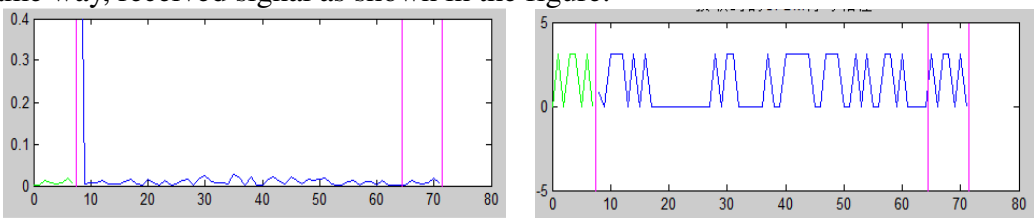

Fig.4 Received OFDM symbol amplitude and phase

The following figure shows the change of the constellation diagram of received signal:

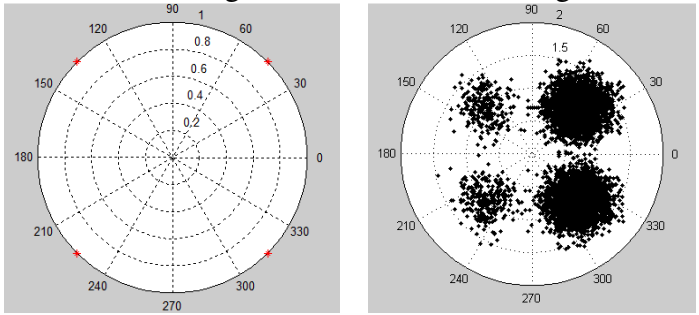

Fig.5 OFDM source QPSK modulation and demodulation constellation diagram

3. The Noise Characteristic of PLC

To build a power line communication system model, in addition to the OFDM signal, power line communication noise is a very important part. Different from command channel noise, the PLC channel noise derived from various electrical appliances, mechanical products and power line itself.

It is not additive white Gaussian noise (AWGN), and its characteristics can change in a short time period. The PLC noise is roughly divided into two categories-- background noise （including colored noises, narrow-band noise and power frequency asynchronous noise）and impulse noise （including power frequency synchronization noise and random impulsive noise）.

3.1 Background Noise

Background noise is a stationary random process and can be received by AR model as shown in the figure.

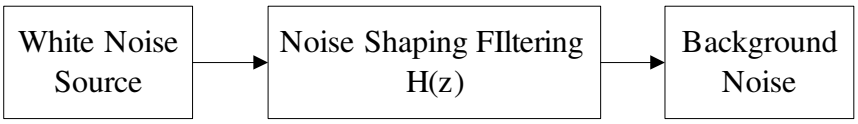

Fig.6 Background noise model

In the figure, the filter function can be described as

$$\mathrm{H(z)} = \frac{1}{\mathrm{A(z)}} = 1/(1 + \sum_{i=1}^{n} a_i\, z^{-i})$$

Utilizing the method of period gram, the formula of discrete series' power spectral density is

$$\mathrm{P}(\omega) = \frac{1}{N}|X_N(\omega)|^2 = \frac{1}{N}\left|\sum_{n=1}^{N-1} x(n)e^{-jn\omega}\right|^2$$

The power spectral density of the AR model background noise as the following figure:

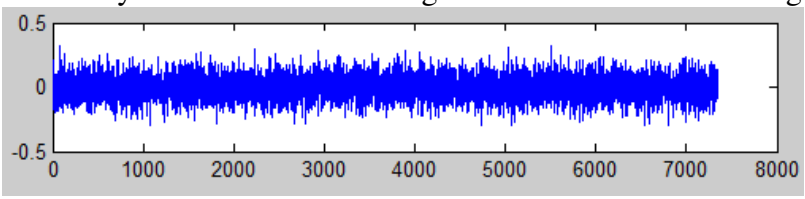

Fig.7 The AR model background noise

3.2 Impulse Noise

The power spectral density of impulse noise is 10 dB higher than the one of background noise. Through statistical analysis of a large number of actual data, we can find that the pulse intensity, pulse width, pulse interval and other parameters of pulse noise obey the exponential distribution, so a single pulse can be represented by a decaying sinusoidal signal.

$$N_{imp} = Ae^{-t/\tau}\sin(2\pi f(t - t_{arr}) + \varphi)$$

In this way, the construction impulse noise is shown in the following figure:

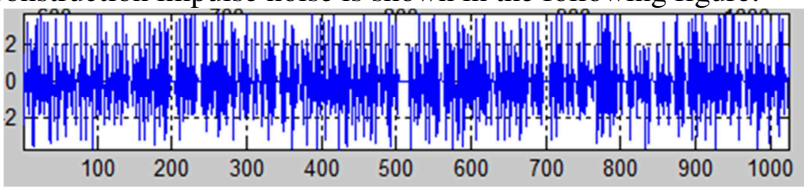

Fig.8 The impulse Noise

After adding the power line noise into the channel, the received OFDM symbol is:

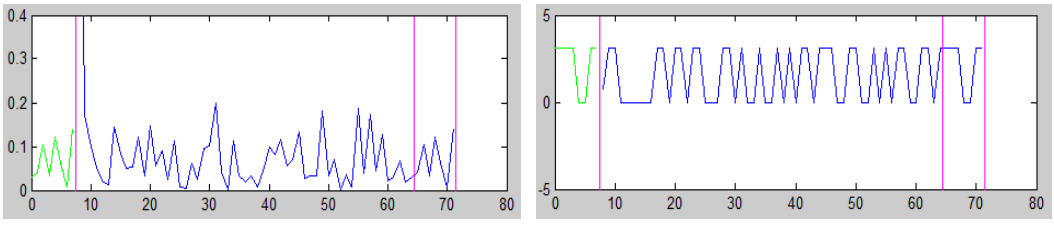

Fig.9 Received OFDM symbol amplitude and phase through PLC channel

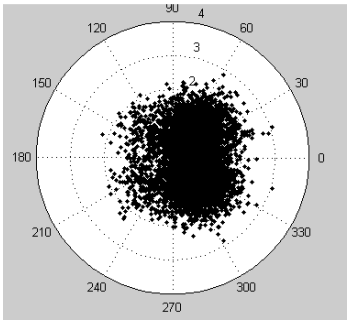

Fig.10 OFDM source QPSK demodulation constellation diagram through PLC channel

4. Summary

Under comparing and analyzing the difference between the OFDM output signals in common channel and PLC channel, we can find that the physical environment of a power line channel is very poor, and the background noise and impulse noise have bad effect on the transmission of OFDM signal.

Although OFDM signal is affected by the PLC noise, it fundamentally keeps the characteristic of input signal, and can be identified and demodulated finally. As a result, OFDM technology can adopt this poor physical environment and fight against frequency selective fading and inter-carrier interference effectively. It is a common and useful modulation method for PLC.

Keywords: STFT, synchronization, PCM/FM

Abstract. According to the characteristics of PCM / FM signals, we propose a new software-based STFT Demodulation algorithm. This paper discusses in detail the basic principles of this demodulation algorithm and implementation process, analyze the complexity of the algorithm, proposed a new method for the extraction and correction code synchronization. Simulation results show that the algorithm not only can effectively suppress the influence of various disturbances in the actual signal synchronization accuracy of the code, with better demodulation performance, and realization of the principle is simple, high efficiency, easy to implement software-oriented real-time treatment.

Introduction

PCM / FM signal as a current standard aerospace monitoring system, at home and abroad have a wide range of applications. Because actually received PCM/FM signal non-stationary random signal, when dealing with non-stationary random signal frequency analysis method is often used, mainly the discrete Fourier transform (STFT) and Wigner-Willie distribution (WD). Related literature STFT algorithm is proposed to resolve the tone and WD-based digital FM signal, has strong anti-noise and anti-fading performance, but a large amount of computation is not conducive to improving the efficiency of software demodulation.[1][2] Signal Demodulation software realization requires not only have good demodulation algorithm performance, but also to the extent possible to reduce the complexity and dependency (such as frequency source) hardware circuit signal processing algorithms, thus contributing to the software environment under real-time signal processing. In this paper actually received PCM/FM IF signal point energy variation proposed algorithm STFT resolve tune of PCM / FM signal is software-based, software technology to achieve a fast, high-precision demodulation.

1 Demodulation algorithm

PCM/FM signal in the main section of a symbol can be approximated as a single carrier frequency sinusoidal signal, you can achieve demodulation PCM/FM signals by calculating the signal in two frequency energy approach. Since the received PCM/FM signal is non-stationary random signal processing method for non-stationary random signal is often used STFT, it is wide enough to use a narrow time window function of the time signal interception, signal thus obtained can be as is stationary, then the Fourier transform to obtain a frequency of the local energy. If you let time windowsill move the timeline, you can get a signal in a time-varying frequency energy in the process, so that you can achieve the demodulated signal. The length of the time window within the sampling points should be close to a symbol, it is a good frequency energy accumulation, improving the performance of signal demodulation.

As can be seen from the definition of short-time Fourier, the sliding time window so that the signal spectrum at the same time have a contact within a window to get the signal spectrum by the discrete Fourier transform (DFT). Due to the use of time windows of signal interception, influenced fence effect and truncated effect, the spectrum is the convolution of the spectral function of the time window and the signal spectrum function, the peak corresponding to the measured frequency energy at the point. DFT is defined as:

$$X(k)=\sum_{n=0}^{N-1}x(n)e^{-j\frac{2\pi}{N}nk} \quad (k=0,1,\ldots.N-1) \tag{1}$$

Seen through the use of a sliding window, a sequence of length N can be decomposed as STFT operation 1×N data vector with N×1 rotation coefficient vector, a calculation amount for the N complex multiplications, (N-1) complex additions. To reduce the amount of computation processing can be used for the rectangular window STFT, this can be achieved in the sliding window algorithm is recursive STFT process, see the derivation of the following formula. Therefore, during the sliding of the rectangular window, for each quantitative calculation STFT 2 complex multiplications and two complex additions.

$$\begin{aligned}
&STFT(n+1,\omega)=\sum_{m=0}^{M-1}x(n+1+m)e^{-j\omega m}\\
&=\sum_{m=1}^{M}x(n+m)e^{-j\omega(m-1)}\\
&=\sum_{m=1}^{M-1}x(n+m)e^{-j\omega(m-1)}+x(n+M)e^{-j\omega(M-1)}\\
&=e^{j\omega}\sum_{m=1}^{M-1}x(n+m)e^{-j\omega m}+x(n+M)e^{-j\omega(M-1)}\\
&=e^{j\omega}\left(\sum_{m=0}^{M-1}x(n+m)e^{-j\omega m}-x(n)e^{-j0}\right)+x(n+M)e^{-j\omega(M-1)}\\
&=e^{j\omega}\left[STFT(n,\omega)-x(n)\right]+x(n+M)e^{-j\omega(M-1)}
\end{aligned} \tag{2}$$

Computer simulation using the ideal PCM / FM signal (signal parameters: carrier frequency 2.4MHz, code rate 800Kbps, 0.7 constant frequency offset, the sampling rate is 20MHz), the signal waveform shown in Figure 1, (a) denotes a modulation symbol, (b) corresponding to said modulation symbol PCM / FM time-domain waveform.

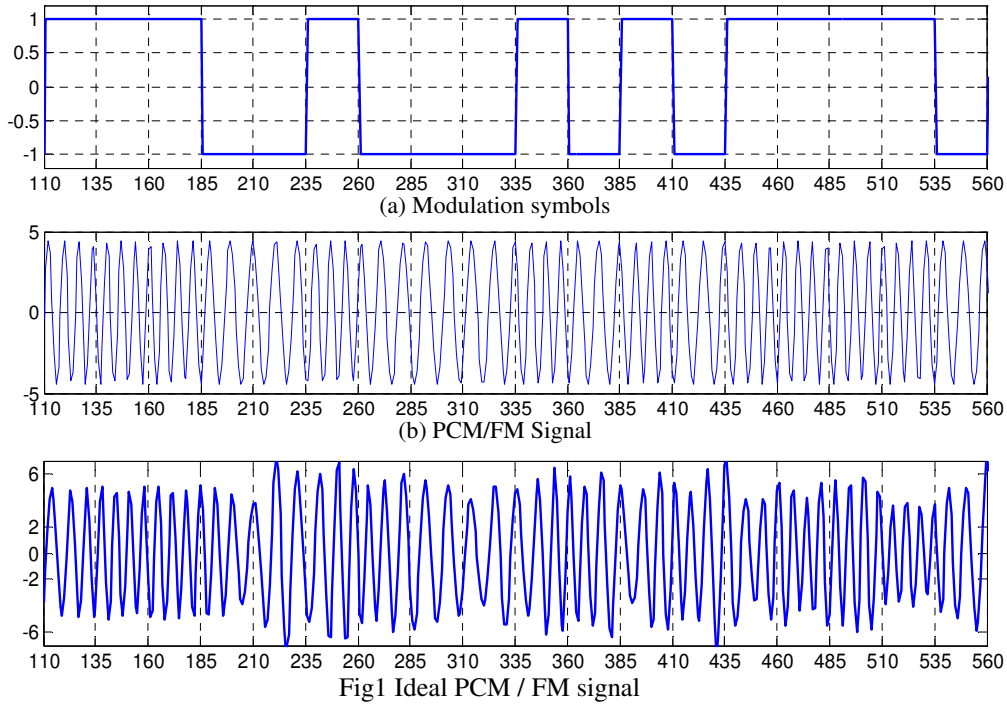

Fig1 Ideal PCM / FM signal

When K an integer and fractional both cases, the simulation calculations using STFT signal energy of the high frequency changes in the point shown in Figure 2.

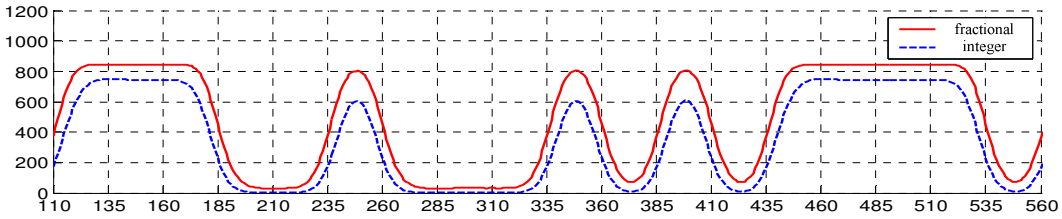

Fig2 Affect the value of K frequency energy

With the above method of calculating the STFT f_0 and f_1 in the case where the signal frequency energy changes with time, as shown in Figure 3.

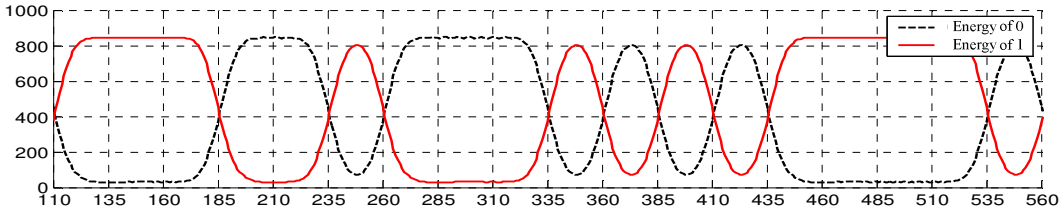

Fig3 Based on PCM / FM signal frequency energy variation method STFT

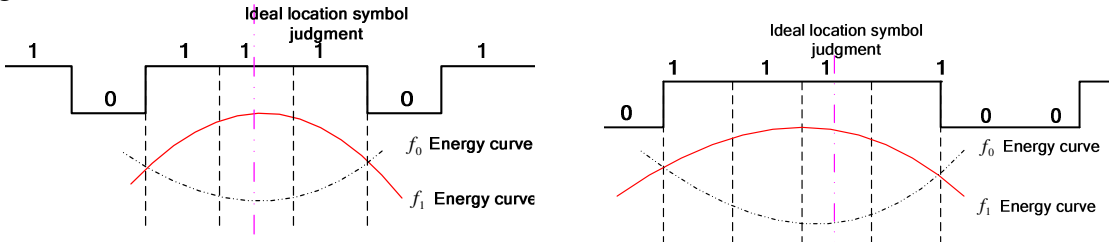
2 Code synchronization

Simultaneous transmission of a digital communication system, the data is correctly received based on the synchronization code based on the right. Code synchronization is receiving data, the symbol judgment must be tightly synchronized with the input symbol, namely the decision to synchronous clock signal must be consistent with the clock signal to send data, otherwise, it will cause even more than the demodulation error code less code. Hardware demodulation circuit method is commonly used to extract code synchronization using a frequency locked loop circuit control code synchronization clock symbol synchronization judgment. Demodulation environment software, hardware suitable for use in the method to establish synchronization codes only through the processing of the input sequence of discrete positioning an intermediate position of a symbol in each symbol of the judgment as the ideal position, to achieve code synchronization extraction and tracking.



（a）Odd symbols ruling position （b）Even symbols ruling position

Fig4 Establishment code synchronization position

After positioning the first code synchronization point to the symbol width of the cycle, in the judgment of every ideal position by comparing the size of the two frequency energy relations, the judgment of the symbol.

Shown in Figure 5, the demodulation process performed in the correction code synchronization correction request of each match, "eye", it is possible to reduce the influence of interference on the code synchronization error, and to avoid the accumulation of errors caused in the demodulation process decreased demodulation performance.

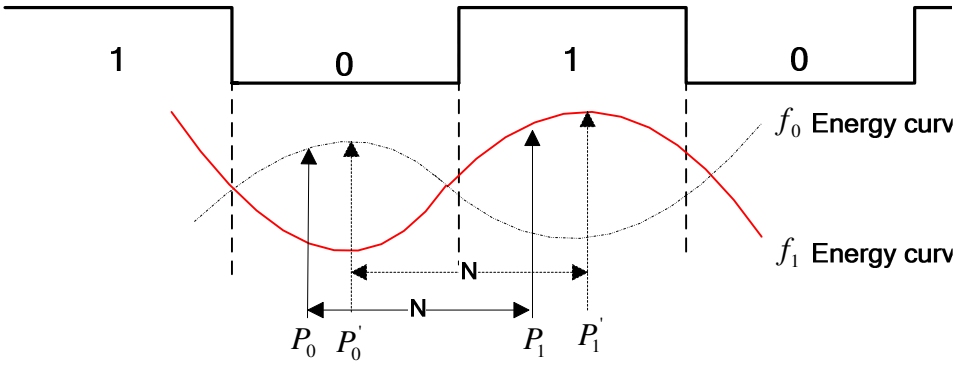


Fig5 Correction code synchronization

3 Performance Analysis

The actual received PCM / FM signal (SNR = 10dB, the code rate is 4Mbps, the carrier 2.4MHz, the sampling rate of 20MHz, the maximum Doppler frequency deviation 60KHz) code synchronization method according to the second part, made in different locations positioning a series of code synchronization point interval between two code synchronization points with the symbol of the relationship between the width of an integer multiple of any adjacent computing, simulation results shown in Figure 7. As can be seen, although the signal is subjected to serious disturbances, but by comparing the energy code synchronization method still has high positioning accuracy, the maximum deviation does not exceed 0.2 times the width of the symbol, the symbol is equivalent to the intermediate in the range of 0.3-0.7 judgment, will not have a serious impact on the verdict. And amended by the code synchronized and timely to avoid the accumulation of synchronization error, ensure that you understand tune performance. The actual received PCM / FM signal demodulation, the average error rate of 1.871×10^{-4}, meet or exceed the performance of the demodulation hardware.

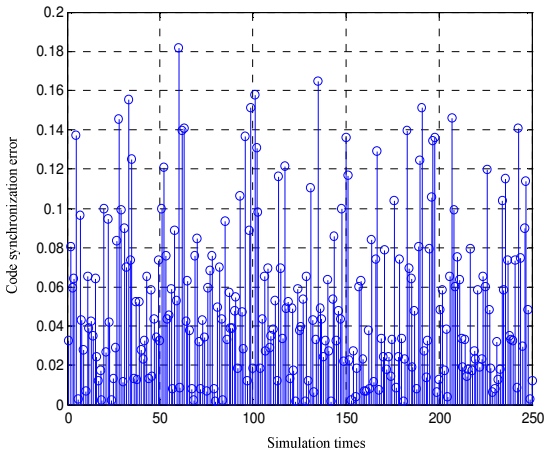

Fig6 Code synchronization performance

Summary

Using the method of calculating the STFT PCM / FM signal energy and frequency point by comparing two frequency energy to achieve the demodulated signal. Such demodulation algorithm can effectively suppress the influence of various disturbances PCM/FM code synchronization signal to the positioning accuracy, and ensure the performance of signal demodulation. Through the truncated data zeros STFT single method of calculating frequency energy, can effectively improve the impact of the fence on the effects brought about by the window function frequency energy. STFT rectangular window function using recursive algorithm greatly reduces the complexity of signal demodulation algorithm, is conducive to the software of the real-time demodulation.

Keywords: Near-infrared spectroscopy, Radix Pseudostellariae, Principal component analysis

Abstract. In order to identify the Zherong Radix Pseudostellariae, a geographical indication products, diffuse reflectance spectroscopy of came from ten different origins were collected by the Fourier near-infrared spectrometer. The spectroscopy was analyzed with Chemometrics method,and the spectroscopy was pretreated by the second derivative, first derivation and minus a straight line condition. The range of spectra was 3996.1-7282.5 cm^{-1}. The Calibration models of Radix Pseudostellariae were established by the qualification testing, principal component analysis, and cluster analysis respectively, and each model was verified. The results show that the optimal model established by the qualification testing, principal component analysis and cluster analysis can effectively identify authentic Zherong Radix Pseudostellariae , and accuracy rate was more than 97.5%. In conclusion, Zherong Radix Pseudostellariae can be identified accurately and quickly by the near-infrared spectroscopy technique.

Introduction

Radix Pseudostellariae is a traditional Chinese medicinal herb, belonging to the family Caryophyllaceae. Perennial herbs heterophylla Pseudostellaria root, Radix Pseudostellariae sweet, slightly bitter, flat. The spleen, lung. Body Moisturizing and nourishing fluid[1-3]. "Zherong Radix Pseudostellariae" is famous for its genuine medicinal materials, its yellow color, crystal, Ne Hoi, strongly smell are famous at home and abroad. The market price of the main Chinese medicinal materials regarded ‘’Zherong Radix Pseudostellariae price" as the standard, leading the domestic medicine market price of Radix Pseudostellariae. In 2007, Zherong Radix Pseudostellariae was implemented geographical origin protection by the State General Administration of Quality Supervision, Inspection and Quarantine. In order to identify the origin of Zherong Radix Pseudostellariae, protect the rights and interests of consumers, "Efficient Recognition Technology" of Zherong Radix Pseudostellariae is necessary to be established.

In recent years, Near- infrared (NIR) spectroscopy has become one of the most attractive and used methods for analysis of agricultural-related products and plant materials allowing for the simultaneous, rapid and nondestructive quantification of major components in the food matrix[4-6]. In order to identify the authentic Zherong Radix Pseudostellariae, Fourier near-infrared spectroscopy was used to collected diffuse reflectance spectra of Radix Pseudostellariae came from 10 different origins, and the analysis model established with the OPUS 6.5 metrology software.

Materials and methods

Materials

The collected Radix Pseudostellariae from different origins was purchased in the local and all products are grown in the year. The raw material was dried at 40 ℃ for 12 hours, pulverized, over a 60 mesh sieve, and equal amount of samples were tested. 94 samples of Zherong Radix Pseudostellariae from 20 plantations of origin protection and 63 samples of non- Zherong Radix Pseudostellariae came from other 9 origins were tested. Geographical origins of Radix Pseudostellariae samples are shown in table 1.

Table 1 Geographical origins of Radix Pseudostellariae samples

Province	Huna	Henan	Zhejiang	Jiangsu	Shandong	Guizhou	Anhui	Chengdu	Guangxi	Total
Sample size	6	6	6	6	6	15	6	6	6	63

Instruments and methods

Samples were scanned in diffuse reflectance mode (4000–12432 cm^{-1}) using a multi-purpose analyzer (MPA) spectrometer (Bruker Optics, Ettlingen, Germany) with a PbS detector and an internal gold background as the reference. NIR spectral data were collected using OPUS 6.5 (Bruker Optics, Ettlingen, Germany) and stored in absorbance format. Each sample was scanned in a quartz curette three times at room temperature with being stirred before each scanning. Then for each sample,three reflectance spectra were obtained and the average of them was used as the data of this sample in calibration or prediction. The scanning parameters were as follows: resolution of 8 cm^{-1}, scanner velocity of 10 kHz; 32 scans for each spectrum.

Results and analysis

Qualification testing

Zherong Radix Pseudostellariae spectra are used as the reference spectra, spectra of other origins were used as the test spectra, the spectral was pretreated by the Second Derivative with smooth point 13 condition, and the spectral range is 3996.1-7282.5 cm^{-1}. The eligibility test index range is selected of 3.6, and then it can be obtained the maximum eligibility index of the reference and test spectra, as shown in Fig. 1.

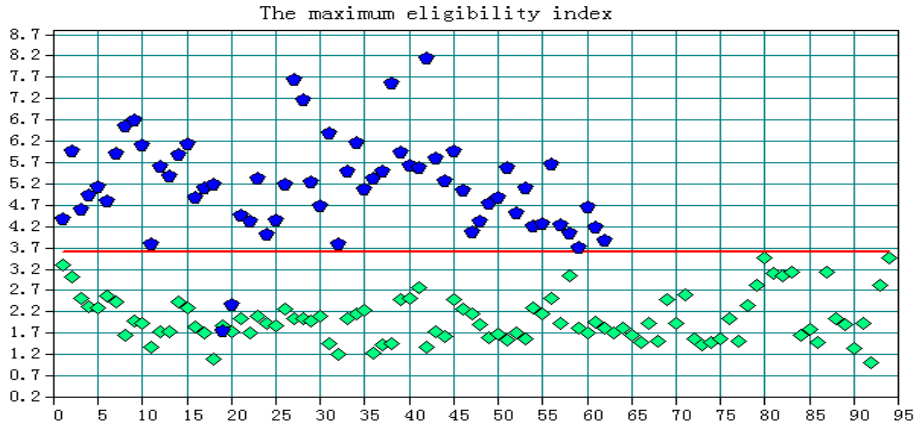

Fig. 1. The maximum eligibility index of the reference and test spectra

◆Zherong Radix Pseudostellariae

▲Other regions Radix Pseudostellariae

As shown in Fig. 1, the index value of the reference spectra was stable distribution near CI=3.6, and Zherong Radix Pseudostellariae is below the index line, it can be seen the Zherong Radix Pseudostellariae quality was stable; In addition, the spectral distribution of the test is clear. The accuracy rate of eligibility test was 98.7%. Therefore, the model can be used to identify the Zherong Radix Pseudostellariae from non- Zherong Radix Pseudostellariae.

Principal component analysis

Principal component analysis (PCA) is a multivariate statistical analysis method, which is to change the original variables, use fewer new variables to replace the old ones. And new variables can maximally express the data structure's characters of the original variables, and at the same time, wipe off useless message. For all spectra, the spectral was pretreated by first derivative and minus a straight line with smooth point 9 condition, the spectral range was 3996.1-7282.5 cm^{-1}, the principal component scores was shown in Fig. 2. The result showed that Zherong Radix Pseudostellariae in the region of the rectangle, and other regions were non- Zherong Radix Pseudostellariae. The

distance is long between Zherong Radix Pseudostellariae and non- Zherong Radix Pseudostellariae, it can be clearly identified, and it was shown quite different ingredients content between Zherong Radix Pseudostellariae and non- Zherong Radix Pseudostellariae.

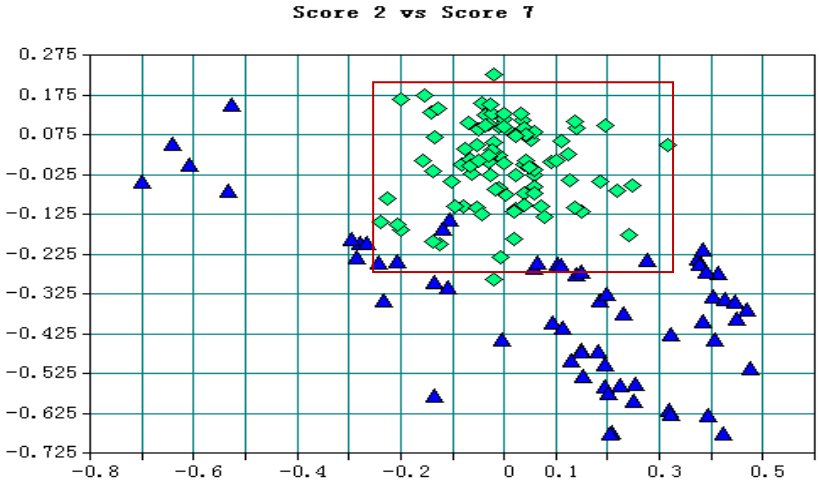

Fig. 2. Principal component scores
◆Zherong Radix Pseudostellariae
▲Other regions Radix Pseudostellariae

Cluster analysis

Second derivation and principal component analysis with smooth point 25 condition was used to pretreat the sample spectra, and the spectral range is 3996.1-12482 cm^{-1}.Samples were cluster analysis after pretreatments of spectra, and ward's algorithm was selected as cluster method, cluster analysis tree was shown in Fig. 3.

The near-infrared spectra between Zherong Radix Pseudostellariae and non- Zherong Radix Pseudostellariae can be clearly distinguished by the standard of cluster analysis, The distance of the spectra shows the similarity of the sample, and the distance of the spectra increased with the sample difference increased, the main component of Zherong Radix Pseudostellariae and other non-Zherong Radix Pseudostellariae was differences greatly.

As shown in Fig. 3, Cluster analysis diagnostic report as followed: all 94 Zherong Radix Pseudostellariae and 2 Jiangsu,1Guizhou,1Hunan sample in a class, 59 non-Zherong Radix Pseudostellariae in another class, The last fusion occurred at 1.910 and the identification of Zherong Radix Pseudostellariae accuracy rate was 97.5%. The identify results are accurate and reliable. Therefore, the method can be used to identify the Zherong Radix Pseudostellariae.

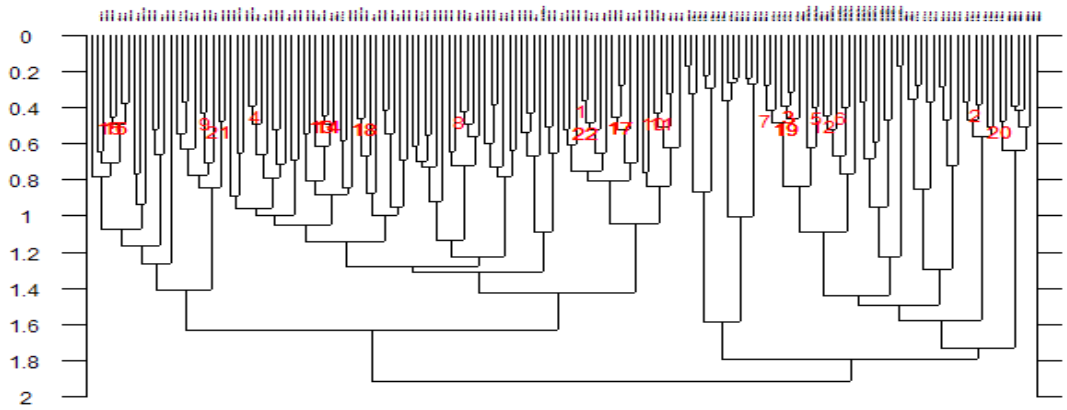

Fig. 3. Cluster analysis tree

Conclusions

The second derivative condition was used to pretreat the sample spectra. The identification models of Zherong Radix Pseudostellariae are established by the qualification testing in the range of 3996.1-7282.5 cm^{-1}, the accuracy rate is 98.7% . Cluster analysis and principal component analysis in the range of 3996.1-12482 cm^{-1} , the accuracy rate is 97.5%. Therefore, Zherong Radix Pseudostellariae can be identifiedeffectively, the near-infrared spectroscopy is combined with metrology methods, which can provide a reliable technique to identify the authentic Zherong Radix Pseudostellariae, and lay a foundation for the protection of the geographic indication products.

Color Image Segmentation Based on Secondary Watershed and GrowCut Algorithm

Jianmei Chen[a], Haiying Lu[b]

College of Computer Science and Telecommunication Engineering, Jiang Su University, Zhenjiang 212013, China.
cjm@ujs.edu.cn,jsdxlhy@163.com

Keywords: image segmentation, cell automata, secondary watershed, GrowCut algorithm, mahalanobis distance, mathematical morphology.

Abstract. GrowCut algorithm is not only an interactive algorithm on the basis of cell automata, but also a multi-label algorithm based on seeds point. Aiming at the GrowCut algorithm usually asks users to partition foreground and background manually and mark a lot more initial seeds. This paper presents an automatic object segmentation method which combining secondary watershed and GrowCut algorithm, here in the following paper refers it to as SWGC algorithm. It firstly using the twice used watershed algorithm to partition the input image, the segmented regions are labeled using Mahalanobis distance, and merged according to the image color and space information, thereafter applying the GrowCut algorithm to perform globally optimized segmentation. The main contribution focuses on performing automatic segmentation which consist of obtain the foreground and background region and generate the seed template of GrowCut algorithm automatically. Thus not only leave out the constraints of user interaction operation, but also avoid the subjectivity and uncertainty. The proposed method reduces the runtime significantly as well as improves the segmentation accuracy and robustness of GrowCut algorithm. Experimental results show SWGC algorithm has superior performance compared to the other related methods.

1 Introduction

Image segmentation [1-2] is a technology and process that refers to make the image into regions with same characteristics and extract the interested objects, appropriate and accurate image segmentation can lay a good foundation for the higher image understanding, as a consequence realization of the real-time, automatic, robust and fast image segmentation. Color image segmentation [3] divide an image into several parts or subsets in accordance with the color rules of color image, extract the image features which are meaningful and need to be applied. It mainly has two main aspects: one is to select the appropriate color space, the other is the adoption of appropriate segmentation strategy and method. With the continual improvement of internet technology and imaging techniques, color image segmentation has become a new technology in demand in daily life, corresponding color image processing has attract more and more attention. In recent years, although there is a constant emerging of new methods in the field of color image segmentation, still it can not satisfy the needs of practical application, by means of a further research to the image segmentation method. It will be meaningful to improve the existing method and put forward more creative and effective method continuously, or that combine a variety of methods, take advantage of their own strengths perform image processing.

Watershed algorithm [4] is a common method for color image segmentation; it has the advantages of simple realization, rapid calculation speed, high precision for segmentation, a good response to the weak edge, can locate the target object accurately, also the object contour line is closed after processed; Faults is sensitive to the noise of the image, the segmentation results also too delicate, prone to over-segmentation, cannot split out the meaningful regions of the image. According to the above views, first conduct a relatively rough segmentation for a given image, preserving enough nodes and feature information which is the segmentation required, under the premise of the target edge line intact.

GrowCut algorithm is an interactive image segmentation algorithm on the basis of cell automata which introduced by Vezhnevets in 2006 [5], the algorithm possesses good robustness, it can be applied to any dimensional images, and complete the difficult segmentation tasks. Due to its distinctive advantages, GrowCut algorithm has attracted many researchers' attention recently [6-8]. The traditional algorithm requires user to mark the target foreground and background, literature [9]and literature[10] put forward the GrowCut algorithm which marked foreground and background by user's dotted line and rectangular marquee respectively, the former label foreground by light-colored dotted lines while dark line marks the background; The latter uses the rectangular marquee tool to surround the target area as the background, then conduct the same way to mark out the foreground in the surround area; For the two marking methods above, the correctly classified of foreground and background area determine the marker of initial seed accurate or not, seeds more or less, or even marker inaccurately will affect the convergence speed and segmentation result. To this end, in this paper we proposed a color image segmentation method that combining secondary watershed and GrowCut algorithm-SWGC algorithm, it marks out the foreground and background, generate the initial seed template of GrowCut algorithm without human interaction automatically. It can simplify user interactive operations, improves the segmentation accuracy of GrowCut algorithm, also reduce the computational complexity.

This paper is organized as follows. Section 2 is devoted to describing the designed approaches for the effective color image segmentation in detail. Section 3 illustrates the experimental results of different segmentation methods, followed by a discussion and comparison of these results. Finally the future work and conclusions are given in section 4.

2 SWGC for Color Image Segmentation

2.1 Secondary watershed

In view of the raw watershed algorithms are extremely vulnerable to noisy pictures; the subtle gray level change of object surface may produce over segmentation. There are several techniques [11] based on image preprocessing, mainly include median filter, low pass filter, Gaussian filter and color morphology et al. As the filters eliminate most of the high frequency from the image, they usually do not preserve borders of the objects. This paper adopts the common operation in morphology for gradient smoothing, Morphological opening and closing reconstruction operation is established on the basis of expansion and corrosion, corrosion before expansion for the open, expansion after corrosion is closed; closed and open operations not only can remove the specific image details which smaller than structural elements, but also avoid global geometric distortion.

To solve the color image gradient of the input image is the first step of pre-segmentation, then perform a segmentation on the color image gradient using watershed method, that is to say, put the minimum value of the gradient image as a starting point for submerged, so as to obtain the dividing line between each valley, this is a watershed process; In view of the large number of the separate area can not significantly reduce the computational complexity; And on this basis, employ the morphology close-opening operation smooth the color gradient image which obtain from a watershed manipulation, proceeding the secondary watershed segmentation, thus not only maintain an adequate amount of information, but also greatly reduces the number of regions.

2.2 Mahalanobis distance

There is a need to define the feature space prior to the calculation of Mahalanobis distance[12], the selection of color space is particularly important for merging the small areas accurately, the color difference of selected color space need to associated with Mahalanobis distance with the purpose of obtaining good segmentation results. CIE(*Luv*) is a kind of uniform color space, which can use the geometric distance of the color space compare different colors, and then measures the small chromatism effectively; Therefore this article adopts the *Luv* color model with linear mapping

properties, in which L represent the brightness, and u, v represent the chromaticity and coordinates respectively.

Mahalanobis distance was put forward by the Indian statistician P.C.Mahalanobis. It is an effective method to calculate the similarity of two unknown sample sets which means the data covariance matrix. Other than Euclidean distance, Mahalanobis distance considers the connection between the various characteristics; also it is independent of the units of measurement. For an average, $u=(u_1,u_2,u_3,...,u_p)$ multivariate covariance matrix vector $x = (x_1, x_2, x_3, \ldots, x_p)$, its Mahalanobis distance $D_M(x)=\sqrt{(x-u)^T\Sigma^{-1}(x-u)}$, not affected by the dimensions, able to eliminate the interference of the correlation between variables is an advantage of the Mahalanobis distance.

2.3 GrowCut algorithm

The core idea of GrowCut algorithm is using the cellular automata theory to calculate the strength relationship between cells and its neighbors iteratively, through the growth and repeated competition changing the state of the cell, and then achieve the foreground target segmentation. This algorithm adopts a new train of thought marking the pixel, specifically; it is not only a multi-label algorithm based on seeds point, but also an interactive algorithm on the basis of cell automata. Cellular automata (CA) [13] were introduced by Von Neumann in 1996, it can carry out complex calculation with the simple behavior rules.

GrowCut algorithm using cell automata as a framework for the segmentation process, a digital image is a two-dimensional array of $m\times n$ pixels; there is a one to one correspondence between pixel point and the cell in the cell automata. The cell state S_p in our case is actually a triplet $(l_p,\theta_p,\overrightarrow{C_p})$, where the label l_p of the current cell, "strength" of the current cell θ_p and cell feature vector $\overrightarrow{C_p}$ defined by the image. The growth process of GrowCut algorithm is an iterative process, in which each cell will have an impact on its neighbor cells, at each time step, the initial cells attempt to attack other surrounding cells, if the attack force is greater than defender's strength, the defending cells have their labels and strength changed to whichever cell originally conquered it. The result of these local competitions is that the strongest cell occupies the neighboring pixels and gradually spread over the image. This process repeats until the entire cell's states stop changing, or after a maximum number of iterations, all cells will reach an equilibrium state and then the algorithm converges, the end result is a set of foreground and background pixels that describe the object segmentation in the image.

2.4 Concrete algorithm design

In the light of above ideas, the main steps of SWGC can be concludes as follows:

Step 1. For a given color image, First pre-processed by the secondary watershed algorithm, acquire the rough segmentation of the image, then employ the close-opening operators in mathematical morphology do the smoothing, fusing some isolated points in the region, better to avoid over-segmentation and information loss, obtain a limited number of initial segmented small regions.

Step 2. Do the color image edge detection which based on canny operator in the first place, then take the center of the object as mask, use the mask to obtain the color information of the Luv feature space, and compared with other segments, which are taken from secondary watershed segmentation output. Afterwards, grow that mask on the basis of dissimilarity function named Mahalanobis distance between mask and other parts, if they are kind of similar then merge that region to the mask.

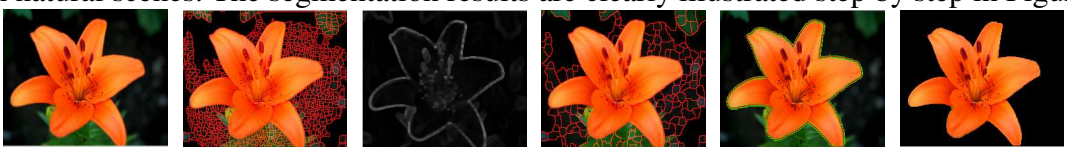
Step 3. The final mask which merged the most likely segments was set as the foreground information, and the remaining regions are utilized as background information in GC algorithm, so make a distinction between object and background without manual operation.

Step 4. According to the foreground and background information, employs morphological reconstruction technology manipulates the foreground and background, take its local maximum point

as the foreground and background seeds point respectively, generate the initial seed template of GrowCut method automatically, then perform the final segmentation for further.

3 Results and Discussions

SWGC algorithm proposed in this paper is applied for the object segmentation of the color images with natural scenes. The segmentation results are clearly illustrated step by step in Figure 1.



(a) (b) (c) (d) (e) (f)

Figure 1. (a) Original image (b) A watershed (c) Morphological smoothing (d) Secondary watershed (e) GrowCut segmentation (f) Extract the foreground object

Compared with traditional GrowCut algorithm's segmentation results, SWGC algorithm has a better performance which shown in Figure 2, Table 1 describes the runtime between GrowCut and SWGC algorithm. Thus it can be seen from that the proposed method can obtain the edge contour of the image accurately, also make the results tend to be more overall consistency; While traditional GrowCut algorithm existed over-segmentation and undivided regions, has a poorly effect; Meanwhile, Compared with the conventional manual marking GrowCut algorithm, SWGC can generate the desired foreground and background area automatically, has a faster execution time.

experiment image	Computational Time(s)	
	GrowCut algorithm	SWGC algorithm
White rabbit	5.8735	2.9219
jasmine	7.4688	4.7031

To further verify the validity of the proposed algorithm, this paper directly comparing the experimental results with the results of the algorithm in the related literature. The contrastive experiment results using the following three methods, MSNcut[14], MSAP [15] and SWNcut [16]. Figure 3-5 depict the test results of color images using four methods, and we can make the following observations from Figure 3-5 : The edge of the image obtained by MSNcut algorithm present obvious jagged, the effect is not ideal; MSAP algorithm segmentation generate quite smoother image edge, but there are quite a few small isolated area; SWNcut algorithm can accurately locate the image edge profile, yet the adjacent areas segment of multi-objective image is not quite accurate; For all the experimental results, SWGC algorithm, by contrast, partitions effectively the natural scenes into several meaningful regions and provides more accurate and complete object region. Time comparison between SWNcut and SWGC algorithm shown in Table 2, as can be seen both methods have performed pre-segmentation by secondary watershed, and got the same number of regions, under this condition, adopt the Ncut algorithm and GrowCut algorithm for re-segmentation respectively, GrowCut operation time is slightly less than the Ncut algorithm, thus the computing speed is improved.

4 Conclusions and Looking

A fast and effective SWGC method for color image segmentation has been designed in this paper. The strength of such approach is that it integrates the advantages of the two algorithms which have a faster processing speed and a more satisfactory segmentation result; it ensures the integrity and accuracy of the segmented regions and work well for all kinds of style images. In addition, compared with other related methods, such as the traditional GrowCut, MSNcut, MSAP, SWNcut et al, the SWGC algorithm indeed has a better performance. Experimental results verify the feasibility and practicality of the SWGC; it can be described as an efficient method for color image segmentation.

Future work will concentrate on exploring theoretical properties of the algorithm and seeking other algorithm which is simple, faster, obtaining better segmentation results as GrowCut algorithm's pre-processing in the first stage; In the next stage, the main task is to integrate the rich texture information of image, and apply to the segmentation algorithm while considering using color information.

Tracking Optimization of FH signal based on Wiener Filtering

He Qian[1, a], Wu Guangzhi[1,a] and Wu Yanjun[1,a]

[1]China Satellite Maritime Tracking and Control Department, China

[a]348237548@sina.com

Keywords: FH (Frequency-Hopped), wiener filter, tracking accuracy

Abstract. Comparing with the traditional fixed carrier frequency signal, using FH (Frequency-Hopped) signals improved the performance of anti-interference of the TT&C system when bring the low signal tracking accuracy. In order to solve this problem, this paper proposed a loop structure of using wiener filter, the filter coefficient was deduced. Simulation results show that the loop tracking precision was increased after the optimization, and the improvement has relations with the filter order n. When $n=10$, the speed measuring precision reached 30cm/s which was increased about 3 times than did not use wiener filter.

Introduction

With the development of electronic warfare technology, it is a big challenge of communication in harsh environments for effective, in order to ensure the normal operation of the system in order to obtain favorable space superiority is the future development trend of the system. Using FH (Frequency-Hopped) spread spectrum signal is to improve the system in harsh conditions interfere with the satellite monitoring in effective monitoring system [1]. But using FH signal and brought the loop tracking accuracy is not high, so that the accuracy of measurement and control system is not high speed. Control signals for a fixed carrier frequency, using ordinary loop speed precision tracking signal about 2cm/s, measurement precision under the same circumstances hopping signals about 90cm/s.

In this paper, the monitoring system used in FH spread spectrum signal is not high speed precision problem, Wiener filter for tracking loop optimization.

1 Structural analysis

The so-called statistical filtering for random signals is to filtering from a mixture of random measurement error signal as close as possible to the true value of their estimated useful signal in factually. In the context of this article, because the characteristics of FH signals can not be used in case of PLL loop FLL loop with its tracking signal tracking, and adding auxiliary module hopping pattern in FLL loop to remove due to the hopping Carrier frequency agile problems caused[2]. But the tracking accuracy using frequency hopping signal tracking loop FLL limited Solutions to this problem is to use statistical filtering of the measured loop data estimates and projections, by this method to increase the frequency tracking accuracy, thus improving system The measurement precision. First through a Wiener filter, this article before using Wiener filter frequency tracking performance of the proposed method is mainly optimized for tracking the signal into the loop, the structure is shown in Figure 1.

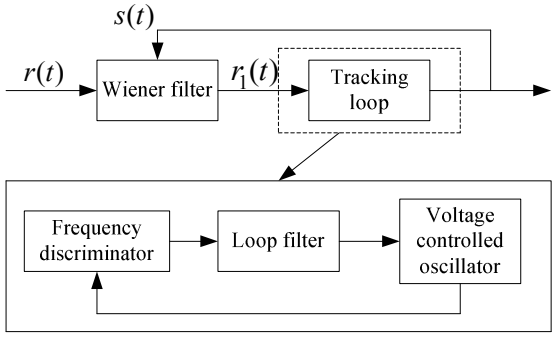

Fig 1 Tracking loop structure with Wiener filter

Where, the structure block diagram of the Wiener filter can be described in Figure 2.

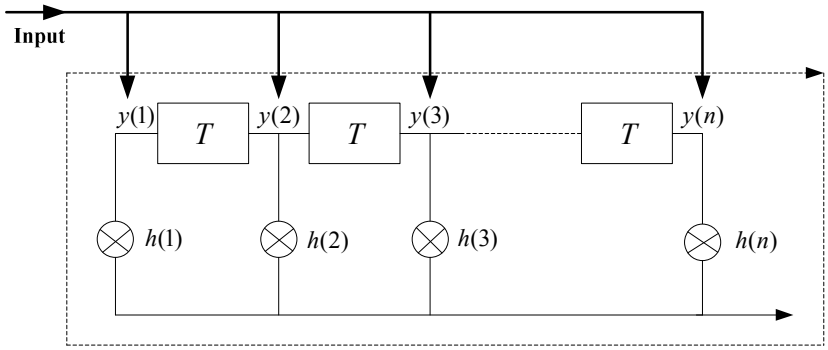

Fig 2 Non-Recursive Wiener filter structure diagram.

Assuming useful signal x is a random variable. $y(k)$ is sampled at different time points of the measured measurement values of the useful signal x, that is, the signal captured completed $r(h)$, $h(k)$ for the filter weighting coefficients. $v(k)$ is introduced in the measurement process additive noise, and uncorrelated with the random signal x, based on the above assumptions, we can get:

$$y(k) = x + v(k) \tag{1}$$

Suppose we have measured n samples value of $y(k)$ as $y(1), y(2), ..., y(n)$, then, the next step is to use a Wiener filter for further processing of these measurements, in order to make possible approximation to estimate x, we follow the statistical estimation theory habits, the estimated value of x is set to $\hat{x}$.

The purpose of the Wiener filter is thought captured by Wiener filter estimation completion signal, to produce a new received signal so that the signal obtained by the estimation as close to the useful signal. In essence, is removed by estimating the noise, thereby improving the signal to noise ratio of the received signal. Specific workflow:

First, the input signal has been captured to complete Wiener filter, a Wiener filter in accordance with the signal workflow $r(t)$ is processed, a new estimate of the signal $r_1(t)$, as estimated by remove noise and improve the signal to noise ratio.

Second, the estimated signal is input to the FLL loop, the traditional workflow lock loop tracking of the signal to obtain a frequency tracking loop to recover the received signal in the voltage controlled oscillator.

2 Filter coefficient optimization

The above section describes the structure of non-recursive type Wiener filter, which Wiener filter is the easiest way to achieve an average sample value estimator[3], which means that the weighted coefficients $h(1), h(2), ..., h(n)$ is equal to $\frac{1}{n}$, then the estimation value of x is arithmetic average of n sample value, and it is shown as

$$\hat{x} = \frac{1}{n}\sum_{i=1}^{n} y(i) \tag{2}$$

However, this is not a mean square estimation method to estimate the optimal sense of the estimation error is minimized, so next we mean square estimation error is minimized as an optimal criterion. The weighting coefficient $h(1), h(2), ..., h(n)$ is optimized such that the filter output the minimum mean square estimation error.

According to the filter structure shown in Figure 2, the general expression of the estimated value $\hat{x}$ of the Wiener filter is

$$\hat{x} = \sum_{i=1}^{n} h(i)y(j) \tag{3}$$

Where, $h(i)$ is the filter coefficient of the filter, and it is necessary to optimize section as well. From the following formula (3) starting under the minimum mean square error estimation criterion, the optimum filter coefficient calculating $h(i)$ such that the estimated mean square error filter is minimal, so that the loop tracking precision is optimum.

Due to the estimating value of random variable x is $\hat{x}$, therefore, the general expression for the mean square estimation error is

$$P_e = E[(\overline{x}\hat{x})^2] = E\left[\left(\overline{x}\sum_{i=1}^{n} h(i)y(i)\right)^2\right] \tag{4}$$

Because we need to strike the filter coefficients $h(1),h(2),...,h(n)$, and in accordance with the criterion of minimum mean square error estimation, so you can find the mean square error P_e partial derivative with respect to each of the weighting factors, and to make derivative value is 0, that is

$$\frac{\partial P_e}{\partial h(j)} = -2E\left\{y(j)\left[\overline{x}\sum_{i=1}^{n} h(i)y(i)\right]\right\} = 0,\ j = 1,2,...,n \tag{5}$$

Simplifying the formula (5), and we can obtain:

$$\sum_{i=1}^{n} h(i)E\left[y(i)y(j)\right] = E\left[xy(j)\right],\ j = 1,2,...,n \tag{6}$$

Wherein, $E\left[y(i)y(j)\right]$ is the autocorrelation sequence of measured values, and we denote it as $P_{xy}(i,j)$; $E\left[xy(j)\right]$ is the cross-correlation sequence between the random signal x and the measured value, and denoted by $P_{xy}(j)$.

Thus, the formula (6) can be written as:

$$\sum_{i=1}^{n} h(i)P_y(i,j) = P_{xy}(j),\ j = 1,2,...,n \tag{7}$$

Spreading formula (7) and we can get:

$$\begin{cases} P_y(1,1)h(1) + P_y(2,1)h(2) + ... + P_y(n,1)h(n) = P_{xy}(1) \\ P_y(1,2)h(1) + P_y(2,2)h(2) + ... + P_y(n,2)h(n) = P_{xy}(2) \\ \quad . \\ \quad . \\ \quad . \\ P_y(1,n)h(1) + P_y(2,n)h(2) + ... + P_y(n,n)h(n) = P_{xy}(n) \end{cases} \tag{8}$$

Where, $P_y(i,j)$ and $P_{xy}(j)$ are known parameters, $h(1),h(2),...,h(n)$ is willing to be solved. So the above formula can be determined by the filter coefficients $h(1),h(2),...,h(n)$, and we completed the minimum mean square error estimation filter criterion optimization.

According to the analysis above, and apply it into FH signal tracking, $y(k)$ is the received signal which is mixed with the noise, x is the useful signal, and we are aim reduced the difference of the them through using filter as far as we can.

3 Simulation results and analysis

According to deducing of filter coefficients $h(1),h(2),...,h(n)$ above, the derivation, such that the filter is estimated based on the minimum mean square error criterion optimization. In this section, the use of non-recursive type Wiener filter optimized by observing the actual simulation loop track after track results. First we observed in the remaining frequency difference $f_{in} = 20Hz$, Doppler rate of change $f_a = 5Hz/s$, preflight integration time $T_{coh} = 5ms$, loop bandwidth $B_L = 20Hz$, ratio of carrier to noise $C/N_0 = 35dB$, traditional FLL loop to jump the results of the tracking signals is shown in Figure 3.

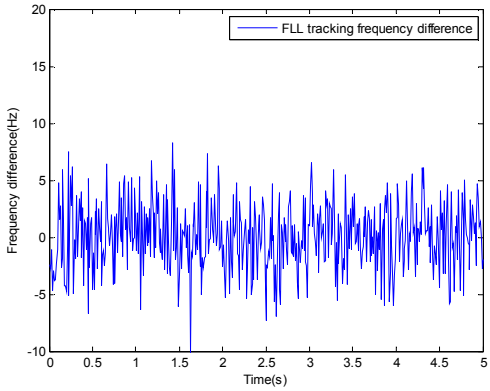

Fig 3 The relationship with delay interval, code sequence and likelihood value

Then, we simulate results of the loop after using wiener filter, and shown in figure 4.

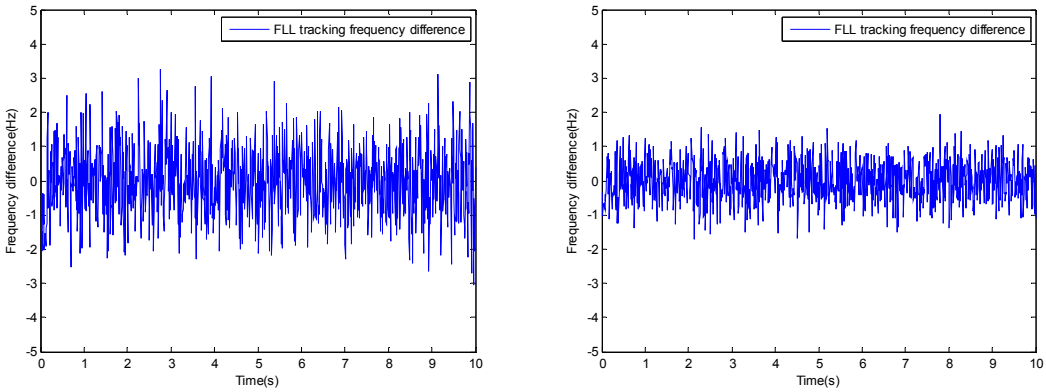

Fig 4 Loop tracking frequency difference of $n=5$ and $n=10$ respectively

Obviously, the tracking frequency difference is less than the original loop after using the optimizing loop, and with the processing number increasing of $y(k)$ each time in Wiener filter, the improvement effect of the tracking frequency difference is becoming better.

Summary

In this paper, we proposed a method of using wiener filter to optimize traditional carrier tracking loop, and derived the weighting coefficients of Wiener filter. Simulation results proved that the loop tracking precision improving accuracy is greatly increased for FH signal by using wiener filter. When the order of the filter is 10, the speed measurement accuracy of the system is 30cm/s, and it is three times accuracy improved than without using Wiener filter.

Detection of Nonlinear Frequency Modulated Signal Based on Fractional Fourier Transform

Wu Yanjun[1, a], Tao Min[1,a] and Zhou Minqi[1,a]

[1]China Satellite Maritime Tracking and Control Department, China

[a]348237548@sina.com

Keywords: Nonlinear frequency modulated signal, fractional Fourier transform (FRFT), linearly approximation approach, Wigner-Ville distribution

Abstract. Based on fractional Fourier transformation (FRFT), the feature of the signals which vary smoothly from time domain to frequency domain is given. The FRFT method is applied to the estimation and detection of nonlinear frequency modulated signals to which piecewise linearly approach. Wigner-Ville time frequency distribution of the signals is used after approaching and the masking results of the original signal accumulate energy as detecting statistic. A signal detector based on energy accumulation from time frequency domain in the angle of analysis of both time and frequency is proposed. Finally, a comparison with traditional non-coherent energy accumulation methods is made, which shows the proposed method has superior performance.

Introduction

Target detection in many areas (such as radar, sonar, etc.) has a wide range of applications. Traditional detection problem is divided into three parts [1]: the detection of a known signal in noise, random noise signal detection signal detection with unknown parameters and noise of. The former two problems were solved by a matched filter or a matched filter [2]. The third case is random since the signal waveform detection method is non-parametric method based on detection.

Time-frequency analysis is a useful tool for dealing with non-parametric detection problem. Its main idea is the one-dimensional time-domain transformation when the two-dimensional frequency distribution. The basic time-frequency distribution is divided into two types: atomic decomposition, such as short-time Fourier transform and wavelet transform; bilinear distribution, such as when the Cohen class frequency distribution [3]. In the past decades, the time-frequency detection theory of random signal had a rapid development. The fractional Fourier transform is applied to the signal detection and parameter estimation has attracted more and more attention, including linear FM signal (chirp signal) and so on. But these are the premise of linear signal to start, and in the actual signal processing, nonlinear signal occupies a large proportion, while the use of linear estimation method to detect non-linear signal is more practical application significance.

Fractional Fourier transform as a time-frequency analysis method has a number of excellent performance. In the text of the algorithm, using the Wigner-Ville distribution to indicate when the signal frequency distribution FRFT for piecewise linear approximation of the FM sub N section of the signal, then the signal will be approaching the Wigner-Ville transform, and finally results of two Wigner-Ville distribution a "mask processing", access to new distribution. According to the distribution of accumulated energy detection can be applied in order to take full advantage of the signal in the frequency domain information. In this paper the fractional Fourier transform and combine the energy accumulation and detection applied to estimate the unknown signals to analyze the detection performance of this approach. Experimental results show that the proposed method obtained good detection results.

1 FRFT and parameters estimation

1.1 Fractional Fourier Transform

Fractional Fourier transform by V. Namias in 1980 from a mathematical point given. It can be interpreted too frequent surface rotation operator, is about the axis signals in the time-frequency surface do rotate counter-clockwise. This property makes it suitable for analysis of LFM signal. Fractional Fourier transform is a generalized Fourier transform, the signal can be seen as representation on u axes counterclockwise rotation α axis on the timeline.

Fractional Fourier transform is defined as

$$X_p(u) = \{F^{\alpha}[x(t)]\}(u) = \int_{-\infty}^{+\infty} x(t)K_p(t,u)dt \tag{1}$$

The conversion kernel function is

$$K_p(t,u) = \begin{cases} \sqrt{\dfrac{1-j\cot\alpha}{2\pi}}\exp[j(\dfrac{1}{2}u^2\cot\alpha - ut\csc\alpha + \dfrac{1}{2}t^2\cot\alpha)] & \alpha \neq n\pi \\ \delta(t-u) & \alpha=2\mathrm{n}\pi \\ \delta(t+u) & \alpha=2(n+1)\pi \end{cases} \tag{2}$$

Where, p is the FRFT order, α is the rotation angle, and $\alpha = p\pi/2$.

The energy of white noise evenly is distributed over the entire time-frequency plane, the probability of the energy accumulation FRFD small. According to the nature of the fractional Fourier transform, chirp signal on FRFD energy accumulation appears, therefore, the position of the energy accumulation can occur via two-dimensional fractional plane to estimate the chirp signal the initial frequency and tune the frequency to complete the estimate of the parameters.

1.2 Dimensionless normalized and parameter estimation

Assumes that the original signal $f(t)$ is in the time interval $[-t_b/2, t_b/2]$, and the frequency domain is in the interval $[-f_b/2, f_b/2]$, t_b and f_b are the time width and bandwidth of the signal respectively. In order to transform the time domain into a domain of dimension 1, we introduce a normalized scale factor m, and define a new dimension following coordinates

$$x = t/m,\ v = fm \tag{3}$$

the new coordinate system realized normalized dimensionless, and $m = (t_b/f_b)^{1/2}$, the length interval of the two interval are $x = (t_b f_b)^{1/2}$, then the two normalized interval is $[-x/2, x/2]$, the sampling interval is $\frac{1}{x}$.

Expression of Chirp signal is defined as

$$f(t) = a_0\exp[j(\varphi_0 + 2\pi f_0 t + \pi\mu_0 t2)] + W(t),\ -t_0/2 \le t \le t_0/2 \tag{4}$$

Where $W(t)$ is additive Gaussian white noise, μ_0 is Chirp rate, f_0 is center frequency, and a is the FRFT order of the peak. The relationship expression between FRFT domain coordinate u and u_0, f_0 is defined as

$$\begin{cases} \mu_0 = -\cot(p\pi/2) \\ f_0 = u\csc(p\pi/2) \end{cases} \tag{5}$$

Assuming the signal frequency before normalization and after normalization is μ_0 and μ_0' respectively, the relationship between them is

$$\begin{cases} \mu_0' = \mu_0 m^2 \\ f_0' = f_0 m \end{cases} \tag{6}$$

2 Scheme of signal detection in time-frequency domain

Noise and clutter weak maneuvering target detection, radar and sonar has always been a challenging task in the field. Detect a weak goal requires a long observation time. However, in the long accumulation of target echo phase history is difficult to use a few parameters modeling. Thus, object detection becomes a non-parametric detection. Here, the echo can be assumed to be maneuvering target with unknown a smooth instantaneous frequency curve linear FM signal and noise can be modeled as a complex additive white Gaussian noise. Target detection can be equated to the complex Gaussian white noise in the background to detect unknown FM signal problems [4]. This is a typical binary hypothesis testing problems.

$$\begin{cases} H_0 : x(n) = w(n) \\ H1 : x(n) = s(n) + w(n) \end{cases} \tag{7}$$

Here, $x(n)$ is the time sequence of the tested signal; $s(n)$ is an unknown Chirp signal corresponding to the target; $w(n)$ is complex white Gaussian noise with mean zero and variance σ^2 independently.

2.1 Segmentation parameter estimation

Observation of the unknown signal x_1 (its length is M) is shown as

$$x_1 = [x_{11}, x_{12}, ..., x_{1N}]^T \tag{8}$$

Where N can be divided by M .

$$x_{i1} = \left[x_1\left((i-1)\frac{M}{N}+1\right), x_1\left((i-1)\frac{M}{N}+2\right), ..., x_1\left((i)\frac{M}{N}\right)\right]^{\mathrm{T}}, \ i = 1,2,...,N \tag{9}$$

Thus, the unknown signal x_1 is divided into N segments evenly, within the time-frequency plane is represented by Wigner-Ville distribution

$$W_{1i}(t,f) = \int x_{1i}(t+\frac{\tau}{2}) x_{1i}^*(t-\frac{\tau}{2}) e^{-j2\pi f\tau} d\tau, \ i = 1,2,...,N \tag{10}$$

Described in the previous section using the dimensionless normalized parameter estimation method, each signal can be approximated as a linear FM signal, the initial frequency of f_0, chirp rate μ_0. Thus, the segment of unknown chirp signal is approximately expressed as a form of formula (11) shown as follow.

$$x_{2i}(t) = \exp[j(\varphi_0 + 2\pi f_0 t + \pi\mu_0 t^2)] \tag{11}$$

2.2 Accumulation of energy detection based on Wigner-Ville distribution

Do Wigner-Ville transform for every segment signal and represented as

$$W_{2i}(t,f) = \int x_{2i}(t+\frac{\tau}{2}) x_{2i}^*(t-\frac{\tau}{2}) e^{-j2\pi f\tau} d\tau, \ i = 1,2,...,N \tag{12}$$

We use Wigner-Ville distribution to represent signal $x_{2i}(t)$, and then accumulated energy of all the tiny segment signal by using the “mask” method.

$$Y_i = \sum_f \sum_t W_{1i}(t,f) W_{2i}(t,f), \ i = 1,2,...,N \tag{13}$$

Where Y_i is energy of unknown signal in i th segment. the ”dot product” operation in the “mask” method can retrain noise very well and give prominence to the time-frequency distribution characters of the signal. For the new time-frequency distribution, it accumulates energy of all the N segments. As a inspection statistical variable, its computation formula is shown as

$$Y = \sum_{i=1}^{N} Y_i \tag{14}$$

3 Simulation and result analysis

In this section, we do FRFT for the unknown parameters nonlinear frequency modulated signal, and compute it by dividing it into N parts.

If the signal is separated by eight segments, the SNR is -5dB. We assume each segment of the nonlinear frequency modulated is Chirp signal, and it is restrained in range of $[-63/1024, 63/1024]$ according to discrete dimensionless scaling normalization method, the sample frequency is 512Hz, and length of noise is 512 equally. According to formula (4), we can calculate that the normalization scale factor is equal to $\sqrt{63}/512$ .Thus, we do FRFT for the sum of signal and noise in all the order in range of $[0,2]$ by the step of $1/180$ and searching the peak and its coordinate, then, estimate signal parameters according to the relationship between chirp rate, center frequency, FRFT order and the position of FRFT domain as shown is formula (6). This is the approximate expression of nonlinear frequency modulated signal by using chirp signal parameters estimation. Finally, we can find out performance of the method by comparing the original signal with the approximate expressing chirp signal, and it is shown in figure 1.

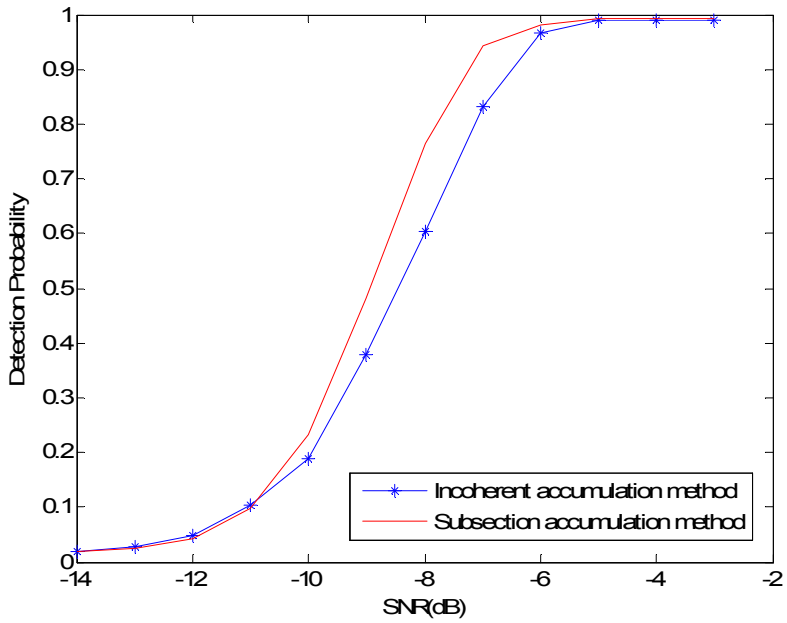

Fig1 Two nonlinear frequency modulated signal detection Probability curves

Summary

We present nonlinear frequency modulated signal detection method based on time-frequency analysis technique of parameters estimation by using FRFT in this paper. Piecewise parameter estimation method can be used in the piecewise linear approximation of nonlinear FM signal FM signal frequency curves. Based on the energy distribution and the resulting characteristics of the new mask, the unknown signal can be applied with a noise detection process, thus, it can improve the detection performance.

Keywords: Parameter estimation; fractional Fourier transform; chirp signal

Abstract. The general method time-varying amplitude linear FM signal parameter estimation, the proposed parameter fractional Fourier transform for time-varying estimates of the magnitude of the chirp signal, and the related issues of a more in-depth research. Study the time-varying amplitude of the initial phase chirp signal, the initial angular frequency, modulation frequency and amplitude information extraction and estimation methods, and the magnitude of the Gaussian function varies with the magnitude of random variation and chirp signal for the object properties (parameters on parameter estimation estimate the mean square error) were simulated.

Introduction

The fractional Fourier transform (FRFT) for linear FM (Linear Frequency Modulation, LFM, or Chirp) signal detection and parameter estimation in the past two years has attracted more and more attention. The literature [1-2] first studied the fractional Fourier transform in SAR radar moving target detection and imaging applications; The literature [3-4] The fractional Fourier transform is applied to spread spectrum communications broadband interference suppression and achieved good results; The literature [5] specifically studied the detection and parameter estimation based on fractional Fourier transform LFM signal, and gives a detailed performance analysis.

However, these studies are under constant signal amplitude of the fundamental hypothesis of unfolding. In fact time-varying amplitude chirp signal has a broader application background in engineering practice. In actual signal processing, the signal amplitude due to fading or other reasons not remain constant. For example, in mobile communication applications, a Gaussian minimum shift keying signal to band limit the radiated power of the base band signal generated Gaussian pulse, rather than a general rectangular wave, is a time-varying amplitude of the chirp signal. A class of radar echo signal detection system may be affected by two factors: the relative movement between the target and the receiver is Doppler shifted, the target range of the reaction medium, or scattered signal will be distorted, and therefore, echo signal is actually a time-varying amplitude of the linear FM signal, in addition, also in the presence of signal interference during transmission and recording modulation, such as the modulation caused by ionosphere domino offset in shortwave communication and civic electricity interference when a electrocardiograph is recording cordis electricity signal. All these cases show that when using variable amplitude chirp signal as engineering analysis model is more practical significance.

1 The main proposed methods of AM-FM signal detection and parameter estimation

Time-varying amplitude linear FM signal is actually an AM-FM (AM-FM) signal, its theory and methods for parameter estimation method usually include energy separation based Cyclostationarity methods and methods based on differential equations. Essence of the energy separation is to define a nonlinear signal operator (energy operator), it acts on the AM-FM signal, resulting in the energy function of the signal, they are used to the instantaneous amplitude and instantaneous frequency of the signal is estimated in the literature gives a statistic energy function additive noise. This method requires the use of discrete-time Teager-Kaiser energy function of AM and FM information in discrete time AM-FM signal is extracted, and the corresponding filter Group to digital implementation, which is a problem to be solved，furthermore, this method is just suit for single component.

Cyclostationary polynomial method is the use of reduced-order thinking, the polynomial phase signal (AM-FM signal) in the time domain with time-varying amplitude harmonic process becomes lag (A domain) with a time constant amplitude, so you can use solving harmonic retrieval method to get "harmonic amplitude", thus further AM-FM signal to make estimates. However, this method under consideration in the case of additive noise, modeling the signal is more complex, multi-component signal is even more difficult to operate.

In contrast, the method of difference equations can be used for multi-component AM-FM signal analysis. It is an AM-FM signal using a differential equation to describe, if the initial value of the differential equation pole coefficient and the characteristic equation can be informed, then the instantaneous frequency and instantaneous amplitude of the signal can be calculated. In practice, however, is not usually possible to know in advance the coefficient of difference equations. There are methods used to estimate the coefficients of the differential equation, but the application of it is very complicated.

Fractional Fourier transform is considered to be a time-frequency analysis method for the analysis of certain non-stationary signals (like LFM signal) has a very good performance, especially in that it has a linear characteristic can be easily used for multi-component LFM signal detection and parameter estimation, without cross-interference term, have been used constant amplitude chirp signals, and achieved good results. However, in many engineering applications, the use of time-varying amplitude LFM signal as a model more in line with actual engineering. Therefore, this work on the basis of this estimation problem revolves around some useful attempts were made based on the detection and parameter fractional Fourier transform variable amplitude chirp signal.

2 Time-varying amplitude chirp signal detection and estimation based on FRFT

The concept of fractional Fourier transform was first proposed by the V Namias, it can be comprehended as the generalized Fourier transform, and it can be interpreted as a signal of the axes in the time-frequency plane rotated counterclockwise about the origin as well. If the signal is an integer multiple of the rotation understood as a Fourier transform to the signal $x(t)$ from the time axis (time domain) counterclockwise rotation angle $\pi/2$ to the frequency axis (frequency domain), thus, is understood to mean any angle α except for integral times of $\pi/2$ FRFT obtained in the fractional Fourier domain (domain u) representation. It is defined as

$$X_p(u) = \{F^p[x(t)]\}(u) = \int_{-\infty}^{+\infty} x(t)K_p(t,u)dt \tag{1}$$

Where $K_p(t,u)$ is kernel function of FRFT, which is expressed as

$$K_p(t,u) = \begin{cases} \sqrt{\dfrac{1-j\cot\alpha}{2\pi}}\exp\left(j\dfrac{t2+u2}{2}\cot\alpha - jut\csc\alpha\right) & \alpha \neq n\pi \\ \delta(t-u) & \alpha=2\mathrm{n}\pi \\ \delta(t+u) & \alpha=2(n+1)\pi \end{cases} \tag{2}$$

Where p is the FRFT order, α is rotational angle and $\alpha = p\pi/2$.

A single component chirp signal with time-varying amplitude polluted by noise can be expressed as

$$\begin{aligned} x(t) &= s(t) + w(t) \\ &= a(t)\exp(j\varphi_0 + j2\pi f_0 t + j\pi\mu_0 t^2) + w(t), \ -T/2 \le t \le T/2 \end{aligned} \tag{3}$$

Where, $a(t)$ is a function of time, φ_0 , f_0 , and μ_0 is unknown initial phase, initial frequency and chirp rate of the chirp signal, E is an unknown parameter, $w(t)$ is the additive white Gaussian noise.

Wigner-Ville distribution of signal is considered to be the distribution of energy in the whole plane of the signal, which is defined as:

$$W(t,f)=\int x(t+\frac{\tau}{2})x^{*}(t-\frac{\tau}{2})e^{-j2\pi f\tau}d\tau \tag{3}$$

According to its edge characteristics, we known that the projection of WVD on the time axis represents the instantaneous energy $|x(t)|^2$ of signal, the projection on frequency axis represents the spectral density $|X(\omega)|^2$ of signal. As we extend the definition of signal into FRFT domain, then, we can get the projection of WVD in the u axis as:

$$P(u,\alpha)=\int_{L}W(t,f)dv \tag{4}$$

Where L is a straight line perpendicular with FRFT domain u , and it can be expressed as $f=kt+b$, $k=-\cot\alpha$, $b=u\csc\alpha$, and substituting it into formula (4) ,then we can get:

$$P(u,\alpha)=\int_{L}W(t,f)\int_{-\infty}^{+\infty}\delta(u'-u)dv'du'=\frac{1}{|\sin\alpha|}\left|\int x(t)e^{j2\pi(ut\csc\alpha+\frac{1}{2}t^2\cot\alpha)}dt\right|^2 \tag{5}$$

The square module for FRFT of the signal is

$$|X_p(u)|^2=|A_\alpha|^2\cdot\left|e^{ju^2\cot\alpha}\right|^2\cdot\left|\int x(t)e^{-j(ut\csc\alpha+\frac{1}{2}t^2\cot\alpha)}dt\right|^2=\frac{1}{|\sin\alpha|}\left|\int x(t)\cdot e^{-j(ut\csc\alpha+\frac{1}{2}t^2\cot\alpha)}dt\right|^2,\ \alpha\neq n\pi \tag{6}$$

Therefore, the projection of signal's WVD in FRFT domain is equals to module square of the signal's FRFT. When the signal is a chirp signal, it presents an oblique line dorsal fin distribution of its WVD in WVD plane. Chirp signal can generate energy concentration phenomenon only in the FRFT domain which is plumb with its time-frequency distribution. However, the white noise energy is evenly distributed over the entire time-frequency plane, and it will not gather energy in any FRFT domain as well.

With this obvious character, we can achieve the formula of chirp signal detection and parameter estimation as

$$\begin{cases}\hat{\mu}_0=-\cot\hat{\alpha}_0\\ \hat{f}_0=\hat{\mu}_0\csc\hat{\alpha}_0\\ \hat{\varphi}_0=\arg\left[\dfrac{X_{\hat{\alpha}_0}(\hat{u}_0)}{A_{\hat{\alpha}_0}e^{j\pi\hat{u}_0^2\cot\hat{\alpha}_0}}\right]\\ A_{\hat{\alpha}_0}=\sqrt{\dfrac{1-j\cot\hat{\alpha}_0}{2\pi}}\end{cases} \tag{7}$$

Where $\hat{\mu}_0$, $\hat{f}_0$, $\hat{\varphi}_0$ is the estimation value of μ_0 , f_0 and φ_0 respectively, and the estimated amplitude expression of chirp signal is shown as

$$\hat{a}(t)=\mathrm{Re}\left\{x(t)\cdot\exp[-j(\hat{\varphi}_0+2\pi\hat{f}_0t+\pi\hat{\mu}_0t^2)]\right\} \tag{8}$$

3 Simulation

In order to investigate the performance of parameter estimation, this gives the above algorithm Monte Carlo simulation. Simulation experiments were investigated using FRFT random variation of the amplitude and the chirp signal parameters change according to the law of the Gaussian function estimation performance, and were compared with constant amplitude, signal model is:

$$x(t)=a(t)\exp(j0.1t+j0.01t^2)+w(t) \tag{9}$$

Where $w(t)$ is additive white noise with zero mean, $a(t)$ is the amplitude of the signal.

The setting SNR range is from -2dB to 24dB, and the step is 2dB. We do 100 times Monte Carlo simulation, the mean square error curves of the estimated chirp rate value and the estimated initial frequency value (MSE(μ_0) and MSE(f_0))are shown in figure 1.

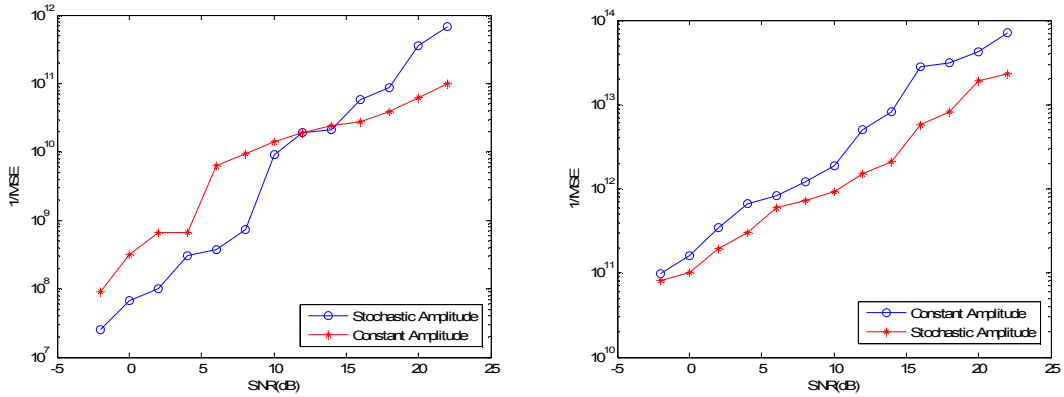

Fig1 Mean square error curves under different amplitude conditions of initial frequency and chirp rate

4 Results analysis

Simulation results from the foregoing, it can be seen: () a detection accuracy (both Reciprocal square error) with improved signal to noise ratio increases, indicating that changes in trend Potential is reasonable, FRFT can be used for time-varying amplitude linear FM signal Detection and parameter estimation. (2) the magnitude of random variation detection signal Compared with constant amplitude accuracy declined. This may be due to the amplitude Changes make signal changes in the spectral structure rather FRFD guide Cause. Inspection (3) the magnitude of change with Gaussian linear FM signal Compared with constant amplitude measurement accuracy declined, but with the amplitude attenuation factor Sub a, the increase is reduced. This is probably because the increase of al, The signal in the time domain is equivalent to the support area narrowed in the fractional Fourier Domain broadening, energy aggregation caused by deterioration.

5 Summary

This paper analyzes the general method of time-varying parameter estimates of the magnitude of the chirp signal, and then based on the parameters FRFT varying estimates of the magnitude of the problem of linear FM signal for a more in-depth research, study the detection and parameter estimation method to the results of the simulation parameter estimation performance, parameter changes and the magnitude of random Gaussian function varies with the chirp signal estimation mean square error. Theory and simulation show that, FRFT for the detection of varying amplitude linear FM signal is a convenient and effective tool.

Keywords: DS/FH hybrid spread spectrum signal, interference, measurement performance

Abstract. The measurement performance with the interference is presented with the new DS/FH hybrid spread spectrum signal system. The DS/FH system model is established. The change of the SNR ratio is obtained by analyzing the characteristics of three kinds of interference signal such as partial-band noise jamming(PBNJ), wide-band noise jamming(WBNJ) and additive white Gaussian noise(AWGN). Then the ranging and velocity measurement performance is got through the simulation.

Introduction

With the continuous development of interference, the challenge facing the monitoring system is also growing [1-2]. It is a vital topic of ensure effective monitoring and control in harsh interference environments, which will be the future development trend of monitoring system. The proposed DS/FH hybrid spread spectrum monitoring system is to solve the interference in harsh conditions and effective monitoring and control [3-4]. It combines the advantages of DS and FH spread in two ways, capable of making the measurement and control system has a strong anti-jamming and interception capabilities.

1 System model

Send and receiver DS / FH hybrid spread spectrum system block diagram shown in Figure 1 and Figure 2, BPSK modulation input information, and then to DS and FH spread spectrum spreading processing. At the receiver, the transmitted signal by the blocking of broadband interference effects of partial-band interference and white Gaussian noise. Despreading processing of the useful signal is equivalent to the process of the interference signal and a Gaussian white noise FH and DS spreading.

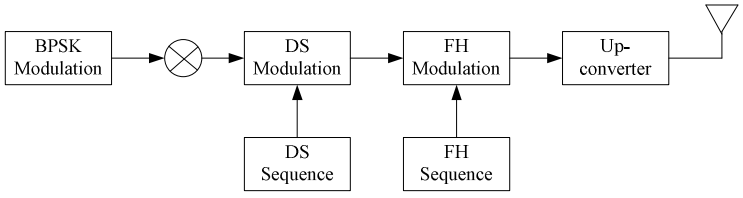

Fig1 Sending signal schematic diagram of DS/FH Hybrid Spread Spectrum Systems

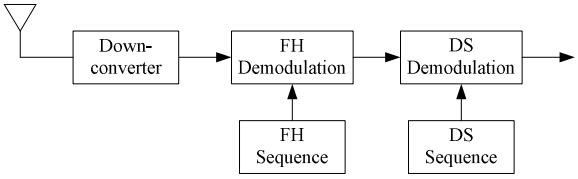

Fig2 Receiver block diagram of DS/FH hybrid spread spectrum system

2 SNR analysis

The signal jump after de-spreading and demodulating hopping process, the l th interval of the frequency hopping of the received signal after processed can be described as [5]:

$$r_l(t) = s_i(t) + n_l(t) + j_{\omega l}(t) + j_{pl}(t),\ (l-1)T_h \le t \le lT_h \tag{1}$$

$s(t)$ is the useful signal, $n_1(t)$ to be processed after the AWGN (White Gaussian Noise) signal, $j_{\omega l}(t)$ to be processed after the blocking wideband interference, $j_{pl}(t)$ is carried out after processing the sub-band interference. The useful signal is represented as:

$$s_i(t) = \sqrt{2E_b R_b}\cos(2\pi f_0 t + j\pi),\ j = 0,1 \tag{2}$$

E_b is the bit energy, f_0 is the frequency of the baseband useful signal. Due to the characteristics of the PN sequence spread spectrum signal, and therefore it does not produce anything during the time of the spreading influence of AWGN, so $n_1(t)$ can be considered zero mean and power spectral density N_0(W/ Hz). For broadband obstruction interference, assuming that its energy is J, the RF signal bandwidth of W_{ss}, you can think of it as a mean of 0, the power spectral density of $N_J = J / W_{ss}(W / Hz)$, for some band interference, assuming that the ratio of the interference band is $\eta = W_J / W_{ss}$, then it can be considered mean 0, power spectral density $N_J' = J / (W_J) = (J / W_{ss}) \cdot (W_{ss} / W_J) = N_J / \eta\ (W / Hz)$, Since the DS/FH hybrid spread spectrum system itself anti-jamming performance, so the baseband interference power output is reduced G_p times, so broadband blocking interference power spectral density after treatment for $N_{WJ} = J / (W_{ss} G_p) = N_J / G_P (W / Hz)$, part of the deal after the band interference power spectral density $N_{Pl} = N_J / (\eta G_p)\ (W / Hz)$, suppose that the parameters a, when $a = 1$, said first l hop interference, whereas when $a = 0$ is not disturbed. In summary, the equivalent system after processing the interference power spectral density is:

$$N_J = N_0 = \frac{N_J}{G_P} + a_l \frac{N_J}{\eta G_P},\ l = 1,2,...,L \tag{3}$$

So, we get the carrier to noise ratio of the system is

$$\frac{C}{N_0} = \frac{2E_b}{\frac{1}{L}\sum_{l=1}^{L} N_l} = \frac{2E_b}{N_0} \cdot \frac{1}{1 + \frac{JNR}{G_P} + \frac{k}{L}\frac{JNR}{G_P \eta}} \tag{4}$$

Where, $JNR = N_J / N_0$, a total of k jump is affected.

3 Ranging speed performance analysis

In order to determine the performance of different measurement loops must be analyzed carrier tracking loop (PLL) and delay locked loop tracking code (DLL) tracking performance. Since the receiver is nonlinear, the Monte Carlo simulator can be used to determine the circumstances under various stress factors expected to track the performance of the receiver, you can also determine the code and carrier tracking performance through a number of rules of thumb. We use rules of thumb to determine the spreading code and carrier tracking performance.

3.1 carrier tracking loop

Analysis of frequency locked loop with phase-locked loop, like locked loop can be directly read out copy of the carrier frequency, and thus deduce the receiver Doppler shift. PLL and the like, the total phase locked loop jitter variance are $\sigma_i = \sqrt{\sigma_{tFLL}^2 + \sigma_V^2 + \sigma_A^2}$, σ_{tLL} caused by the thermal noise of the frequency jitter. σ_V and σ_A are dynamic stress error, frequency error because the dynamic stresses induced jitter is relatively small, so the actual analysis time can be negligible.

Consider the tracking error of the measurement accuracy under the influence, regardless of each order loop, the loop order of the thermal noise, thermal noise variance are:

$$\sigma_{tFLL} = \frac{1}{2\pi T_{coh}}\left[\frac{4FB_L}{C/N_0}\left(1 + \frac{1}{T_{coh} C/N_0}\right)\right]^{1/2} \tag{5}$$

Where, B_L is loop bandwidth, C/N_0 is the carrier to noise ratio, T_{coh} is pre integral time, where the parameter F is set to 1, when C/N_0 is a higher value, otherwise F is set as 2.

Setting $F=1$, and then substituting formula(4) into formula (5), we can get:

$$\sigma_{tFLL}=\frac{1}{2\pi T_{coh}}\left[\frac{4FB_L}{C/N_0}(1+\frac{1}{T_{coh}C/N_0})\right]^{1/2}=\frac{1}{2\pi T_{coh}}\left[\frac{4B_L(1+\frac{JNR}{G_P}+\frac{k}{L}\frac{JNR}{G_P\eta})}{\frac{2E_b}{N_0}}\left(1+\frac{1+\frac{JNR}{G_P}+\frac{k}{L}\frac{JNR}{G_P\eta}}{T_{coh}\frac{2E_b}{N_0}}\right)\right]^{1/2} \quad (6)$$

Taken during the simulation loop bandwidth of 18 Hz, it can be deduced by the foregoing, the frequency curve of the jitter variance were affected to the number k of the frequency hopping shown in Figure 3.

As the carrier measurement accuracy can reach $\Delta f=\sigma_{tFLL}/T$, T is the Doppler integration period, then the velocity measurement accuracy is

$$\Delta v=\Delta f/f_0\cdot c=\frac{\sigma_{tFLL}\cdot c}{T\cdot f_0} \quad (7)$$

So we can know that when the carrier frequency f_0 is a certain number, the speed accuracy changes with σ_{tFLL}, and it is shown in Figure 3.

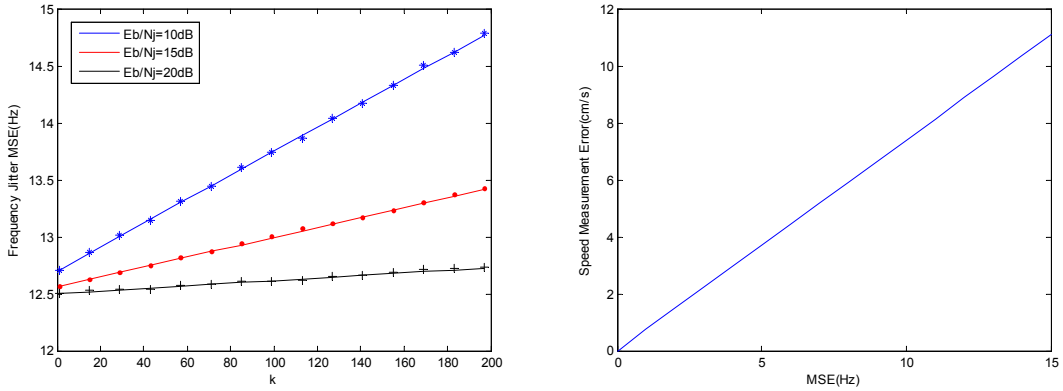

Fig3 Relationship between MSE of FLL tracking jitter variance with k and speed accuracy jitter respectively

3.2 Yards tracking delay locked loop

Receiver capture DS/FH signal, the received signal and the PN code is not fully aligned with the local code reproduced, it is necessary to further track DS/FH signal. And frequency-locked loop as an error code rings caused mainly by the thermal noise code phase jitter and dynamic stress error in two parts, regardless of the circumstances under dynamic stress of thermal noise tracking error jitter as

$$\sigma_{tDLL}=\left[\frac{dB_L}{2C/N_0}\left(1+\frac{1}{T_{coh}C/N_0}\right)\right]^{1/2} \quad (8)$$

Where, B_L is the loop bandwidth, C/N_0 is ratio of the carrier to noise, T_{coh} is pre integral time, D is the space between the former correlator with the later (generally taken to be 1).

As the same processing as the above, we can get:

$$\sigma_{tFLL}=\left[\frac{dB_L}{2C/N_0}(1+\frac{1}{T_{coh}C/N_0})\right]^{1/2}=\left[\frac{B_L(1+\frac{JNR}{G_P}+\frac{k}{L}\frac{JNR}{G_P\eta})}{\frac{4E_b}{N_0}}\left(1+\frac{1+\frac{JNR}{G_P}+\frac{k}{L}\frac{JNR}{G_P\eta}}{T_{coh}\frac{2E_b}{N_0}}\right)\right]^{1/2} \quad (9)$$

Similarly, the loop bandwidth is taken during simulation of 18Hz, the jitter can be obtained curves are affected by the variance of the number k of the frequency hopping shown in Figure 4.

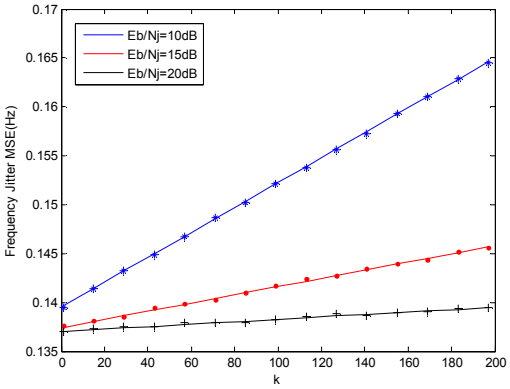

Fig4 Relationship with delay interval, code sequence and likelihood value

Chip tracking accuracy can be achieved $\Delta\tau = \frac{\sigma_{tDLL} \cdot T_c}{180^\circ}$, T_c is a chip period, the accuracy of distance measurements is

$$\Delta s = \Delta\tau \cdot c = \frac{\sigma_{tDLL} \cdot T_c \cdot c}{\pi} \tag{10}$$

So you can learn at the carrier frequency f_0 certain circumstances, with the change of σ_{tFLL}, the speed accuracy is also followed changes in trends and a similar effect on the measurement precision σ_{tFLL} is generated.

Summary

In this paper, the DS/FH hybrid spread spectrum signal speed ranging performance under interference conditions, through theoretical analysis and simulation shows that under the new system, and DLL FLL tracking loop jitter variance with both the number of interference by hopping points characteristics change, but also analyzes the impact velocity tracking jitter variance ranging performance are generated. After further study of DS / FH hybrid spread spectrum signal provides a foundation in the Satellite Control System.

Research of Image Denoising Method about Wavelet Transform with Neighborhood Average

Chen Huang

Department of Electrical Engineering, Guidaojiaotong Polytechnic Institute, Shenyang 110023, China

Email: huangchen054@163.com

Keywords: Wavelet transform, Neighborhood average filtering, Image denoising

Abstract. Because wavelet transform has good time-frequency characteristics, and its application in image denoising has been promising. Firstly, use the threshold method of the wavelet transform is used in removing image noise, and then the denoised image is smoothed using neighborhood average filtering with Gauss template. And wavelet denoising process and domain threshold selection principle are discussed. Simulation results show that this method can effectively reduce the noise and can remain most of image details better.

Introduction

The image denoising is very important for image processing, and the whole process of image with noise affects the image processing of the input, collection, processing and the output of the results. If there is too more input noise, the process and output results will be inevitably affected. So it is necessary to remove the image noise, lower noise affect, improve signal -noise ration.

Wavelet method characteristic has high frequency resolution and low time resolution in the low frequency part and has high time resolution and low frequency resolution in the high frequency part. Wavelet transform technique has unique time-frequency localization characteristic, so it has obvious advantages over the traditional denoising in discerning noise signal and image noise and effectively removing the noise and retaining useful information. It is well known that the wavelet denoising is superior. At the same time, wavelet denoising has certain limitations, and the better result can be obtained by neighborhood average filter to eliminate the sharp sense of denoised image.

Wavelet transform denoising principle

It is one of important applications that two-dimensional signal denoising for wavelet transform. The image is one kind of two-dimensional (2D) signal, and 2D multi-resolution is similar to one-dimensional signal. However, let the 2D space function be $L^2(R)$， and the scale function be $\varphi(x,y)$.

Let $\{V_j\}_{j\in Z}$ is a multi-resolution analysis of $\{V_j\}_{j\in Z}$, then it can be shown that tensor space $\{V_j^2\}_{j\in Z}$: $V_j^2 = V_j \oplus V_j$ compose a multi-resolution analysis of $L^2(R*R)$, Two dimensional scaling function $\varphi(x,y)$ is:

$$\varphi(x,y) = \varphi(x)\varphi(y) \tag{1}$$

Equation (1) shows the separability of two-dimensional scaling function. For each $j \in Z$, Function system $\{\varphi_{j,n,m}(x,y) = \varphi_{j,n}(x)\varphi_{j,m}(y) \,|\, (n,m) \in Z^2\}$, it constructs orthonormal basis.

$$\varphi_{j,n,m}(x,y) = 2^j \varphi(x - 2^j n)\varphi(y - 2^j m), (j \geq 0) \tag{2}$$

If $\psi(x)$ is one dimensional multi resolution analysis, the three wavelet function for two-dimensional multi-resolution analysis is formulated as follows:

$$\psi^1(x,y)=\varphi(x)\psi(y)$$
$$\psi^2(x,y)=\psi(x)\varphi(y) \quad (3)$$
$$\psi^3(x,y)=\psi(x)\psi(y)$$

Where $\psi(x)$ and $\psi(y)$ are $\varphi(x)$ and $\varphi(y)$ corresponding orthogonal wavelet functions respectively.

For each $j\in Z$, the integer translation system as follows:

$$\psi^1{}_{j,n,m}(x,y)=\varphi_{j,n}(x)\psi_{j,m}(y)$$
$$\psi^2{}_{j,n,m}(x,y)=\psi_{j,n}(x)\varphi_{j,m}(y) \quad (4)$$
$$\psi^3{}_{j,n,m}(x,y)=\psi_{j,n}(x)\psi_{j,m}(y)$$

Function system $\{\psi^{\varepsilon}{}_{j,n,m}(x,y)\}=\{2^j\psi^{\varepsilon}(x-2^jn,y-2^jm\}$, $j\geq 0,\varepsilon=1,2,3$ is $L^2(R*R)$ orthonormal basis, ε =1,2,3 is corresponding to three directions in the horizontal, vertical and diagonal.

For a two-dimensional image signal $f(x,y)\in L^2(R*R)$, in resolution 2^{-j} conditions, there is the following equation:

$$D^1{}_jf=\left\langle f(x,y),\psi^1{}_{j,n,m}(x,y)\right\rangle,(n,m)\in Z^2$$
$$D^2{}_jf=\left\langle f(x,y),\psi^2{}_{j,n,m}(x,y)\right\rangle,(n,m)\in Z^2 \quad (5)$$
$$D^3{}_jf=\left\langle f(x,y),\psi^3{}_{j,n,m}(x,y)\right\rangle,(n,m)\in Z^2$$

Wavelet threshold method is classical and general. The basic idea of wavelet threshold denoising is as follows:

(1) The signal $f(k)$ with noise is disposed with wavelet transform, and a set of wavelet coefficients $W_{j,k}$ are obtained;

(2) With the threshold processing for $W_{j,k}$, the estimated coefficient $\hat{W}_{j,k}$ is got to make the difference between $W_{j,k}$ and $\hat{W}_{j,k}$ be as small as possible;

(3) Using $\hat{W}_{j,k}$ wavelet reconstruction, we can get the estimation signal $f(k)$, which is the denoising signal.

Neighborhood average filtering

Neighborhood average method is a kind of image smoothing method using Box templates for the operation of the image, and Box template is a template in which all coefficients are the same values of the template. The template commonly used 3 × 3 template or 5 × 5 template. Box template does average processing for the current pixel and its neighboring pixels, so that it can filter out more noise in the image. The idea of smoothing template is based on that averaging one point and the 8 points around the point, thereby removing the sudden changes and filtering out the noise. As shown in Equation (6), let $f(i,j)$ be a given noisy image and $g(i,j)$ be the renoised image after neighborhood average filtering.

$$g(i,j)=\frac{\sum f(i,j)}{N},(i,j)\in M \quad (6)$$

Where M is the coordinate of the adjacent pixels in the neighborhood and N is the number of adjacent pixels contained in the neighborhood.

However, the image has a certain degree of ambiguity. While considering the points in the neighborhood, do not consider the impact of the 9 points location, and smoothing effect is not ideal. In fact we can introduce weighted coefficient, and form the new template called Gauss Template. This template is a common smooth template. This template is obtained by sampling 2 dimensional Gauss function. Use Gauss template to achieve the smoothing effect clearly. Therefore, we use the 3 × 3 Gauss template. In order to keep the average value of the smoothing image unchanged, the elements' sum is 1 within this template.

Filtering simulation and analysis

In this paper, MATLAB is used for simulation. Firstly, we could analysis the threshold effect of wavelet transform. Fig. 1 is the original signal and the noisy signal, and Fig.2 is the effect of four threshold methods selected for image denoising. In the process, the hard threshold function is used. As can be seen from Fig. 2, the denoising effect of sqtwolog and heursure is more thoroughly. And because rigrsure and minimaxi threshold rules are very conservative, and the noise cannot be completely removed, but in the high frequency and the weak signal can be separated from noise.

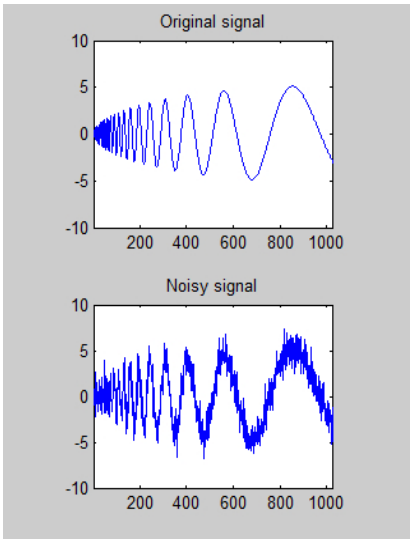

Fig. 1 The original signal and the noisy signal

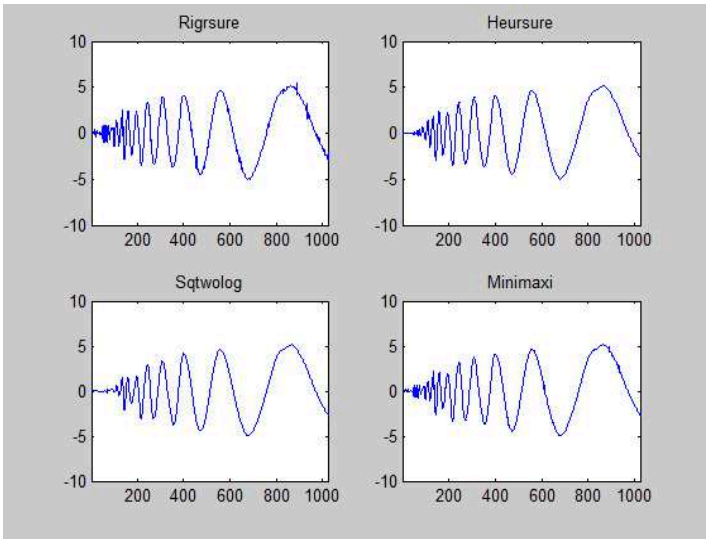

Fig. 2 The four threshold method of wavelet transform

According to the above analysis, in this paper the heursure method of wavelet threshold selection is used to remove the image noise. Choose figure 3 as the simulation object. First, add the random noise to the original image, as illustrated by Fig. 4. Secondly, using wavelet change to remove the image noise, as has been found that the result is not very ideal by Fig. 5.

Fig.3 Original image

Fig.4 Noisy image

Fig.5 Wavelet transform

In the second step, the neighborhood average with Gauss template is used to achieve image smoothing after denoising, and SNR is 30dB, as shown in Fig. 6 (d). At the same time, compare the different combination filtering method, Fig. 6 (a) shows the result of dual wavelet transform, (b)

shows the result of the mean filter and wavelet, (c) shows the result of the Wiener and wavelet, (d) shows the result of the neighborhood average and wavelet. According to Fig. 6, this method in this paper has certain advantages.

(a) (b) (c) (d)

Fig.6 Comparing results of various combination renoising methods

Summary

From the experimental results, the denoising effect of wavelet transform and neighborhood average described in this paper is much better, and it has strong adaptability and it is simple. Use wavelet transform and neighborhood average for denoising and it can maintain some image edge details. But there are still some shortcomings, therefore need further improvement for obtaining better effect.

Application and Debugging of All-digital Frequency Synthesizer

Hanbai Fan, Xian Meng, Junma Hou

North China Electric Power University, Baoding 071003,China

Keywords: SCM, Si4133, frequency synthesizer, Phase-Locked Loop.

Abstract: Presents the working principle of Integrated PLL chip Si4133, this paper presents the implementation of a 375MHz local oscillator for a super heterodyne transmitter/receiver by using Si4133.Using programming method to set the divider register Internal chip. In addition, this paper discuss the methods for decreases the phase noise. Debugging circuit using ICCAVR software , and show the debugging results. Facts show that the phase noise and spurious of the frequency synthesizer is low, and it is practical.

Introduction

Frequency synthesizer is used extremely broad in areas such as communications, radar, measurement and automation control, which has become essential basic components of various electronic devices[1]. With the development of electronic technology to digital direction, it requires digitally method to achieve the signal phase locking, so as to achieve the purpose of generating specific frequency. Traditional Phase-Locked Loop (PLL)is implemented by analog circuit. Digital Phase Locked Loop (DPLL) is high precision and not affected by voltage and temperature, compared to traditional analog circuit PLL. The loop bandwidth and center frequency is programmable .It's easy to build higher-order phase-locked loop. And more then when it is used in digital systems , with no need of A / D and D / A converter[2-4]. With the rapid development of communication technology, integrated circuit technology and system-chip (SOC) in-depth study, all-digital frequency synthesizer is bound to be more widely used.

Si4133 is production of Silicon Laboratories .It is an American company. Si4133 Contains an internal voltage controlled oscillators (VCO), loop filters, phase detectors, frequency dividers and other components. with only a small number of external components, it can constitute a PLL, which is the digital frequency synthesizer core. Figure 1 is the schematic diagram of Si4133. Two RF optimal center frequency of the VCO is between 947MHz ~ 1720MHz and 789MHz ~ 952MHz; IF center frequency of the VCO is 526MHz ~ 952MHz, can be achieved the minimum 62.5MHz by dividing.

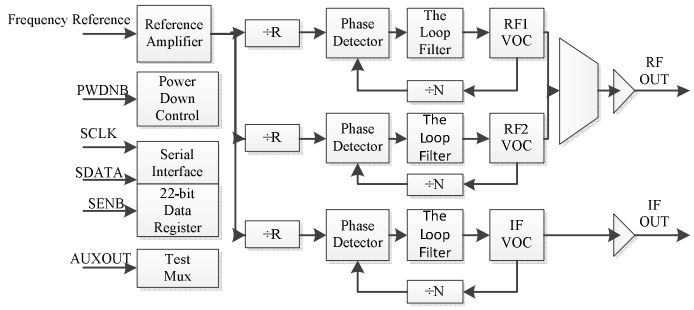

Fig.1 Block diagram of Si4133

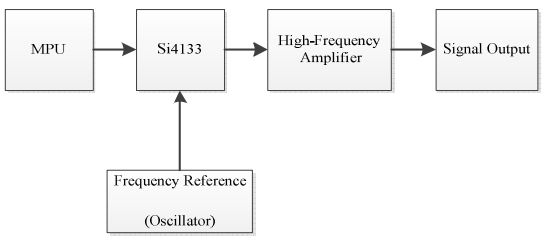

Fig.2 The overall circuit diagram

The chip has been widely used in electronic communications, GSM dual-band mobile phone and so on. This paper is used of Si4133 to design a frequency synthesizer to generate 375MHz frequency, as a super heterodyne transmitter / receiver local oscillator.

The overall design

Figure 2 is the overall circuit block diagram of the frequency synthesizer, the arrows represent flow of signals . We use AVR microcontroller. In this circuit we choose ATmage8. Compared to other 8bit MCU, the AVR has many advantages such as high computing speed, small object code, abundant internal resources, and so on[5]. The using of AVR can greatly improve the efficiency of debugging. AVR microcontroller sends out Control signals, to change the center frequency of the output signal of Si4133; This design uses 12.8MHz active high stability crystal oscillator as frequency reference source; The output signal through the Si4133 IF pin must be coupled to the next stage through a capacitor, that is, a high-frequency amplifier. After signal amplification, the signal can be obtained as the frequency synthesizer output signal. Finally, the signal through an coupling capacitor to the load.

In this frequency synthesizer, we use the Si4133 IF VCO generates a signal of 750MHz, then after frequency divider of the two obtained the 375MHz signal. Figure 3 is the interface circuit of Si4133. The 15 feet XIN connect oscillator frequency input. The 22 feet is the IF output terminal IFOUT.Si4133 via 1 feet SCLK (clock), 2 feet SDATA (data) and 24 feet SEN (Enable) the three pin connect to AVR microcontroller. It is effective when the enable terminal is low. The AVR microcontroller write the Internal registers of Si4133 through serial communication. A bit of data latched at each clock rising edge, and write into registers of Si4133 at falling edge of the clock. The AVR microcontroller writing data from the highest bit of register to the lowest bit of register. It is easy to change the frequency of the output signal. By setting 14 feet PWDN level and control relevant internal registers, you can set the low-power operating mode and choose the circuit that you need to work. The 13 feet AUXOUT can be output signal. When the pin is low , the output frequency is lock-lose. L2 in the Figure is the external inductor for Si4133, which ranges from 2.2nH ~ 12.0nH. It is primarily used to set the center frequency of the VCO output signal.

By the upper, it is can be seen that the digital frequency synthesizer design with Si4133 is easy to operate. Its external circuit is relatively simple. It can easily change the frequency of the output signal. So it is a practical frequency synthesizer.

2 Debugging and Implementation

Set the center frequency of VCO. Si4133 center frequency of the VCO output signal depends on the external connection inductor value. Taking into account the 10% error of an external inductor, Si4133 can be self-adjusting algorithm for compensating inductor error. Because the magnitude of the inductor value is nH, the packaging issues should be considered when determining the inductor value. Figure 4 is VCO connection with an external inductor. L_{PKG} is inside inductor of the package. L_{EXG} is external inductor; L_{LOT} is the sum of external inductance L_{PKG} and package inductance L_{EXG}. Si4133 VCO center frequency is calculated as:

$$f_{CEN} = \frac{1}{2\pi\sqrt{(L_{PKG} + L_{EXT}) \bullet C_{NOM}}} \tag{1}$$

The L_{PKG} of IF VCO is 2.1nH,the C_{NOM} is 6.5pF.We demand the frequency output of the IF VCO is 750MHz. Substituted into the formula (1) calculation shows L_{EXT} = 4.828nH, since the actual ,there is no such exact inductance. We chose the labeled value of 4.7nH wire-wound high Q values inductor, which can be calculated the center frequency is 757MHz.

Si4133 has sixteen 22 bits data registers, which comprises 18 bits data code and the 4 bits address code. registers 0 to 8 are programmable, they are : Main Configuration, Phase Detector Gain, Power Down, RF1 N-Divider, RF2 N-Divider, IF N-Divider, RF1 R-Divider, RF2 R-Divider, IF R-Divider. Register 9 to 15 is reserved. It set the division ratio and the frequency of RF VOC or IF VOC to obtain the final needed frequency. You can control the gain of the phase detector (also called phase sensitive). VCO gain and the LF gain can't set by programming. Unused registers are written to 0x00.

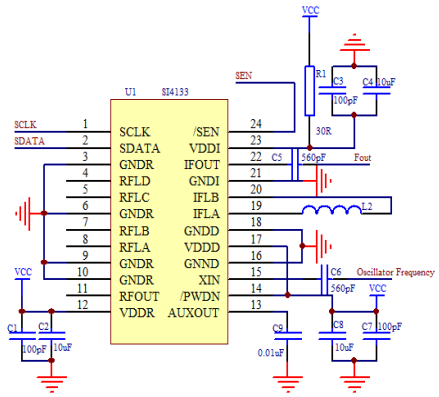

Fig.3 The Interface circuit of Si4133

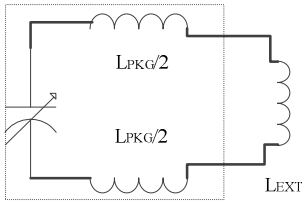

Fig.4 VCO connection with external inductor

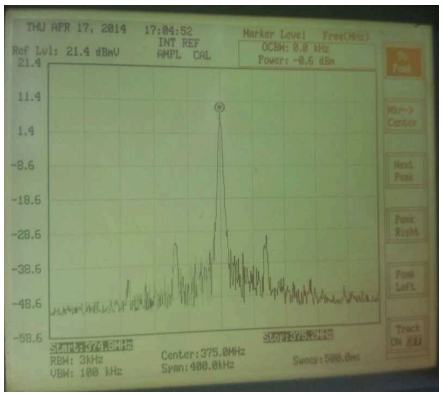

Fig.5 Test result

By setting R-Divider register and N-Divider register resulting output frequency is:

$$f_{OUT} = Nf_{IN} / R \quad (2)$$

f_{OUT} is the frequency output of the VCO. f_{IN} is frequency reference input the XIN pin. The reference frequency signal after R-Divider is f_{IN}/R. The VCO output signal after N-Divider is f_{OUT}/N. The two signals phase comparison in the PD, continuously control and correction, until both phases are identical, then the loop is locked when the output frequency is the setting value.

Tab.1 The set frequency compare with the actual frequency

Set frequency /MHz	The difference from center frequency (757)/MHz	The actual output frequency /MHz
710	-47	708.5562
720	-37	719.9981
730	-27	730.0015
750	-7	750.0013
770	13	769.9983
790	33	789.9978
800	43	798.6782

We use the digital oscilloscope observation frequency synthesizer output signal; the results are shown in Table 1. The set frequency comparison between the actual output frequency. When the center frequency is set to 757MHz, the set frequency is 720MHz, 730MHz, 750MHz, 770MHz, 790MHz, the error of the actual output frequency within ± 2KHz, within an acceptable error range. But in the 710MHz and 800MHz error increased significantly, phase-locked loop lost lock. Visible when setting the value of frequency adjustment doesn't exceed ± 5% of the center frequency, the frequency of output signal is accuracy. When the center frequency is set to 750MHz, it is accuracy, and then divides by 2, we can get an accurate 375MHz output signal.

The debugging of chip lock will come across some troubles ,which are caused by the problems of the parameters of peripheral devices or the Program. We found some rules, for example, the R-Divider register and N-Divider are not designed casually if we want to get the numerical value calculated by the formula (2), sometimes there will be some deviations. So we should choose some more data for testing and observing, and then select a group of optimal value.

The Control of phase noise. When design the PLL frequency synthesizer, we should consider the phase noise of the circuit to achieve the index, and eliminate the effects of phase noise. In general, the phase noise of loop in-band is determined by the noise of phase detector，divider and oscillator，and the out-band phase noise is mainly determined by VCO[6]. For the phase noise of crystal reference source, R divider, phase detector, N divider, their transfer function is low pass form. And for VCO, the phase noise form of transfer function is high-pass form. So the total output

phase noise is the sum of the product of noise source phase noise and their respective transfer function. In addition, we should consider that the loop bandwidth affects the noise within the band of loop a lot. So if the loop bandwidth is too narrow, the within band noise of VCO will not be ignored. But if it too wide, it could cause the deterioration of out-of-band noise.

Against the problem of phase noise, we adopted a series of measures to control .First of all, we choose a 12.8 MHz active TCXO as frequency reference source, whose frequency stability within the working temperature can reach ±0.5ppm, phase noise can be -100dBc/ Hz @100 Hz; We choose high Q value wire-wound inductance as the external inductance; Phase discriminator gain is not the bigger the better, we should set up it according to the size of the divider register. These measures can reduce the phase noise of the signal source greatly.

In addition, we adopt Gali-3+ which is a broadband high frequency amplifier as the last level of the frequency synthesizer. Its amplification at 375 MHZ can reach 17.5 dB ~ 22.4 dB, so that it can restrain low frequency noise well, and also increase the power of signal output.

Test Result

Figure 5 is the test result using the spectrum analyzer to test the finished circuit. When we set the update frequency (f_{IN}/R) 50KHz. We can obviously seeing in the test, there is some spurious frequency which stray away from the center frequency at 50kHz. When IF locked loop output signal is 375MHz,the power can reach-0.6dBm,the phase noise at 100kHz offset is -85dBc/Hz @ 100KHz.It can satisfy the receiver/ transmitter needs of the local oscillator.

Conclusion

The all-digital frequency synthesizer whose core is Si4133 can be designed simply. The frequency of output can be controlled by software, with the advantage of easy operational, low phase noise, low spurious, and very practical.

Keywords: Electronic satellite; heuristic algorithm; scheduling strategy; hierarchical optimization; roulette; TOPSIS

Abstract. The problem of scheduling for electronic satellites is a serious problem involving a lot of complex constraints. Considering the specific constraints of electromagnetic detection electronic satellite, on the basis of rational hypothesis, a multi-objective mathematic model was established. Several basic scheduling strategies were proposed. Based on the roulette method and hierarchical optimization method, a heuristic algorithm based on the rules was designed. A comprehensive evaluation with Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) for the algorithm was offered. Finally, some experiments are conducted to verify the correctness and practicability of our scheduling model and algorithm.

0 Introduction

Electronic satellite is an artificial earth satellite detecting electromagnetic signal of the targets in which users are interested near satellite point by spaceborne remote sensing electronic equipment when flying around the earth. It has such advantages as covering a wide area, having a long lifetime, without area and weather condition limit, no need considering the safety of personnel. The information electronic satellite collects has important significance in industrial, scientific and military field. It also has great significance to research electronic satellite scheduling problem, maximize the profit of the tasks electronic satellite completes when expanding less resource, and make full use of electronic satellite resource.

So far, the vast majority related research that can be retrieved are for imaging satellites in the field of satellite scheduling. Literature [1] established ROCSAT-Ⅱ satellite programming model and proposed Lagrangian relaxation method based on single workpiece problem, Literature [2] solved the constellation planning problem for the Cosmo-Skymed using tabu search and random greedy algorithm Literature [3] established scheduling model for regional imaging satellites, and solved it by the use of neighborhood search methods. Literature [4] studied the scheduling problem for the sea and communications satellites and proposed task scheduling algorithm. Literature [5] established multi-objective model based on constraint Satisfaction for imaging satellites scheduling and solved it using SPEA2. Literature [6] studied the satellite application task planning problems and established directed acyclic graph model. However much less literature is able to retrieve in electronic satellite scheduling field. Literature [7] studied the multiple electronic satellites scheduling problem, and adopt genetic algorithm based on dynamic penalty function for solving. Literature [8] established a multi-objective mathematical model for electronic satellite integrated planning problems.

In the premise of in-depth analysis of the relevant literature for satellite scheduling, we study the scheduling model and give out the related solving algorithm. Firstly, according to the relevant characteristics of electronic satellite scheduling problem, extract the main constraints of the problem and make some reasonable assumptions and simplified, establish a multi-objective programming mathematical model for electronic satellite scheduling problem. Then propose several basic scheduling strategy, design rule-based heuristics under the idea of hierarchical optimization and roulette. We construct the index system for scheduling objective evaluation which is done by TOPSIS method. Finally, we give out our the simulation experiments and data analysis, and algorithm

comparison results proved that the proposed method can help effectively solve the electronic satellite scheduling problem.

1 Problem Analysis

Electronic satellite scheduling problem can be described as follows: Based on considering the electronic satellite detection capabilities and user needs, allocate resources to multiple competing tasks and determine the start and end time, work mode, and other related information. The target of this problem is that, considering the relevant constraints, the total value of the tasks scheduled successfully could be maximum and the need of users could be best meet.

Electronic satellite scheduling problem is a NP-Hard problem, involving a variety of complex constraints. To consider the main features of the issue, we make the following assumptions and simplifications:

(1)We only consider the payload of satellite, without regard to the other satellite service system.

(2)Assuming each satellite contains only one sensor, we could separate the satellite carry multiple sensors into multiple satellite carry only one sensor.

(3)The targets are fixed targets, and the electromagnetic characteristic parameters and other related information has been notified in advance, the work mode of electronic payload on satellite always is default accurate measuring mode.

(4)We would not consider the limitation of satellite storage capacity. That is, satellite has enough storage capacity to complete all tasks.

(5) The Duration of each frequency band is a fixed value. The transform time between different bands is so small that it could be neglected.

2 Model

2.1 Symbol Definition

(1) t_S represents the start time of scene, t_E represents the end time of scene.

(2) I represents the collection of tasks, $TaskNo$ represents the number of tasks, LP_i represents the priority of tasks.

(3) tw_i represents the feasible time windows of task i, ws_i and we_i represent the start time and end time of tw_i respectively, dt_i represents the duration of task i, st_i represents the start time of task i.

(4) o represents the virtual start task of satellite，whose start time is a and duration is 0; d represents the virtual finish task of satellite, whose start time is b and duration is 0.

(5) x_{uv} represents the satellite would continuously carry out task u and task v,when the satellite continuously carry out task u and task v, $x_{uv}=1$， otherwise $x_{uv}=0$.

(6) w_{il} represents the satellite would collect signal for task i by frequency band l,when the target frequency of task i is in frequency band l, $w_{il}=1$,otherwise $w_{il}=0$.L represents the collection of frequency band, t_l represents the duration of each frequency band, $lUpper_i$ and $lLower_i$ represent the upper and lower of frequency band l_i respectively.

2.2 Constraints

(1)Virtual task o and virtual task d would meet the conditions, which describe the satellite is available and virtual task o and virtual task d must be performed.

$$\sum_{v\in I\cup\{d\}} x_{ov}=1 \tag{1}$$

$$\sum_{u\in I\cup\{o\}} x_{ud}=1 \tag{2}$$

(2)Each task could be performed only once by satellite, and it must meet a certain order among the tasks.

$$\sum_{v\in I\cup\{d\}} x_{uv} \le 1, \forall u \in I \tag{3}$$

(3)When a task is performed in a time window of satellite, the start time and end time of this task could not beyond this time window range.

$$x_{uv}(st_u - ws_u) \ge 0, u \in I, v \in I \cup \{d\} \tag{4}$$

$$x_{uv}(st_u + dt_u - we_u) \le 0, u \in I, v \in I \cup \{d\} \tag{5}$$

(4) Here is the decision variable ranges.

$$x_{uv} \in \{0,1\}, u \in I \cup \{o\}, v \in I \cup \{d\} \tag{6}$$

$$w_{il} \in \{0,1\}, i \in I, l \in L \tag{7}$$

$$t_S \le st_i \le t_E, \forall i \in I \tag{8}$$

2.3 Index System

The indexes of the scheduling scheme of electronic satellite mainly include profit index, timeliness index and effectiveness index.

(1) Profit Index

For different tasks, users have different degree requirements. The more important the target is, the higher the profit (priority) of the task would be. Therefore, the profit index of scheduling scheme usually is measured by the sum of priority of tasks scheduled successfully.

$$V_1 = \max : \sum_{v\in I} \sum_{u\in I\cup\{o\}-\{v\}} \{x_{uv} \bullet LP_v\} \tag{9}$$

(2) Timeliness Index

Users have certain timeliness requirements for the task completion time, so scheduling scheme should make more important task to be performed as early as possible.

$$V_2 = \max : \sum_{v\in I} \sum_{u\in I\cup\{o\}-\{v\}} \{x_{uv} \bullet (t_E - st_v) \bullet LP_v\} \tag{10}$$

(3) Effectiveness Index

Limited resources could not meet the scheduling needs of all tasks. Efficient scheduling method should make more tasks to be executed. So we reflected the effectiveness of scheduling scheme by the rate tasks are scheduled successfully. The higher the rate is, the more effective the scheduling scheme is.

$$V_3 = \max : \sum_{v\in I} \sum_{u\in I\cup\{o\}-\{v\}} x_{uv} / TaskNo \tag{11}$$

3 Rule-based Heuristic Algorithm

Satellite scheduling problem is a NP-Hard problem. Given the complexity, scale and operability, rule-based heuristic method is still the most viable and effective solution method. The advantage is that such method does not require a lot of computing, which reduced configuration requirements of computing resources in work schedule; and also avoids the combinatorial explosion problem. Once the appropriate rules are chosen, corresponding scheduling strategy can be generated, which is quite easily performed. By analyzing the characteristics of the electronic satellite scheduling problem, based on previous experience of the planning and scheduling, proposed the basic rule of electronic satellite scheduling and designed rule-based heuristic algorithm.

3.1 Deterministic Strategy

(1) OPS Strategy

Determine the order of resources allocation according to the task priority and task list order sequentially. Allocate resources as early as possible so that the scheduling task executes as soon as possible. The realization process of the strategy is simple, algorithm ideas are easy to understand and

execution speed is relatively fast, which makes it suitable for the problems of resource "oversupply" and with less task time windows overlap.

(2) SEQ Strategy

Determine the order of resources allocation according to sequence of task starting time and task list order sequentially. This algorithm is based on OPS with some modifies. The realization process of the strategy is simple, algorithm ideas are easy to understand and execution speed is relatively fast(comparable with OPS), which makes it suitable for the problems of resource "oversupply" and with less task conflict.

(3) MPS Strategy

Applying the OPS strategy in multi-step repeatedly would generate a variety of initial scheduling scheme. Before each application of OPS, a list of tasks and the time window should based on expert system rule set in order to modify the sequence of tasks and the time window in scheduling data. Establish the evaluation index system, evaluate each scheduling scheme generated by OPS, choose the optimal one. Compared with OPS, the execution speed is a little slower, whereas the scheduling scheme generated is much better, which makes MPS suitable for problems of medium resource conflicts.

(4) RAN Strategy

Firstly, randomly generate an initial scheduling scheme of problems to be solved based on unbiased manner, allow the infeasibility of the initial scheme, then modify it to be feasible. The greatest feature of RAN strategy is the "unbiasedness", which makes such strategy suitable to solve those scheduling problem under situation of FOM hard to understand. Thus RAN strategy can provide some unpredictable scheduling scheme through the basic scheduling rules.

(5) Determined Mixed Strategy

Since performance of the scheduling rules is affected by various parameters, none heuristic algorithm based on single rule can exhibit good scheduling performance in all satellite scheduling problems. Based on simple scheduling rules, we construct determined mixed strategy MR. Strategy selection process is as follows:

$$MR(OPS,SEQ,MPS,RAN)=\begin{cases}OPS, 0\le x\le p_1\\ SEQ, p_1<x\le p_2\\ MPS, p_2<x\le p_3\\ RAN, p_3<x\le 1\end{cases} \tag{12}$$

where, x is a random number within the interval [0,1], and p_1, p_2 and p_3 are constants within the interval [0,1].

Repeat the process to obtain multiple scheduling schemes. Then evaluate each scheme based on TOPSIS, and give out the optimal scheduling scheme.

3.2 Stochastic Strategy

Based on deterministic strategies, design stochastic strategy according to the idea of roulette method. Roulette method randomly selects better individuals according to the fitness. The probability of the individual to be selected depends on its fitness.

$$p_i=\frac{f_i}{\sum_{i=1}^{n} f_i}, \sum_{i=1}^{n} p_i=1 \text{且} p_i\ge 0 \tag{13}$$

where, p_i is the probability of individual i to be selected, f_i is the fitness of individual i, n is the number of individual in group. Therefore, the larger f_i is, the larger p_i is, and the probability of this individual to be selected is higher.

In the NOPS, we take task priority as the task fitness; in the NSEQ, take the order of tasks start time as the task fitness; in NMPS, take the sort tasks from the expert system rule set as the task fitness; and in NRAN, take the initial unbiased task scheduling order as the task fitness. Calculate the probability range each task been selected according to the fitness, set a random number generator to drive the wheel rotation, which would generate a set of initial scheduling scheme. Evaluate

advantages and disadvantages of all initial schemes comprehensively through the method of TOPSIS, and choose the optimal scheduling scheme in them.

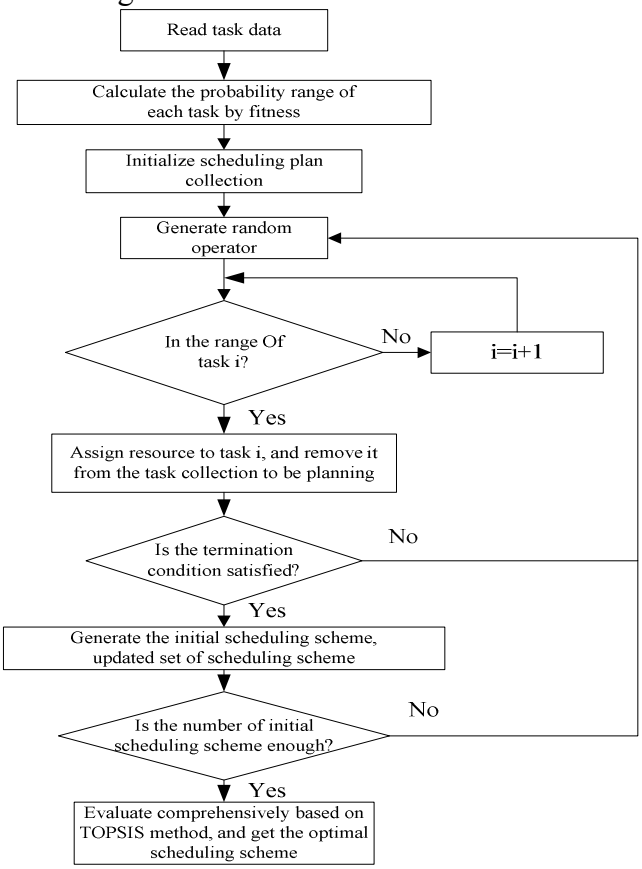

Fig. 1 Basic Flow of Stochastic Strategy

3.3 Stochastic Mixed Heuristic Algorithm

Taking these various stochastic strategy, based on the idea of hierarchical optimization, design Stochastic Mixed Heuristic Algorithm NMR, Algorithm is described as follows:

STEP 1. Determine the probability selecting range of each stochastic strategy, according to the specific circumstances of scheduling problems.

STEP 2. Initialization set of scheduling schemes.

STEP 3. Set the random number generator to drive wheel rotation, generate a random number to determine the type of stochastic strategy

STEP 4. Execute the strategy, obtain an initial scheduling scheme

STEP 5. Update the set of scheduling schemes, determine whether the number of scheduling schemes meet the demand, if meet, turn to STEP 6, otherwise back to STEP 3.

STEP 6. Evaluate each initial scheme based on TOPSIS, and give out the optimal scheduling scheme.

4 Experiments

To test and verify the effect of these methods for electronic satellite scheduling problem, we design several randomly generated examples of different size to conduct simulation experiments. There are 4 test examples with different task number of 50,100,150 and 200 respectively.

Assuming scheduling cycle is 24 hours, the priority of each task is a random number within the interval [1,10], and the duration of each task is a random number within the interval 100s~300s.

The results of example are shown in Fig.2~5. Among them, Fig.2~4 respectively show profit index, timeliness index and effectiveness index of 10 different algorithms to calculate each example. It can be seen that the five stochastic algorithms is generally optimum compared with its corresponding deterministic algorithm, however the advantage is not that obvious. Evaluation index

of NMR, MR, NRAN and RAN is superior to the others, while the rest six OPS, SEQ, MPS, NOPS, NSEQ and NMPS are of little difference generally. In fact, with the increasing scale of the problem, superiority of the former four is more obvious. Fig.5 shows the order indication value of different algorithm calculating each example. As can be seen, NMR is superior to the others, with MR, NRAN, RAN followed, and the rest are of little difference. Thus, by introducing the idea of random selection to consolidate variety of heuristic rules in scheduling, we can integrate the advantages of various algorithms, expand the space of feasible solutions, which enhance the algorithms' ability of searching optimization greatly.

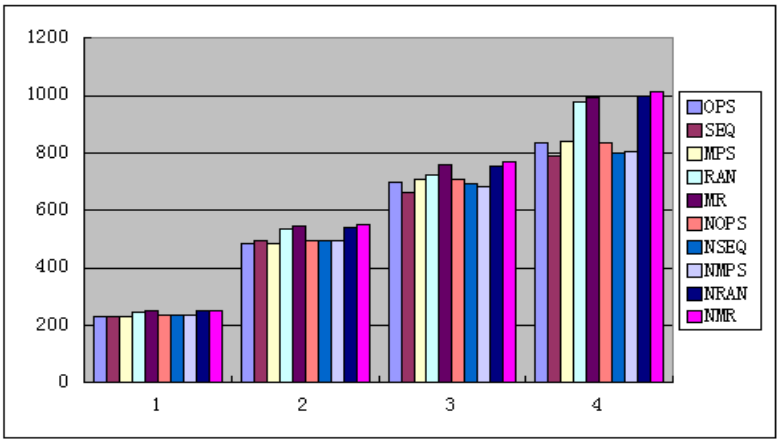

Fig. 2 Comparison Result of Profit Index

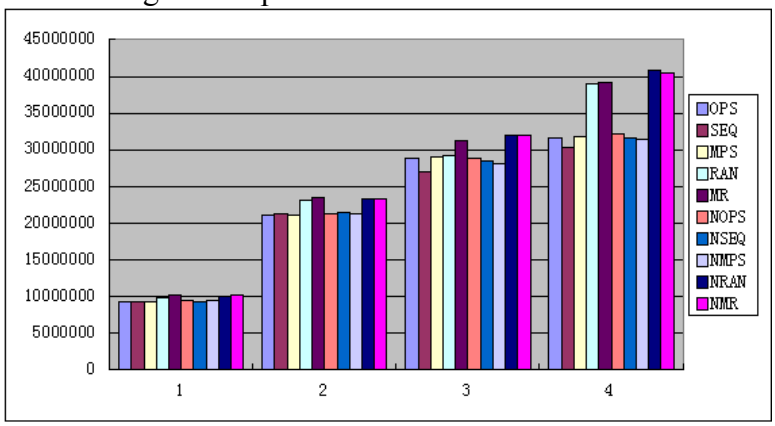

Fig. 3 Comparison Result of Timeliness Index

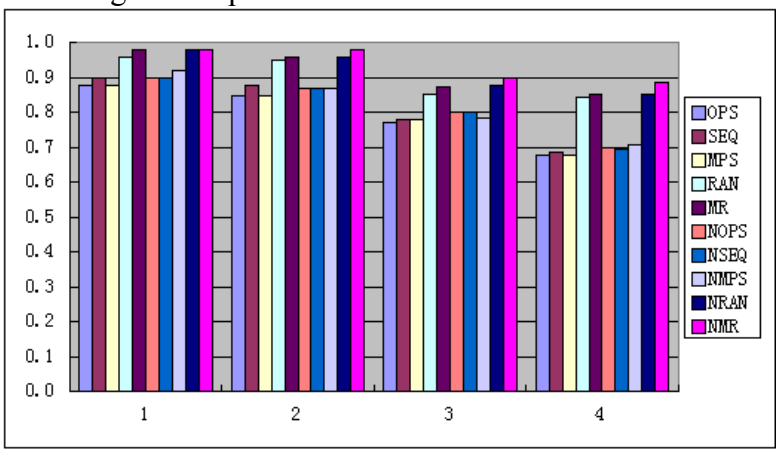

Fig. 4 Comparison Result of Effectiveness Index

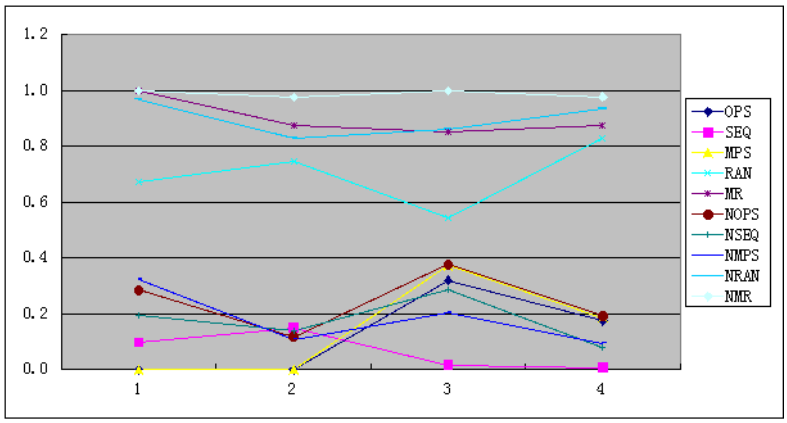

Fig. 5 Comparison Result of Indicated Value Sorted by TOPSIS

5 Conclusion

According to the relevant characteristics of electronic satellite scheduling problem, extract the main constraint, build a multi-objective programming mathematical model for electronic satellite scheduling problem. Propose several basic scheduling strategies, According to the hierarchical optimization ideas and thoughts of roulette, design rule-based heuristics, and comprehensively evaluate the solutions based on TOPSIS. Through comparative analysis of multiple test cases under different problem scale, it is shown that the introduction of the idea of random selection to consolidate variety of heuristic rules in scheduling can get on better scheduling result, which has some practical significance to solve practical problems.

Recent improvements in Image Retrieval

Zeng Yansheng, XulinYing

ComputerScienceandTechnology, TianjinUniversity,Tianjin300072,China;

yhzys@sina.com

Keywords: image retrieval, TBIR, CBIR, annotation, automatic.

Abstract. The target of this paper is to introduce the improvement of the technique of image retrieval. At first, it comes up with the concept of image retrieval and shows the importance of this technique. As the techniques of multimedia and Internet are developing rapidly, the resources of images that users obtain are also extended. And then this paper gives the problem about the image retrieval, namely the information of images are disordering. As the result, it is significant to do the effective organization, management and retrieval based on the increasingly extensive image information storage. After that, this paper presents the concept of TBIR and CBIR and gives the definitions of them. It proposes an issue that CBIR is the improvement of TBIR. Based on CBIR, there are also some disadvantages that need to be improved. In terms of the main point of CBIR, the paper raises that the annotation is one of the most difficult techniques that need to be promoted. Then it describes some algorithms about the technique of automatic image annotation. After these algorithms, the paper shows the challenges and developing direction of the technique of image retrieval. At last, it presented the conclusion to emphasize the main points of this paper.

Introduction

The research of image retrieval has been started since 20th century. As the techniques of multimedia and Internet are developing rapidly, and the standard of people's life is promoted, various resources on the Internet are becoming abundant, especially the information of multimedia because its characteristic of visualized. For this reason, the resources of images that users obtain are also extended.

The target that the technique of image retrieval should accomplish is to make users find the image they need more exactly and quickly [1]. In terms of the theory of image retrieval technique, there are three aspects. The first one is to create a query to retrieve the index of database, based on the analysis of the users' demands. Second one is to collect and cure the image resource, extract the characteristics, analyze and create the index of database based on this picture. At last, the most popular algorithm is to use the vector space. This algorithm is according to the similarity algorithm，computing the similarities of users' query and the records of index database, extracting the records which is fit for the threshold value, and printing out these records as descending order.

There are two periods that the development of image retrieval technique passes by, namely the text-based image retrieval (TBIR) and the content-based image retrieval (CBIR) [2]. In the past, people only master TBIR while these days, as the technology developing, CBIR comes out and more people tend to choose this technique.

1.0 The development of image retrieval technique

Since the 20th century, as the promotion from the research realms in database systems and computer visual, the technique of image retrieval has become a more dynamic research field. In the past, the main technique of image retrieval is TBIR, using the text to describe the characteristics of an image and doing the retrieval. For example, the current search engine, such as Google and Being are all based on the text. Instead of the content of images, the results depend on the file names of images or the text descriptions of images. Because the method of retrieval is single and the description of images are not comprehensive, these image search engine will not be too precise. This means the user should select from such many results that the efficiency of retrieval are not high. As the result, CBIR is created as the improved technique. This technique is to analyze the

color, shape, texture and some other characteristics of the image, in order to make the retrieval more effective and precise.

1.1 Text-based image retrieval technique

The technique of image retrieval is begun with the research of TBIR. TBIR is to store images into a database, when retrieving a picture, users can access the file name or keywords as the image index, setting up relationship between the storage path of image and the keywords. It is general that the method to do the retrieval is to scan the classified catalogue or do the keyword query. In essence, these kinds of retrieval accomplish the accurate matching or the probability matching to the description of image [3].

As the quantity of images is rapidly increasing, the problem of TBIR has been coming out. First is the workload of marking all the images manually is quite large. Currently, the technique of computer visual and artificial intelligence cannot mark images automatically. This means the work of marking images will cost a lot of time. Second, because of the differences of personal subjective cognition, different people will have different comprehensions according to one image. However, the method of retrieval will use the keywords created from the marker to accomplish, which may generate some error matching, and will influence the reliability of the retrieval. At last, the visual features of images are various, such as shape, color, texture and some others, these will not be described by text objectively.

There are some typical applications that are based on the technique of TBIR, such as Yahoo! Picture-Gallery. Yahoo! Picture-Gallery has stored more than 40 thousand pictures. These pictures have been categorized and indexed according to art, technology, entertainment, animal, science, sport and some others. Users should scan, or input the keywords to do the image retrieval.

1.2 Text-based image retrieval technique

CBIR is based on feature of images, color, shape, texture and semantics respectively, is committed to query the image. It is aimed at querying the image that is similar to the typical example from the comprehension of image. This retrieval technology is different from the traditional one, which they use distinct method to accomplish retrieval task. The technology reflects quantized features that store the content of media and media. It uses the Query By Example based on similar measurement to come true the retrieval function. Compared to the traditional one, it adds some new technologies, such as technology of image comprehension, technology of pattern recognition, to offer the more powerful method of retrieval to the users.

In terms of CBIR, there are also some successful examples such as QBIC. QBIC is an image retrieval system developed by IBM company. It is the first CBIR system for business, and is one of the most popular image retrieval systems. This system is based on the image retrieval services of the web, using color, shape, texture and some other features as the characteristics of the query. The query is presented by drawing or any other imaging approaches [4].

2.0 The current situation of TBIR and CBIR

2.1 The comparison of TBIR and CBIR

Both TBIR and CBIR exist the advantages and disadvantages. It is supposed that CBIR is the improvement of TBIR.

In some extent, TBIR is more simple and flexible to operate and it is also accustomed for users to access it do the retrieval. In current circumstances, the majority of search engines have equipped with this function because this technology comes true simply. However, it also has a weakness, namely the limitation retrieval range of text. It is even easy to confuse about the description of words and languages. In addition, the annotation used to mark the image is different, which will decrease the rate of precision ratio and comprehensive of searching image.

[2] refers that CBIR improves the disadvantage of TBIR. First of all, as a kind of retrieval technique, it must provide the information or material of image recourses to users in a reasonable period from a large distributed database. Transparent is a characteristic in CBIR. Hence, the user need not understand the object of image and attempt to describe the format of text. User just needs to care about the way they prefer to query the information. It offers a quick way to find the object.

Secondly, CBIR adds the feature library and optimization algorithm. Feature library is going to store the visual feature, such as shape, color, texture and some others. The optimization algorithm is committed to increase the efficiency of query and the speed of matching. It is used the objective description of image of visual feature to increase the rate of query efficiency and accuracy.

2.2 The limitation of CBIR

The CBIR opens a more distinct and accurate approach to quickly query a large amount of image information online. However, it still has many imperfections, which can be:

1. **Low precision ratio.**
   Currently, most of all image retrieval engines cannot achieve the extent most of users are satisfied. As it queries the image, the user needs to query the object from thousands of images. Users cannot endure to spend long time on retrieving information. What's more, the worst thing is that sometimes the search engine cannot provide the information users want.
2. **The information of the image features extracted is not accurate.**
   In these years, the popular using in retrieval technique based on the content of image is mostly based on low-level visual feature. In fact, this is broken away from actual semantic of the image. If it just depend on low-level features to classify what the image includes, it is impossible. The low-level features do not have the ability to recognize the object. For example, usually the user wants to post an image as a query to do the retrieval, the system cannot find the one what the user wants to look for [5].
3. **The connection of user query is not ideal.**
   In the ideal image retrieval system, people can be active and the connection of user query can provide abundant interactive abilities. Furthermore, it also is a distinct and simple way to query image. However, the current technologies represent that the connection of user query in retrieval engine is still singleness and less interactive ability. In some case, the retrieval engine just offer the annotation of connection of query, dialog box of keywords.

3.0 The improvement of image annotation

The key techniques to realize CBIR are extracting the features of images and matching. There are two classifications according to the extraction of features, namely the low level features and the high level semantic contents. The low level features are some basic features of the image, such as color, shape and texture. The high level semantic contents are some high level of conception of the image, which need people to recognize and explain, and these will rely on the knowledge that people acquired. As the development of CBIR is limited, the CBIR cannot support the high level semantic contents. Currently, the mutual retrieval algorithms are most based on the low level features, namely using color, shape, texture and some other features to do the retrieval. After extracting, the data should do the operations such as index and dimensionality reduction.

As the importance of extracting features of the image, the technique of image annotation has become more and more significant.

1. **Automatic image annotation**

Automatic image annotation is to generate the text annotation automatically by the computer system according to the content of image visual. Generally, the annotation can be the category of the image, or some keywords. Thus, people can use a more mutual technique to do the index and retrieval for the image. For the cause that the quantity of images is increasing rapidly, the technique of manual image annotation has been more expensive [6]. As the result, the technique of automatic image annotation is becoming increasingly important.

2. **Different algorithms to realized the automatic image annotation**

In the automatic image annotation, the information to be marked is always the text words or some limited information of category. A simple way to accomplish is to train a corresponding binary classifier according to every word. When the system comes across a new image, it can use these classifiers to judge if this word should be an annotation of this image, and then it can create the image annotation.

In terms of the classification of information, one of the algorithms is to use the support vector machine (SVM) to categorize the area of the image [6]. Firstly, it uses several algorithms to do the image segmentation, in order to segment the image into different areas and recognize the salient regions of them [7]. And then the system will do the manual annotation to mark the category information to these salient regions, and regard them as training data. Each area should be departed into some tiles that can overlap with each other and every tile is include 4*4 pixels. The distribution information of the HSV color space and the relative gradient information are used as the features annotation of this tile. When training each binary classifier of a word, the system will use several tiles that are from the positive area and the negative area to do the training to SVM model. At last, collecting all the annotation information from different areas, and putting them together, after that, it will obtain the annotation of this image.

Another algorithm is to regard this issue as a point of translation between two languages: one is made by text words and the other is made by the vision words in order to describe the image. For the reason that the language translation model need to present these two languages as discrete symbols, the system regards the limited categories that are clustered by the image areas as the vision words. This algorithm firstly access normalized cut to segment the image into different areas that are not overlapping. And then use the K-Means method to do the cluster, and each of the result will be called as a kind of blob, namely the relative vision words category. And then this algorithm accesses a machine language translating method to build up the relationship between area categories and the text words. This method is called translation model (TM) [8]. To improve this algorithm, it is better to do the clustering for the text words. After that, it uses the TM into the translations between these conceptions and blob, and making the results more effective.

4.0 The challenges and developing direction of the technique

The most important keys of CBIR are two: one is to find the features of images that are suit for human being's vision while the other is to promote the speed of responses during the retrieval. In term of these two technologies, people should consider the following three aspects:

1. **Relevance.**
   The vision features of human beings are relative to the low-level image features, and more and more researchers have accepted the method of image retrieval turns to the direction of semantic. Relevance is a significant way to connect these two features.
2. **The performance evaluation criterion and the set of test**
   A positive evaluation criterion may lead the technique to a right direction while a negative one will mislead the research work. In terms of current situation, the performance evaluation criterion is the precision and recall. Moreover, to make a balanced, large-scale test database is also an important issue.
3. **The combination among the cross realms.**
   To accomplish a more effective technique of image retrieval，it seems need the efforts from cross realms.

Conclusion

In conclusion, as the unstructured resources have become increasingly abundant and the Internet have become more popular, it seems that users tend to access websites to retrieve the pictures what they want. This paper is based on the improvement of the technique of image retrieval, coming up with some kinds of techniques to make the image retrieval more effective. According to the analysis, image annotation is one of the most significant techniques. It is proved that automatic image annotation will bring more efficiency than the manual image annotation. Although the technique of image retrieval has been somewhat mature, there is still a large space to progress. Nowadays, the technique cannot accomplish to extracting the high level semantic content, to deal with these kinds of problems, people need to do more research.

Although this paper is relative comprehensively describing the improvement of technique of image retrieval, it seems need further research to make the research completed and comprehensive.

Keywords: Firefly Optimization (FA), Image segmentation, Otsu, Mineral belt image

Abstract. Otsu is one of better image segmentation algorithm, which obtains optimum threshold by maximizing the between-class variance of an image. However, computation time will sharply increase as the threshold increase. In order to greatly improve the problem, a new segmentation algorithm called firefly algorithm based on Otsu's method is presented in this paper, and applied the algorithm to segmentation of mineral belt image of shaking table, which lay the foundation for automation of shaking table. Experimental results show that the new algorithm can accurately segment different mineral belts and can obtain the same optimal thresholds and fitness values with Otsu's method.

Introduction

Image segmentation is an important step during the course of image processing, and thresholding is a simple and effective method, and the key technology is getting optimum threshold. At present, thresholding is widely used in some spheres [1], such as medical image segmentation, infrared thermal image segmentation, synthetic aperture radar image segmentation, moving object segmentation.

Otsu's method is one of commonly used thresholding algorithm, which can select an optimal threshold to maximize the between-class variance[2]. It can be easily extended to multi-level thresholding, but computation time will rapidly increase because it obtains optimum threshold by exhaust search[3]. To greatly improve the performance of the algorithm, Swarm intelligent optimization algorithm is combined with Otsu's method [4]. In 2008, Zhiwei Ye and others propose a new segmentation algorithm combining Otsu's method with particle swarm optimization algorithm to reduce computation [5].

Firefly algorithm is a new swarm intelligent optimization algorithm, which inspired by the social behavior of flashing of fireflies and presented by Xin-She Yang[6]. And it is compared to particle swarm optimization and genetic algorithm, the results of the experiment demonstrate that firefly algorithm is better than the two swarm intelligent optimization algorithm [7,8]. So we propose a new segmentation algorithm by combining firefly algorithm with Otsu's method in this paper, that is Otsu's method based on firefly algorithm.

At present, the position of mineral board and process variables is adjusted by artificial during the course of mineral dressing, which has wasted labor, the lower accuracy, real-time and separation indexes. In order to overcome the disadvantages, the new segmentation algorithm is used to segmentation of mineral belt image of shaking table in the paper.

This paper is describes the basic principles of Otsu's method in Section 2, introduces the firefly algorithm in Section 3, segmentation results of mineral belt image and analysis in section 4, followed by the conclusion in the section 5.

Otsu's method

Otsu's method was proposed by Japanese scholar Nobuyuki Otsu and is named after his namesake. Assume an image has N pixels and L gray levels, the number of pixels at level i is represented by f_i, then $N = f_1 + f_2 + \cdots + f_l$. The occurrence probability of level i is defined by

$$p_i = \frac{f_i}{N}, p_i \geq 0, \sum_{i=1}^{L} p_i = 1 \tag{1}$$

Assume the image contains two classes of pixels, the optimum threshold t divides the image into two classes, A and B, the cumulative probabilities and mean levels can be calculated respectively:

$$\omega_A = \sum_{i=1}^{t} p_i, \quad \omega_B = \sum_{i=t+1}^{L} p_i \tag{2}$$

$$\mu_A = \sum_{i=1}^{t} ip_i / \omega_A, \quad \mu_B = \sum_{i=t+1}^{L} ip_i / \omega_B \tag{3}$$

where ω_A is the cumulative probabilities of class A that contains of gray levels from 0 to t, ω_B is cumulative probabilities of class B.

Then the image of between-class variance is given by

$$\sigma^2 = \omega_A(\mu_A - \mu_T)^2 + \omega_B(\mu_B - \mu_T)^2 \tag{4}$$

where μ_T is the mean levels of whole image, $\mu_T = p_A\mu_A + p_B\mu_B = \sum_{i=1}^{L} ip_i$.

In Otsu's method the optimum threshold t^* is searched exhaustively by maximizing the between-class variance, then the optimal threshold is

$$t^* = \arg\max_{1 \leq t \leq L} \{\sigma^2(t) \left| \sigma^2 = \omega_A(\mu_A - \mu_T)^2 + \omega_B(\mu_B - \mu_T)^2 \right.\} \tag{5}$$

Firefly algorithm (FA)

In the firefly algorithm, fireflies are randomly placed in the search space by the following mathematical equation, which contain a light intensity:

$$x_i = rand \times (upper \quad range - lower \quad range) + lower \quad range \tag{6}$$

where x_i is the position of firefly i, upper range and lower range are respectively the upper range and lower range of search space.

Firefly algorithm has two important factors: the variation of light intensity and formulation of the attractiveness. Light intensity is associated with the position and objective function of firefly. The intensity of firefly can be presented by the following equation:

$$I = I_0 \times e^{-\gamma r_{ij}} \tag{7}$$

where, I_0 is the original light intensity , γ is the light absorption coefficient that is an constant parameter, and r_{ij} is the distance between firefly i and firefly j.

The attractiveness of firefly decides the direction of movement and the equation is as follows:

$$\beta = \beta_0 \times e^{-\gamma r_{ij}^2} \tag{8}$$

where, β_0 is the attractiveness at $r = 0$. The movement equation of firefly i to j is as follows:

$$x_i = x_i + \beta \times (x_j - x_i) + \alpha \times (rand - 1/2) \tag{9}$$

where, x_i and x_j is respectively position of firefly i and j, and firefly j is more brighter than firefly i. In the term, α is a randomization parameter, $rand$ is random number generator uniformly distributed in $[0,1]$.

During the course of movement, the fireflies with the lower light intensity move toward the brighter fireflies. After many movements, the majority fireflies gather the optimum value of the given objective function space.

Firefly algorithm based on Otsu's method

This section we apply firefly algorithm based on Otsu's method to segment mineral belt image of shaking table. The original images are shown in Fig.1, which are tin images from the concentrator. The experiments are carried out on a 2.70GHz CPU personal computer with 2G RAM under windows XP system. To ensure the validity, every experiment is done 20 times independent.

Table 1 The optimal thresholds and fitness values

Test images	Optimal thresholds		Optimal fitness values	
	Otsu	New algorithm	Otsu	New algorithm
image(a)	94,182	94,182	5464.4	5464.4
image(b)	95,183	95,183	5492.8	5492.8
image(c)	91,131,171	91,131,171	1255.9	1255.9

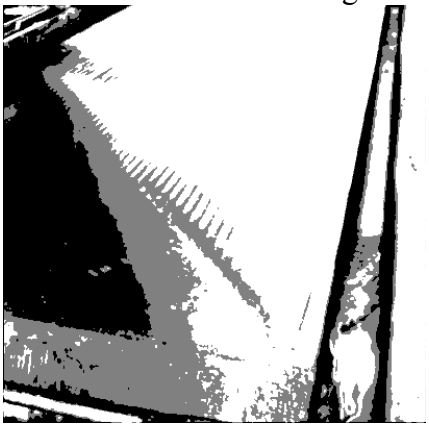
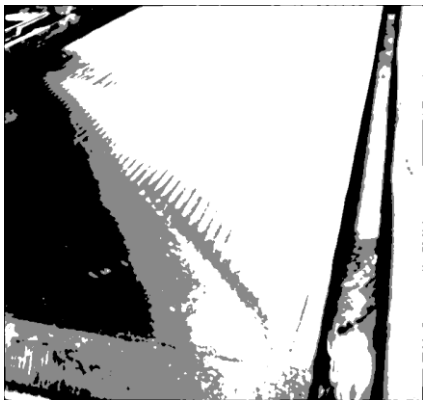
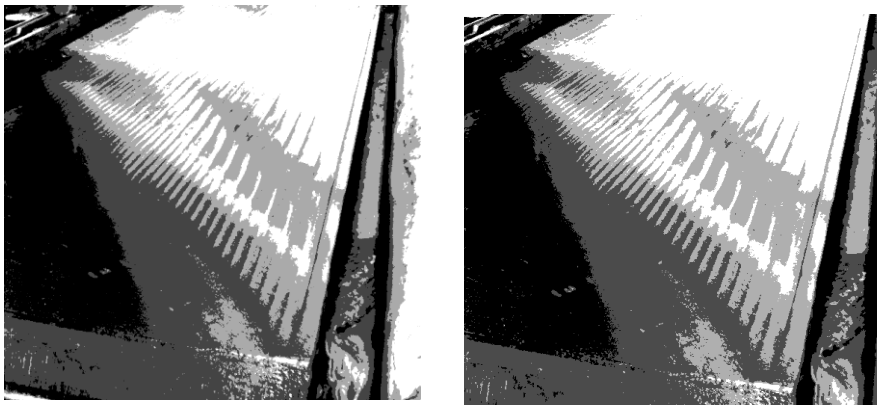
Fig. 1 Orginal image



(a)



(b)



(c) (d)

Fig. 2 Segmented image used new algorithm

To test the performance of firefly algorithm based on Otsu's method, we execute the algorithm on the four images and compare the performance of the algorithm with Otsu's method. The optimal thresholds and fitness values are shown in Table 1. Obviously, the new algorithm can obtain the same optimal thresholds and fitness values with Otsu's method, and the new algorithm can divide the mineral belts into concentrate, middling and tailings for image (a) and image (b). And image (c) and image (d) are segmented into concentrate, time concentrate, middling and tailings.

Conclusions

To overcome the shortcomings of Otsu's method, we combine firefly algorithm with Otsu's method and present a new segmentation algorithm. Experimental results show that the new algorithm has good segmentation performance, which can segment different mineral belts and can obtain the same optimal thresholds and fitness values with Otsu's method, so it is suit for mineral belts image.

Keywords: IEEE 802.11 MAC, IEEE 802.15.4 MAC, Hidden Terminal, RTS/CTS.

Abstract: The IEEE 802.11 and IEEE 802.15.4 are two of the most popular wireless network protocols. And it is very important to look into the differences between IEEE 802.11 MAC and IEEE 802.15.4 MAC. The main goal of this paper is to look into the hidden terminal problem of the MAC layers of 802.11 and 802.15.4 based on NS2 platform. Through a dedicated experiment, the author compares the results based on the NAM animation and throughput and then explains the reasons respectively.

1. Introduction

The IEEE 802.15.4 [1] and IEEE 802.11 [2] are two of the most popular wireless network protocols. It is expected that low rate wireless personal area networks (LR-WPAN) will be used in a wide variety of embedded applications, in which numerous embedded devices running on batteries are distributed in an area communicating via wireless radios. While wireless local area networks (WLAN) aim to provide high throughput, low-latency for traditional file transfer and multimedia applications.

The MAC protocol plays a significant role in determining the efficiency of wireless channel bandwidth sharing and energy cost of communication. There have been some studies about the performance of IEEE 802.15.4 MAC and 802.11 MAC respectively. Gang Lu et al [3] evaluated the MAC performance of IEEE 802.15.4 in the simple star-topology. Hongqiang Zhai et al [4] analyzed a few performance metrics of the wireless LAN and give explanation to the performance degradation in delay and throughput at various traffic loads. There have been some studies about coexistence between IEEE 802.15.4 and IEEE 802.11 also. Sofie Pollin et al [5] studied the impact of a heavily loaded IEEE 802.15.4 network on an IEEE 802.11 network. But none of them look into the hidden terminal problem of IEEE 802.15.4 MAC and IEEE 802.11 MAC.

In this paper, a dedicated experiment of the same scenario with RTS/CTS mechanism enabled and disabled that uses IEEE 802.11 MAC protocol is used to compare the performance differences between RTS/CTS enabled wireless networks and RTS/CTS disabled wireless networks. The throughput is used as performance measure. Which is defined as the average value of the number of bytes of the current sampling time and the number of bytes of the previous sampling time, and the unit of throughput is Kb/s.

This paper is organized as follows. Section 2 brief overviews the IEEE 802.15.4 MAC and IEEE 802.11 MAC. In Section 3, the experiment is introduced and the results of NAM animation are given. The main performance measure throughput is used to analyze the differences between the two MAC protocols in Section 4. Finally, this paper concludes in Section 5.

2. Overview of the MAC protocol in IEEE 802.11 and IEEE 802.15.4

2.1 Overview of the MAC Protocol in IEEE 802.11

The 802.11 standard specifies a single Medium Access Control (MAC) layer and several physical layers. The MAC layer implements functions that enable the sharing of the common air medium [8].

The distributed coordination function (DCF) implements a carrier-sense protocol and supports only asynchronous communications. The DCF is suitable for sending information such as data files and bar codes, but it is not very efficient for sending broadband, time-critical information.

The 802.11 standard provides for an optional point coordination function (PCF) medium access mechanism, which is implemented in the access points and (in addition to the mandatory DCF) that provides delivery of time-bounded data via synchronous communications using station-polling mechanisms. This mechanism is capable of transporting video effectively as compared to the DCF.

2.2 Overview of the MAC Protocol in IEEE 802.15.4

In this section, we briefly review the MAC protocol specified in the IEEE 802.15.4 standard. More details of the protocol can be found in [6].

The MAC layer of IEEE 802.15.4 has two operating modes: beacon-enabled mode and non-beacon-enabled mode. In the beacon-enabled mode, a personal area network (PAN) coordinator transmits a beacon periodically to form the superframe time structure, as shown in Fig. 1. A superframe consists of a beacon that enables the beacon-enabled mode, contention access period (CAP), contention free period (CFP), and an optional inactive portion. The CAP and CFP together form the active portion of the superframe, during which all communication among the nodes should take place. In the CFP, the network coordinator controls entirely the contention free channel access by assigning guaranteed time slots (GTS) to those nodes with their GTS requests granted. Depending on the specific scheduling scheme used, the performance analysis of CFP is actually the same as that of the well-studied centralized scheduling schemes in cellular systems. And in the CAP, a slotted CSMA/CA is defined in the standard [7].

In the non-beacon mode, nodes use the carrier sense multiple access with collision avoidance (CSMA-CA) mechanism to contend for channel access. If the channel is idle, the transmission of a frame will begin immediately, otherwise the node will backoff and try to access the channel later.

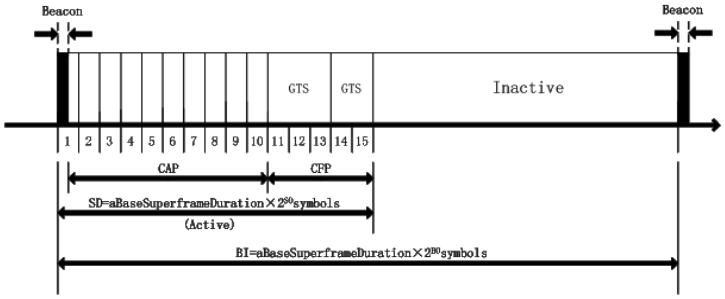

Fig. 1. IEEE 802.15.4 superframe structure in the beacon-enable mode

3. The Experiment: The Hidden Terminal Problem

The so-called hidden terminal problem, refers to a node, which is within the scope of coverage of the receiving node, but is outside the scope of the coverage of the sending node. Therefore, the node could not intercept the data sending of the sending node, and at the same time, transmit data to the same receiving node. At this time, it will make the data compete at the receiving node. After the competition has been generated, the node will retransmission the data that is not successful transmitted due to competition, thus lowering the coefficient of utilization.

Both IEEE 802.15.4 and IEEE 802.11 use the CSMA/CA mechanism, but their CSMA/CA mechanism has some difference. The main difference is that in IEEE 802.15.4, there is no RTS/CTS handshake mechanism, while in IEEE 802.11, it is possible to use the RTS/CTS handshake mechanism. So the hidden terminal problem could only be solved in IEEE 802.11.

This scenario includes three nodes, two nodes numbered 1, 2 act as the source nodes of data flow, while node 0 act as the destination node of date flow. Node 1 and node 0, node 2 and node 0 are two groups respectively. Each group of source node and its corresponding destination node are connected via UDP and bind with CBR application. Set reasonable topology, so that node 1 and node 2 are within the communication range of node 0. While node 1 and node 2 are out of the communication range of each other. The simulation time is 20 seconds. The topology of the three nodes is shown in Fig. 2.

Fig. 2. Topology of the three nodes

At 1.0, node 1 begins to send data to node 0. And at 2.0, node 2 begins to send data to node 0. At 15.0 stop sending data. Finally, end the simulation at the time of 20.0.

4. The Analysis of Throughput

Throughout is an important parameter to analyze wireless network. The experiment shows different results when the RTS/CTS mechanism is enabled and not enabled. It uses Phy/WirelessPhy as the network interface type and Mac/802_11 as the MAC layer type.

After running the Tcl file, two files are generated. Then they could be used to draw the throughput graph by using gnuplot. Fig. 3 shows the throughput graph that enables the RTS/CTS mechanism, while Fig. 4 shows the throughput graph that disables the RTS/CTS mechanism.

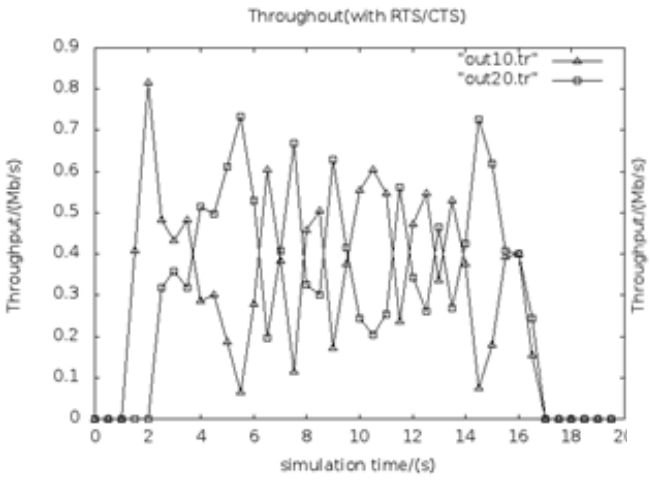

Fig. 3. Throughput(RTS/CTS enabled)

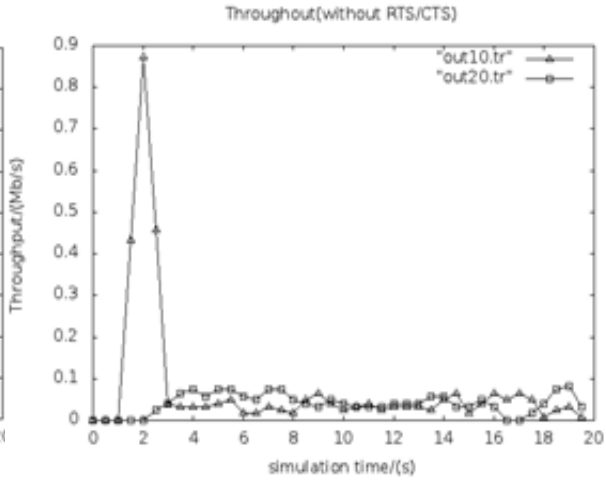

Fig. 4. Throughput(RTS/CTS disabled)

As shown in the figures above, when the second wireless transmission link begins data transmission at 2.0, both of the circumstance generate competition phenomena, but their results have

huge difference. In Fig. 3, that is, when the RTS/CTS handshake mechanism is enabled, through this mechanism, could avoid the hidden terminal problem. Through handshake signal, the two wireless transmission links could use the channel in turn. From the figure, we could see that when the throughput of one wireless transmission link fluctuate to its peak, the other wireless transmission link fluctuate to its trough. But in Fig. 4, that is, when the RTS/CTS handshake mechanism is disabled, the two wireless transmission links compete with each other, which reduce the transmission efficiency greatly.

From the experiment, it can be concluded that it is very effective to solve the hidden terminal problem by using the RTS/CTS mechanism. But it adds RTS frame and CTS frame. Therefore, this way will also increase the extra burden. As the length of them are 20 bytes and 14 bytes respectively. For IEEE 802.11, because the data transfer rate is higher, the length of the two kinds of control frame is not very great in comparison with the length of the data frame, and could avoid the greater waste of resend the data frame because of the conflict. But for IEEE 802.15.4, the data transfer rate is much lower than that of IEEE 802.11, the length of the two kinds of control frame is comparable to the length of the data frame, even greater than the waste of resend the data frame because of the conflict. So it is not very wise to use the RTS/CTS mechanism in this situation.

5. Conclusions

From the hidden terminal problem experiment, we observed the Different situations when enable and disable the RTS/CTS mechanism in IEEE 802.11 MAC. The hidden terminal problem could be solved in IEEE 802.11 by using RTS/CTS mechanism. And because the length of the two kinds of control frame is comparable to the length of the data frame in IEEE 802.15.4 MAC. RTS/CTS mechanism is not used in IEEE 802.15.4.

Keywords: Halftone; Error diffusion; Ordered dithering; Bidirectional feedback; Correction factor

Abstract. Halftone is the key technique for low-resolution equipment like fax machines and printers to reconstruct grayscale images with black and white binary data. Images produced by classic error diffusion algorithm have more abundant color than those made by ordered dithering method. But the problems still exits that there can distortions and false contour phenomenon and fuzzy edges. This paper puts forward an advanced error diffusion algorithm based on bidirectional feedback and improves its feedback type through adding correction factors. The simulation results show that the bidirectional feedback error diffusion algorithm with correction factors better inhibited the phenomenon of distortions and false contour. Directional texture is also improved greatly.

Digital halftone image technique is a technology that transforms an original image with continuous tone into discrete binary pattern of black and white so as to make it have subjective visual effects of continuous tone. It is widely used in printers, fax machines and other binary printing and display equipment.

Over the past twenty years, the digital halftone technique has made great developments by the advent of some good technique, such as ordered dithering[1], the error diffusion algorithm[2], DSB algorithm[2], point diffusion algorithm[3], etc. Among these algorithms, the error diffusion algorithm is widely used and studied because of its good image quality, rich color, anisotropy and no regularity of pixel distribution and its low computational complexity. But the halftone image processed by error diffusion method has the problems of moire and net dot phenomenon together with fuzzy edges and severely missed details. So T.D.Kite and others proposed the improved error diffusion algorithm by referring threshold parameters for threshold modulation of the original error diffusion algorithm. In this paper, with correction factor based on bidirectional feedback error diffusion method further inhibiting distortions and false contour phenomenon and improving directional texture, halftone images are made closer to the original images.

The principle and analysis of error diffusion algorithm

The basic idea of error diffusion algorithm is firstly to compare the current pixel of the grayscale image with a threshold to get a binary output, and then diffuse the pixel differences of input and output to the untreated area with a certain distribution coefficient. This method is an iterative method and there are very big differences compared with other non-iterative halftone methods. In error diffusion algorithm, the quantization error of each pixel of is not only related to the input and output pixel of the position, but is also affected by the quantization error of the treated area. Error diffusion algorithm is therefore a halftone algorithm based on region, and is no longer a point processing procedure[2].Compared with ordered dithering algorithm proposed by Bayer, the halftone images processed by error diffusion method have richer color and their pixel distributions are anisotropic and irregular. But there are still two problems, one is the phenomenon of distortions and false contour appearing in various zones of the halftone image, which means obvious artificial texture will appear in higher and lower brightness zones, as is called the "worm effect"[4]; another

one is that there is a severe loss of detail in the image and the color is inconsistent near fuzzy edges. Due to dot overlapping effect on output devices, it will make the phenomenon more obvious, making the overall image darker.

The improved error diffusion method based on the bidirectional feedback

In error diffusion process, the quality of halftone image varies due to different error filter coefficient. On the idea of error diffusion method of classical single feedback, two error filters are presented in this paper to change one-way feedback into bidirectional feedback. And the correction factor of the error diffusion filter is added to improve. Owing to the error distribution coefficient of each pixel is no longer a fixed value, the added filter and correction factor can adjust the error distribution coefficient in time, which makes diffusion coefficient of error diffusion in an area more reasonable.

In this paper, the filters added in bidirectional feedback error diffusion method introduce the middle frequency band between high frequency and low frequency, which makes the halftone image has a good transition on the band, so as to get a higher quality images.

Figure No.1 is the principle diagram of the improved error diffusion method.

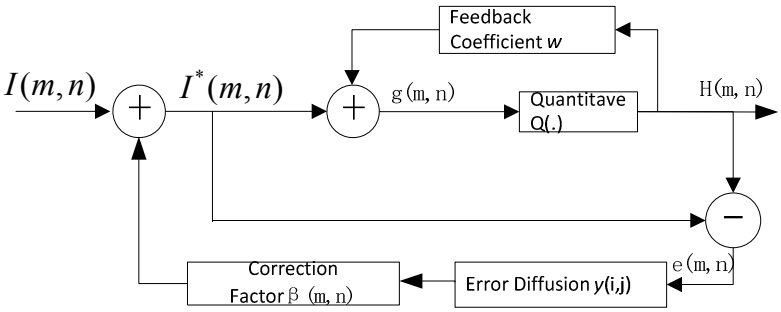

Fig.1 Principle diagram of the improved error diffusion method

Set I , I^* , H respectively represent the input of gray image, the input image after the diffusion of last step, the output of binary image. (m,n) means coordinates of pixel. The flow chart of error diffusion method can be expressed as:

$$I^*(m,n) = I(m,n) - \sum_{m,n} \beta(m.n) * y(i,j) * e(m-i, n-j) \quad (1)$$

()

$$H(m,n) = Q[g(m,n)] = Q[I^*(m,n) + \sum_{k,l} w(k,l) * e(m-k, n-l)] \quad (2)$$

$$e(m,n) = H(m,n) - I^*(m,n) \quad (3)$$

Apply filter y and filter w, in which filter y adopts the principle of diffusion in table 1 and the weight distribution coefficient. * * represents the pixel location of current dot; the arithmetic ratio in other positions represents the error diffusion weight of relative position with current pixel.

Table1 Error diffusion filter y

		**	5	7
3	7	5	7	3
3	3	7	3	3

In the classic error diffusion method, Floyd and Jarris-Judice-Ninke both used error diffusion filter with a fixed weight distribution, but in fact the human eye's sensitivity to noise of different detail areas in image and detail itself is different[5], then the fixed weight distribution cannot be processed very well in the detail part of the image. Here apply a correction factor $\beta(m,n)$ based on regional distribution of variance of a specific image to adjust the weight distribution of filter in time; therefore we make weight distribution better adapted to changes in the luminance values for each pixel.

Steps to determine the correction factor are as follows:

(1) Divide the area with the filter module width of 3×5, calculate the variance of each pixel region as variance of the area. The formula is:

$$p(m,n)=1/13\sum_{i,j}(I(m-i,n-j)-H(m-i,n-j))^2 \tag{4}$$

In which $p(m,n)$ means the regional variance of (m,n).

(2) Select the threshold point of region variance. We choose five characteristic value, as K_i（i=1,2,3,4,5）,from the regional variance as the threshold point of it, then on the basis of regional variance image can be divided into five detail areas. If $K_i < p(m,n) < K_{i+1}$, which means pixels at (m,n) belong to the area i, then we can decide the details area of each pixel by regional variance values;

(3) Calculate the correction factor $\beta(m,n)$ according to the following formula:

$$\beta(m,n)=\frac{p(m,n)-K_{i-1}}{K_i-K_{i-1}}\delta_i+(\delta_{i-1}-\delta_{i-2}) \tag{5}$$

In which δ_i means the experience parameter of correction factor. The choice of δ_i can be used to improve the quality of the halftone image according to the human visual characteristics and the experience of processing image.

Error diffusion filter w can help to introduce middle frequency band. It applies the diffusion principle and distribution weight in table 2:

Table 2 Error diffusion filter w

	**	7
3	5	8

In the table, * * represents the pixel location of current dot; the arithmetic ratio in other positions represents the error diffusion weight of relative position with current pixel.

The analysis of simulation and performance

Simulation based on Matlab platform, this paper uses lena.bmp and PEPPERS.bmp with 256 grayscales as the original image. Respectively we use the classic error diffusion method, error diffusion method based on the bidirectional feedback and error diffusion method with correction factors for image processing.

The classic error diffusion method chooses Floyd filter. The experience parameters δ_i used in correction factors are shown in table 3:

Table 3 Experience parameters

Area ID i	1	2	3	4	5
Experience parameters δ_i	0.05	0.7	0.5	-0.2	0.06

Figure 2 are a comparison for halftone image resulted from three kinds of algorithms and the original image.

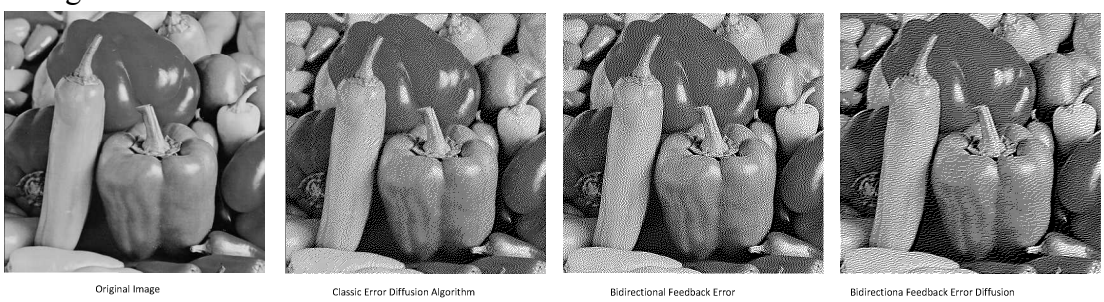

Fig. 2 Comparison of PEPPERS.bmp Quality between 3 Algorithms

The Image quality assessment is to measure the quality of representation by the error it deviates from the original image. Methods are divided into subjective assessment and objective assessment. From subjective view, images resulted from bidirectional feedback error diffusion method are superior to the ones from conventional error diffusion method. There is no clear directional principle. Tone appears more continuous after adding correction factor. We get better approximation to the original image and clearer edges thus retaining more details of the original image information.

In the simulation we use two indicators MSE(mean square error) and PSNR (peak signal-to-noise ratio), to evaluate image quality. The evaluation result is shown in table 4.

Table 4: Evaluation result

algorithm name		Classic algorithm （Floyd filter）	Bidirectional feedback error diffusion method	Bidirectional feedback error diffusion method with correction factor
Image of lena	MSE	17.5476	16.1370	15.4682
	PSNR	35.6886	36.3748	36.7693
Image of PEPPERS	MSE	18.2462	17.5274	15.4359
	PSNR	35.5191	35.6936	36.2455

By the evaluation results, the image effect received from bidirectional feedback error diffusion method is obviously better than that of the conventional error diffusion method, and the correction factor are introduced to further reduce the mean square error, which shows that the method of adding middle frequency band between low frequency and high frequency through double feedback and then using correction factor to adjust the weight of error diffusion based on region variance can effectively reduce the difference between the halftone image and the original image, which makes the halftone image closer to the original image.

Summary

The classic error diffusion method of Halftone algorithms are analyzed in this paper, and on this basis, by adding filter we introduce the middle frequency band and error correction factor to adjust weight distribution, thus we improve the phenomenon of "distortions ", "outline" and directional texture. The direction of next research is to use multiple sets of experience parameters δ_i in simulation test, and to find a set of correction factor of experience parameters δ_i which are more appropriate. Then we can make the processed image avoid the appearance of artificial texture in a larger degree.

Research and Implement of Digital Image Watermark Based on DCT

Liyan Liu

Shandong University of Political Science and Law, Ji Nan, Shandong Province, 250014,China

email: Liuliyansd@163.com

Keywords: Digital Watermarking; Discrete Cosine Transforms (DCT); Robust

Abstract. With the rapid development of communication technology and Internet technology, as well as the popularization of computer, the application of digital multimedia technology is more and more widely, video, voice and image gathering, editing, storage, and dissemination of digital information has become more and more convenient. However, it is because of the computer and the network popularization and the fragility of the digital information itself, digital multimedia data are more vulnerable to attack, digital products is also very easy to forged and tampered with. According to these digital multimedia data more easily by illegal processing problem, people put forward the concept of digital watermark. Digital watermark technology is used to realize the protection of digital information. In this paper, the digital watermark technology research starting from the practical application, the digital image watermark based on DCT domain is studied.

Introduction

Digital media has been widely used on people's life, study, work and entertainment, and plays an increasingly important role. However, a number of important digital information may have been stealing, malicious attack and tampered with; Some digital products is easy to get the goods without owner's permission to reproduce and spread by people with the content of the copyright, and achieve the purpose of illegal. As a result, the enthusiasm of digital products producers is diminished, which hinder the development of information industry. To solve above problems, the original method is implemented by encrypting access control and security, but this method cannot completely solve the problem, on the one hand, the encrypted file due to the not understanding of itself in the transmission process will be blocked; On the other hand the encrypted file is easy to attract the attention of the attacker to attack, or cracked and file if the encrypted file is cracked and its protection also disappear, the file content can be arbitrarily unauthorized copying and transmission. Therefore, in the open network environment, the digital watermarking technology situational became a new kind of international copyright protection of digital products and data security maintenance technology effectively. For now, the digital watermark technology is a kind of effective measures and powerful means to realize the media information security, copyright protection and security products, widely used in anti-counterfeiting source, copyright protection, digital certification and safety communications and other fields.

Digital Watermark Technology

The basic principle of digital watermark

Digital watermark technology will directly embed the iconic information into the digital carrier (including software, video, documents, sound, image, etc.), such as: Logo, product serial number, Logo, etc of the individual, and usually does not affect the use value of the original digital carrier, also won't easily to detect and modify again. By hiding in the watermarking information in the digital carrier, can realize products anti-counterfeiting, copyright protection, data integrity, authentication, digital fingerprinting, radio listening, copy control, secure communication, etc.

The concept of DCT

Algorithm is the core of the digital watermark technology, with the continuous development of digital watermark technology, the kinds of watermark algorithm is also emerge in endlessly. Spatial

watermark algorithm, transform domain watermark algorithm and compressed domain watermark algorithm is one of the typical algorithms.

Nowadays, research mainly focused on the transform domain digital watermark algorithm. Based on the transform domain watermark algorithm embedded watermark information will not be easily detected. Because after transformation, the energy of the image become scattered, not easily perceived a single frequency. The typical algorithms of transform domain are discrete cosine transform (DCT Discrete Cosine Transform).

The basic idea of DCT decompose no embed watermark image into 8×8 small pieces, then respectively transform each small piece of DCT, then quantify the results of after transformation in turn, coding in the end. Each small piece of original image after DCT transformation, correction coefficient according to the watermark on the DCT, in order to ensure the correct watermark embedding, and then on each small piece of DCT inverse transformation, when all the sub-block is completed after the process after got the embedded watermark image.

Design and Implement of Image Digital Watermark algorithm based on DCT

The generation of watermark

Before making a watermark embedding, we choose suitable digital image for the laboratory as a watermark image, watermark image should be K×K binary image. This thesis, we select the school pin of Shandong University of Political Science and Law as a watermark image for this experiment. First of all, according to the requirements of this test, the image is set to 64 x 64 sizes and saved as a BMP format images. Secondly, using MATLAB tool to read images, the image grayscale and converted into a binary image. The original image and the converted binary image is shown by fig. 1 (a) and fig. 1(b).

Fig. 1 (a) Gray scale image

Fig. 1 (b) Binary image

Watermark embedding

1) The selection of location

Watermark embedding position should be able to make the watermark information to satisfy their invisibility and robust, and has strong ability against the attack. Due to the strength of the watermark too affected the image visual quality, the strength is too small will make the watermark information is easily damaged. Therefore, the strength of the watermark wants moderate is neither too big nor too small. Because the energy of image signal mainly concentrated in the low frequency part of the DCT domain, the signal energy of the low frequency part is more, so the watermark information should be embedded in the human feel the most important component in the low frequency region, so the watermark system has better resistance to attack. And when the image distortion happens, still can keep the main part of the image.

To sum up, the intermediate frequency part of DCT domain is regarded as the watermark embedded in the best location, can simultaneously satisfy the invisibility and robust of digital watermark

2) The embedding process

According to the selection of watermark embedding positions, we choose the watermark embedded into the intermediate frequency area of DCT domain. Choose a 512 x 512 image as a carrier of BMP format. The watermark embedding process is shown by fig. 2.

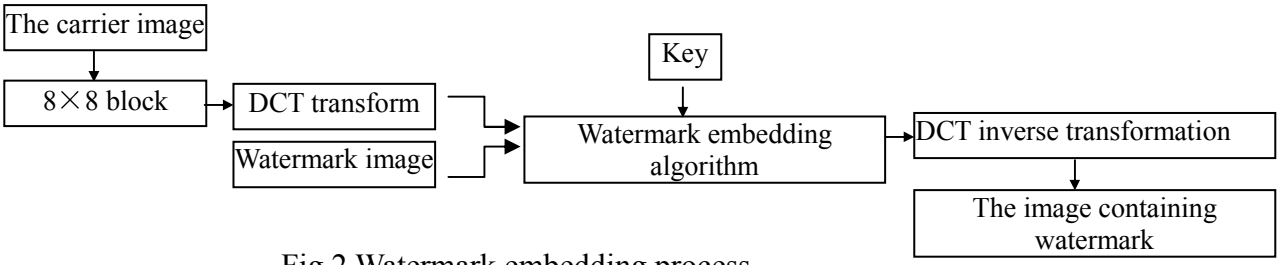

Fig.2 Watermark embedding process

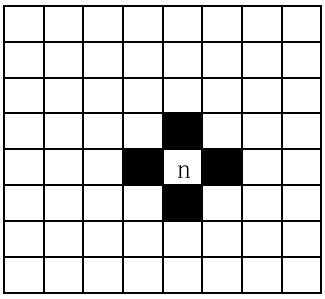

Fig. 3 The location of the n

Watermark embedding key code is as follows:

```
key = 32;
n = 5;

for p = 1:N
    for q = 1:N
        % computing block location information
        x = (p-1)*K+1;
        y = (q-1)*K+1;
        % Extract the piece
        BLOCK = I(x:x+K-1, y:y+K-1);
        % DCT transforms D
        BLOCK = dct2(BLOCK);
temp = mean(BLOCK(n,n-1)+BLOCK(n,n+1)+BLOCK(n-1,n)+BLOCK(n+1,n));
        if J(p, q) == 0
            % If the black pixels
        BLOCK (n,n) = temp + key;
        else

The analysis of experimental results

The robust verification

The robustness is one of the most important characteristics of digital watermark technology. The robustness of the watermark is refers to the original image containing watermark, after through some process, the watermark information is still able to maintain the integrity, and can be accurately identified. In the above experiments, the key value is different; its effect is also different. We choose

the key take 64 and 4 and the experimental results are analyzed. As shown by fig. 4 and fig. 5. Comparing the experimental results when the key take 4, 32, and 64, the quality of the image is lower, the value of key is smaller, the robustness of the watermark is lower.

The watermark image extracted

The image containing watermark

Noise attack

In order to verify the watermark's ability to resist noise attack, to embed the watermark image respectively after joined the salt and pepper noise and gaussian noise, and the watermark image of after add noise watermark extraction. Among them, the salt and pepper noise intensity a is 0.005 and 0.01, the mean of gaussian noise is 0, variance b takes 0.001 and 0.005. Watermark image after add noises shown by fig. 6, the extracted watermark image is shown by fig. 7.

Filtering attack

In order to verify the Ability of watermark to resist filtering attack, we do to embed watermark image respectively linear filtering, median filtering and adaptive filtering processing, and the treated watermark image watermark extraction. The watermark image after filtering processing is shown by fig. 8, the extracted watermark image after filtering processing is shown by fig.9.

Conclusion

In the experiments, the main research problem is the watermark embedding location selection and the selection of embedding strength and watermark embedding algorithm selection. Found by experiment, the algorithm on the premise of meet the invisibility of watermark has a certain resistance to attack ability. Such as gaussian noise attack on watermarking image, the watermark can still under gaussian noise of a certain intensity attacks from primitive watermark extracted with high similarity watermark information, at the same time, the algorithm also has certain robustness

for filtering attack. But, at the same time we also see some disadvantages of the algorithm, such as watermark information has weak robustness under the image processing of increasing strength, we finally won't be able to extract the watermark information from the watermark image, lead to the watermark information was damaged. When used in actual system so need to further improve the performance of the algorithm is further perfect the watermarking scheme, thus improve their practical value.

Keywords: Gabor Wavelet Transform; Improved Local Tangent; Face Recognition

Abstract. In this paper, Gabor filtering and linear local tangent space alignment algorithm and its improved algorithm are used on face recognition. The Gabor wavelet transform can detect the image information in different directions and scales, according to its selective direction and frequency characteristics. The LLTSA reduces the dimension of the sample while the LLTSA and the other improved algorithms extract secondary feature. Experiment and analyze the average recognition rate of the LLTSA and its improved algorithms with the variation of dimension. The experiment results show the effectiveness of the method, increasing the face recognition accuracy.

Introduction

Face recognition usually refers to capture images via smart devices, process image, extract effective identification information and finally identify the classification. Usually face recognition system is mainly divided into four stages. In the first stage we need to face detection, the second stage is to position the separated face feature point. The need for the third phase is to extract the feature from the extracted image. The final stage is a pattern classification of individual. [1]

This paper researches Gabor filtering and linear local tangent space alignment algorithm and its improved algorithm for face recognition. Since the linear local tangent space alignment algorithm may not be optimal projection direction and the field selection needs to be optimized, the linear local tangent space alignment algorithm has been improved in the paper. The experiment proved that the effects of the improved algorithm applied to the face may be raised.

Gabor Filter

Gabor wavelet [2] is proposed through the improvements of the Fourier transform. Fourier transform for the first time introduced the concept of frequency, making it a good solution to convert problems into the frequency domain which can be difficult in the time domain.

The definition of the two-dimensional Gabor wavelet transform and its core function are as follows:

$$\Psi(x,y,\omega,\theta)=\frac{1}{2\pi\sigma^2}\exp\left(\frac{-\left(x_0^2+y_0^2\right)}{2\sigma^2}\right)\left(\exp(j\omega x_0)-\exp\left(\frac{-\omega^2\sigma^2}{2}\right)\right) \tag{1}$$

Among the above formula, $x_0 = x\cos\theta + y\sin\theta, y_0 = -x\sin\theta + y\cos\theta$, x and y represent the spatial domain of the image, ω represents the center frequency, σ represents the standard deviation of Gaussian kernel function.. Moreover, $\exp\left(\frac{-\omega^2\sigma^2}{2}\right)$ represents the DC component. Since the existence of the DC component, the image will not be affected by the absolute values of the gray image and also be not very sensitive to light. $\exp\left(\frac{-\left(x_0^2+y_0^2\right)}{2\sigma^2}\right)$ is Gaussian kernel function and is limited by a Gaussian window function to observe its local information.

According to equation (1) we can know that Gabor filter [3] does well in the identification ability in the spatial domain and frequency domain. In the spatial domain, it changes the image direction by adjustment. Besides in the frequency domain, we can adjust it to have a good selectivity. Choosing different values of ω and θ extracts information on the different directions and scales. Figure 1-1 and Figure 1-2 shows the filtered schematic of the two-dimensional filter bank on the ORL .

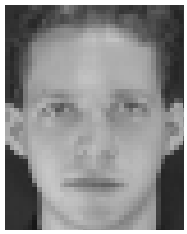

Fig.1. The original image in the ORL face database

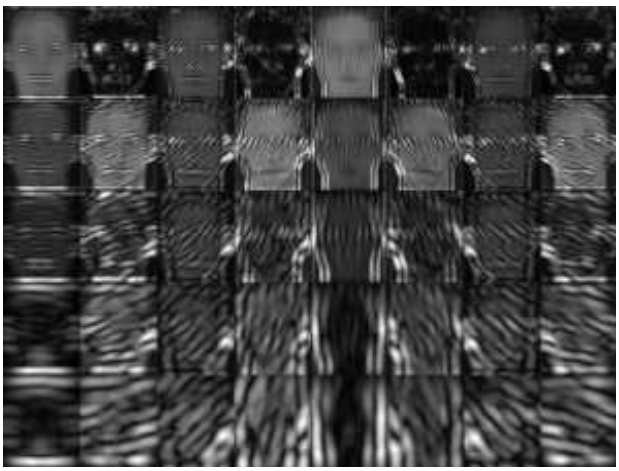

Fig.2. The real part after two-dimensional Gabor filters filter the original image

Linear Local Tangent Space Alignment Algorithm (LLTSA)

Linear local tangent space alignment algorithm (LLTSA) [5] is a linear optimization algorithm for LTSA. The algorithm projects the samples in that direction to reduce the dimension by finding the optimal projection direction. The following describes the algorithm:

Suppose there is a set of samples consisting of $\{x_1, x_2, \ldots, x_n\}$, X_i represents the sample matrix $X_i = [x_{i1}, x_{i2}, \ldots, x_{ik}]$ of k-nearest neighbor for sample points x_i. The aim is to try to find a projection matrix A so that the sample set projects according to the projection direction to obtain the sample points after the projection. The sample points matrix after the projection is configured as $Y = [y_1, y_2, \ldots, y_n]$, and the matrix meets the linear mapping $Y = A^T X H_N$, $H_N = I - e_n e_n^T / n$, e_n represents the column vector of all ones, the purpose of adding H_N is to make the mean be zero between each sample.

The Improvements of Linear Local Tangent Space Alignment Algorithm (LLTSA)

For popular learning, LLTSA will face the problem of adaptive selection. Literature [6] gives the standard for judging whether a neighborhood set of linear subspace determined by best-fit will approach the popular tangent space with high accuracy. According to the literature, the approximation standard of the tangent space is:

$$\left\| X_i - \left(x_i l_{k_i}^T + \tilde{Q}_i \Theta_i \right) \right\| \le \eta \left\| \Theta_i \right\|_F \tag{2}$$

In the formula, $X_i = \lfloor x_{i1}, x_{i2}, \ldots, x_{ik_i} \rfloor$; the right singular vectors of the largest d singular values of $Q_i = \left[x_{i1} - \tilde{x}_{i,}\ x_{i2} - \tilde{x}_i, \ldots, x_{ik_i} - \tilde{x}_i \right]$ consist of a matrix, $\Theta_i = \left[\theta_1^{(i)}, \theta_2^{(i)}, \ldots, \theta_{k_i}^{(i)} \right]$, $\theta_j^{(i)} = Q_i^T \left(x_{ij} - \tilde{x}_i \right)$; $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_{k_i}$ is the singular values in descending order of the matrix $X_i - \tilde{x}_i l_{k_i}^T . Q_i$ is the corresponding right singular vectors of the maximum d singular value. The original standard is equivalent to:

$$\sqrt{\sum_{j \geq d} (\lambda_j)^2} \leq \eta \sqrt{\sum_{j<d} (\lambda_j)^2} \tag{3}$$

According to the above criteria, it will be very easy to get the neighborhood selection criteria, making LLTSA algorithm be the adaptive neighborhood selection, so it is called the improved algorithm the adaptive linear local tangent space alignment algorithm (ALLTSA).

LLTSA algorithm is an unsupervised algorithm linear. As we know that the category information of training samples, we take its classification information into account to improve LLTSA algorithm. We call the improved algorithm discriminated linear local tangent space alignment algorithm (DLLTSA).

In order to eliminate the redundant information, one way is to take constraint of basis vectors on the orthogonal form so that the improved algorithm is called for the orthogonal linear permutation algorithm local tangent space (OLLTSA). The other way is to look for the best vector identification set with statistical uncorrelation, eliminating existed the redundant information of the base vectors, thus we call the improved algorithm unrelated linear local tangent space alignment algorithm (ULLTSA).

Face Recognition Algorithm Based on Gabor Filter and LLTSA

In this paper, integrating Gabor features and algorithms based on the linear local tangent space alignment algorithm for face recognition [7] and experimental comparison. Specific algorithm steps are as follows:

Suppose $X = \{x_1, x_2, ..., x_n\}$ as n pieces (c classes in all) of training images, x_i is the image matrix.

(1) Filtering each face images with Gabor filter in different frequencies and directions to get a lot of groups of Gabor features, n and m respectively represent number and frequency.

(2) Sampling for Gabor features of each group in groups and blocks to get lower dimension characteristics getting the composition of an image matrix c_i, the combination of methods is mentioned above.

(3)For the n samples set $C = \{c_1, c_2, ..., c_n\}$, use $(2D)^2 PCA$ to reduce dimension, then each image matrix is connected by line end to end, each image constitutes a column vector x_i, the matrix $X = [x_1, x_2, ..., x_n]$ is composed of n pieces of pictures.

(4) A secondary feature extraction is to use linear local tangent space algorithms for feature extraction.

(5)Classify the test samples using the above four steps to obtain a low-dimensional feature vector images and then use the classifier for classification.

Comparison and Analysis of the Experimental Results

In this paper, the experiment uses a self-built library of 120 individuals, 20 photos per person, including all kinds of information gestures, facial expressions and so on. For each person, we randomly sample 10 images as training samples, take the remaining 10 as test samples, cycle 20 times and take the average rate as the correct recognition rate. When adding adaption to the algorithm we use the letter A, when the discrimination we use the letter D, when orthogonal we use the letter O, adding no correlation with the letter U.

The results are the variation of dimension followed by the average recognition rate of the five algorithms (LLTSA, OLLTSA, DLLTSA, ALLTSA, ULLTSA) based on face database (abscissa represents the dimension, the vertical axis represents the average recognition rate of the algorithm, the following experiments are the same). The experimental results are shown in Figure 4-1:

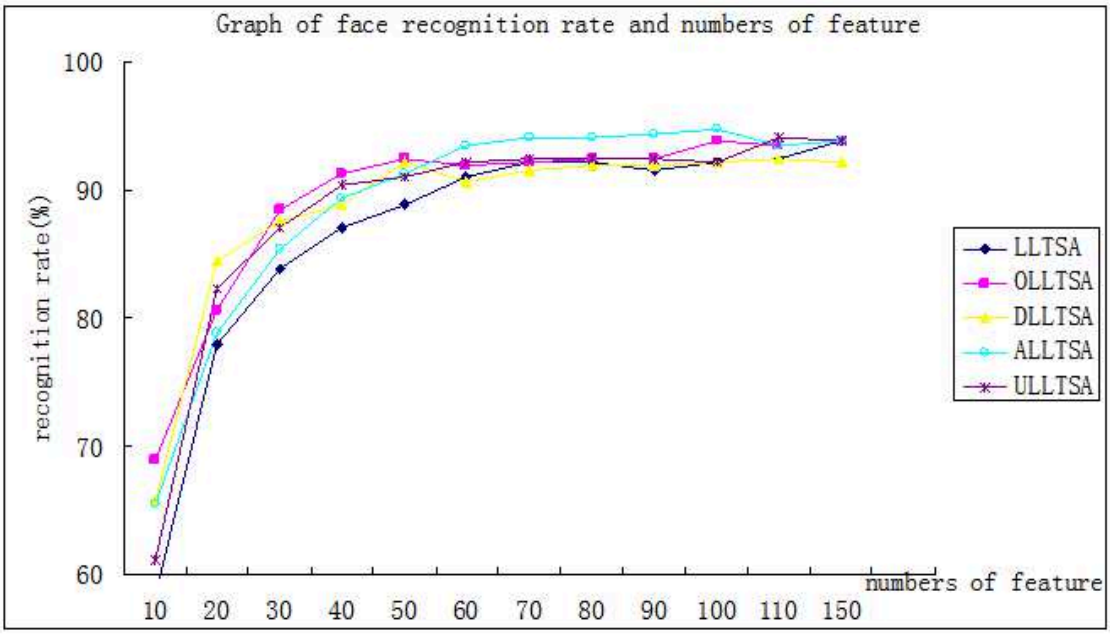

Fig.3.The variation of dimension followed by the average recognition rate of the five algorithms based on face database

From the figure above, between 10-60 dimension the algorithm OLLTSA, DLLTSA, ALLTSA, ULLTSA have improved the recognition rate compared to the linear local tangent space algorithm. After 60 dimensions their recognition rates approach a straight line basically reaching to the maximum recognition rate.

Conclusion

The model adopted and modified with the adaptive algorithm can play a great role in improvement. When adding class information, applying the priori knowledge will help improve the algorithm and recognition rate. After this, constraining the base vectors helps looking for the best vectors to improve algorithm, finding the optimal projection direction to improve the recognition rate, therefore, these improvements can well improve the performance and robustness of the algorithm.

Keywords: Low density parity check (LDPC) codes; additive white Gaussian noise(AWGN); multiple access channel(MAC); degree profile; density evolution; differential evolution

Abstract. A new way to optimize the degree profiles for irregular LDPC codes in MAC is presented. The combination technology of differential evolution and density evolution is applied in the optimizing of degree distributions. By using a greedy algorithm we show the differential evolution method to seek the maximum noise threshold in MAC channels under different degree number and maximum degree condition.

Introduction

Multiple Access Channel (MAC) is extensively used in modern communication systems. The classical MAC models a communication system in which independent transmitters send messages to a receiver, and Liao[1] derived the capacity region of the classical MAC. Haghi[2] investigates the capacity problem for some multiple-access scenarios with cooperative transmitters and proves a coding theorem.

The indispensable way to approach the capacity region of MAC is by means of coding. Low-density parity-check (LDPC) codes have been shown to achieve low bit-error rates (BERs) at signal-to-noise ratios (SNR) very close to the Shannon limits on many binary-input channels [3][4]. Therefore, LDPC codes are considered to be among the most power-efficient binary codes for digital transmission. If the degree profiles of LDPC codes are optimized, they can be used in MAC. Therefore, it is of great significance to make an attempt to design good LDPC code ensembles for MAC.

In this paper a method used to optimize the LDPC ensemble in MAC is proposed. And based on the method, both good LDPC code ensembles and threshold are obtained under different conditions.

Density Evolution Based on Gaussian Approximation

The design of good degree profiles which give asymptotically good performance in AWGN has been addressed in[5][6]. By approximating the messages passed between Variable Nodes (VN) and Check Nodes(CN), VN and Channel Function Node(CFN) as Gaussian, we have proposed a method to search the degree profile in MAC[7]. Now we will elaborate a way to find the degree profiles that maximize the standard deviation of noise.

Code restraint

The degree profile of LDPC codes is defined as

$$\lambda(x)=\sum_{i=2}^{dv_{\max}}\lambda_i x^{i-1},\ \rho(x)=\sum_{i=2}^{dc_{\max}}\rho_i x^{i-1} \tag{1}$$

Where dv_{max} and dc_{max} are the maximum degree of variable node and check node respectively. And $\lambda(1)=1 \quad \rho(1)=1$ is satisfied. The code rate R and the degree profiles satisfies the following constraint.

$$(1-R)\sum_i \frac{\lambda_i}{i}=\sum_i \frac{\rho_i}{i} \tag{2}$$

Therefore the dependency between them should be removed. By removing the dependency, we can get

$$\lambda_2 = 1 - \sum_{i=3}^{dv_{\max}} \lambda_i , \tag{3}$$

$$\rho_2 = 1 - \sum_{i=3}^{dc_{\max}} \rho_i \tag{4}$$

$$\lambda_{dv_{\max}} = \frac{\frac{R}{2} + \sum_{i=3}^{dc_{\max}} \rho_i \left(\frac{1}{i} - \frac{1}{2}\right) - (1-R) \sum_{i=3}^{dv_{\max}-1} \lambda_i \left(\frac{1}{i} - \frac{1}{2}\right)}{(1-R)\left(\frac{1}{dv_{\max}} - \frac{1}{2}\right)} \tag{5}$$

In this way we can ensure the independency of variable. Let D denotes the number of free elements of the degree sequence (λ,ρ), following the constraint(2),(3),(4), combined with the fact that $\lambda_1 = \rho_1 = 0$, it is easy to find that $L = dv\max + dc\max - 5$. We can form a D-dimensional parameter vector $p = (\lambda_3, \lambda_4, \ldots, \lambda_{dv\max-1}, \rho_3, \rho_4, \ldots, \rho_{dc\max})$ and our objective is to choose the elements of this vector so as to maximize the largest noise threshold.

For a variable node i with degree dv, it receives information from dv-1 neighboring check nodes and channel output, and sends extrinsic information to the target check node j.

Differential Evolution

This is a global optimization problem over continuous spaces, and differential evolution is quite suitable for it. Starting from an initial set of vectors, the algorithm iteratively updates each vector in the set until a vector is found which has the best cost function value. In the following, we briefly review it.

(1) Initialization

Starting from a certain noise level σ, which is the standard deviation of the noise, we randomly choose NP D-dimensional vectors $v_{i,G}$ (i=0,1,…,NP-1) for the first generation G=0, where NP = 20D is an integer that is a constant during the optimization process. Density evolution is run for each vector $v_{i,G}$ as in[7]and its residual error $Pv_{i,G}$,i.e. the fraction of incorrect messages is recorded. The vector with the smallest $Pv_{i,G}$ is labeled as the best vector, $v_{best,G}$.

(2) Mutation

For the next generation, i.e.G+1, new trial vectors are generated according to the following mutation scheme. For each i=0,1,…,NP-1, randomly choose distinct integers r_1,r_2 from [0, NP-1], each different from the index i, and define

$$v_{i,G+1} = v_{best,G} + F \cdot (v_{r1,G} - v_{r2,G}) \tag{6}$$

Where F is a real constant which controls the amplification of the differential variation, and F = 1.0 in our optimization. For each vector, the density evolution is run and its residual error, $Pv_{i,G+1}$, is recorded.

(3) Selection

For each i=0,1,…,NP-1, $v_{i,G+1}$ is obtained as follows:

$$v_{i,G+1} = \begin{cases} v_{i,G+1}, & if\ Pv_{i,G} > Pv_{i,G+1} \\ v_{i,G}, & if\ Pv_{i,G} \le Pv_{i,G+1} \end{cases} \tag{7}$$

Denote the vector with the smallest residual error by $v_{best,G+1}$..

(4) Stop condition

If the residual error $Pv_{best,G+1}$ of the vector $v_{best,G+1}$ is not zero (practically, it is not less than a very small value), return to step 2. Otherwise, increase the noise level by a small value, and return to step 2. If the noise level is increased to a value for which the residual error of the best vector does not converge to zero, the process is stopped. The vector whose residual error goes to zero at the highest possible noise level is labeled as the best vector v_{best}, and the corresponding noise level as the threshold σ*.

In the differential evolution process, a greedy algorithm is applied to search the maximum threshold for a given degree. The trial degree profile is generated in every generation for every population. And the optimum degree profile is obtained. The flow chart to seek the maximum threshold is illustrated in Fig.1. By this way, the degree profile and corresponding threshold are both obtained.

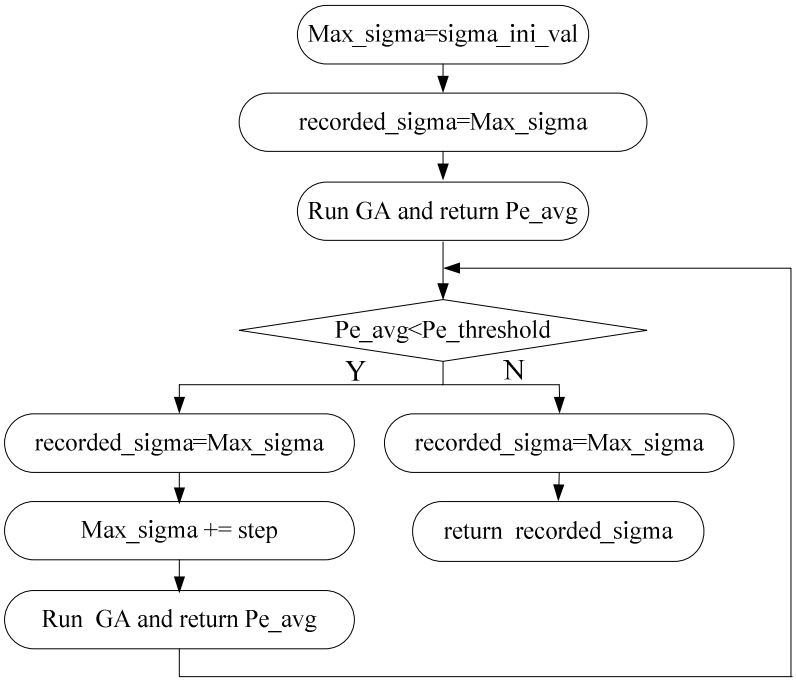

Fig.1 Flow chart to obtain the maximum sigma.

Results

In the differential evolution process, the parameter is set according to Tab.1.

Tab.1 The parameters used in differential evolution

dvmax	dcmax	gene_max	code_rate	Iteration_no	Sigma_ini_val	user_no
20/30/40	10	10	0.5	1000	0.0001	2

The dvmax and dcmax denotes the maximum degree of variable node and check node respectively. The gene_max denotes the maximum generation number of differential evolution. The code_rate denotes the code rate of LDPC code. The iteration_no denotes number of iteration in density evolution process, sigma_start user_no denotes the number of users in MAC.. The optimized degree profiles are shown in Tab.2, Tab 3 and Tab 4 with dvmax being 20, 30, and 40 respectively. The dv_no represents the number of variable node degree, and D(σ) in the table stands for the variation of the optimized threshold. It can be seen from these tables that the noise threshold varies slightly with the number of variable node degrees, i.e. the more the degree number, the higher the noise threshold. By comparison of Tab.2, Tab.3 and Tab. 4 we can see that the higher the maximum degree, the higher the threshold, and the variation is quite small. Considering the complexity in construction of LDPC code, four or five degree is enough.

Summary

.Differential evolution is an optimized search technology and it is used in the search of good degree profiles of LDPC codes in AWGN MAC. In the search process, the target function is defined as the residual error and a greedy algorithm is proposed to seek the maximum noise threshold. Good degree distributions are obtained in MAC channels and these degree distributions are evaluated by density evolution algorithm to satisfy the error probability requirement.

Keywords: remote sensing image, FPGA, neural network, compression encoder

Abstract. The characteristics of remote sensing image are big data volume and high resolution. It is difficult to meet actual demands by using traditional techniques for transmission and storage. This paper studies and designs remote sensing image compression encoder with FPGA technology and three-layer feedforward BP neural network. The neural network can parallelly process large amounts of data, and has a structural characteristic of self-learning and self-organizing. The encoder has a simple structure, safety, fast speed, good reconfiguration. It overcomes shortcomings of conventional compression techniques which compress high-resolution images ineffectively. The study has some theoretical values in the field of image compression.

Introduction

With the development of high-tech science and technology, satellite remote sensing technology will grow rapidly. That is, remote sensing data will grow exponentially, the current channel capacity and transmission capacity are difficult to reach its transport requirements. So the compression of remote sensing data is an effective method to solve the problem. It can effectively improve confidentiality and transmission rate of remote sensing data .

There are many traditional image compression methods, such as JPEG, effective wavelet compression method, etc. These methods only apply to some low-resolution ordinary images, but high-resolution remote sensing images which must get higher requirements of data compression. Traditional compression encoders are difficult to meet actual demands, so they are processed by a more efficient compression encoder.

This paper proposes a three-layer feedforward BP neural network algorithm, which uses its own characteristics to achieve remote sensing data compression encoder. The characteristics have the highly parallel, the synchronization information storing and processing, and the self-organizing and self-learning. Besides, it implements compression encoder with reconfiguration and flexibility of FPGA technology. The encoder has some characteristics of high compression ratio, high security and speed in order to meet actual needs.So it has some prospects in the field of image compression.

All manuscripts must be in English, also the table and figure texts, otherwise we cannot publish your paper.

BP neural network compression principle and algorithm

Remote sensing image compression principle: Fig.1, a set of input pattern is mapped to another set of output pattern by a small number of hidden layer units, and the output mode is equal to the input mode. The input layer is original image, the output layer is reconstructed image, the hidden layer is compressed image. In fact, the data processing between input layer and hidden layer is coding process, and decoding process is between hidden layer and output layer. Compression ratio is the ratio of input layer nodes and hidden layer nodes (less than input layer nodes).

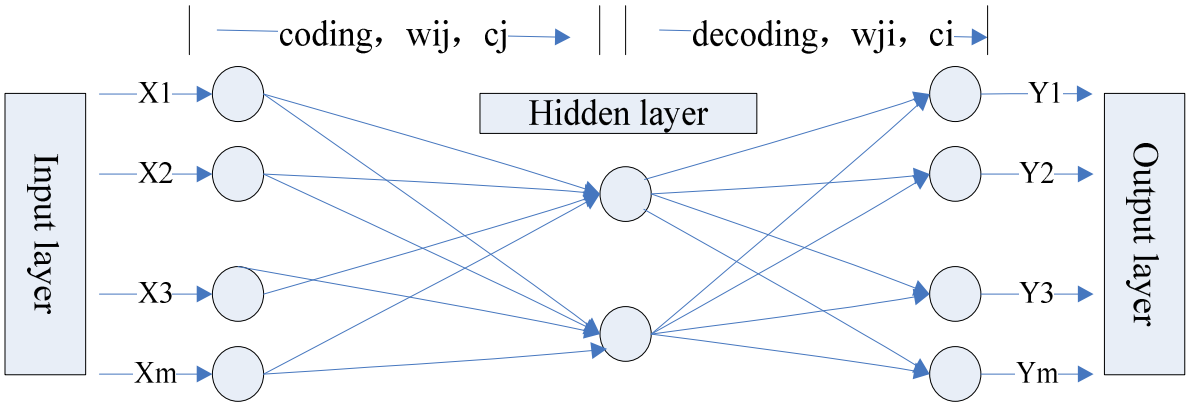

Fig.1, Three-layer feedforward BP neural network compression model

The input data of remote sensing image division and sample learning: image block of N×N pixels is divided into some same image blocks of P×P pixels. Each pixel point of the image block corresponds to an input/output neuron. The neural network selects P×P original image block as a sample by a random way. The sample repeats self-learning and self-organizing, and constantly corrects connection weights and thresholds between neurons, and which ultimately make the error between output values and desired output values of remote sensing image to a minimum. In this case, the hidden layer neuron vector is compression image data, the output layer neuron vector is reconstructed image data. Finally, the three-layer feedforward network will be used as a model of FPGA design. Input / output data model is shown in Fig.2.

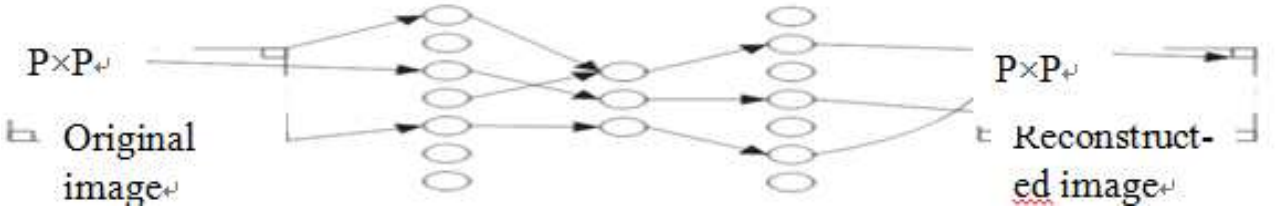

Fig.2, Input / output data model

BP neural network algorithm: Fig.1, Select a set of input values in the input layer, and then calculate the output values of hidden layer and output layer.
The j-th output value of hidden layer neuron:

$$h_j = f\left(\sum_{i=1}^{m} w_{ij} x_i + c_j\right), 1 \le j \le I \tag{1}$$

The i-th output value of output layer neuron:

$$y_i = g\left(\sum_{j=1}^{I} w_{ji} h_j + c_i\right), 1 \le i \le m \tag{2}$$

Hardware design principle of remote sensing image compression

Remote sensing image compression structural design. Design principle: Fig.3. First, in the compression coding process, input data of remote sensing image needs preprocessing, that is, it is divided into equal smaller blocks, data of each block will be transformed into a column vector. All column vector data need to be stored in the data buffer (fifo memory). Second, a set of input data is removed from the data buffer every time, and then forms image compressed data through BP network coding circuit. Finally, the compressed data will be stored in the compressed data buffer (fifo memory). Similarly, the compressed image forms reconstructed image through BP network decoding circuit.

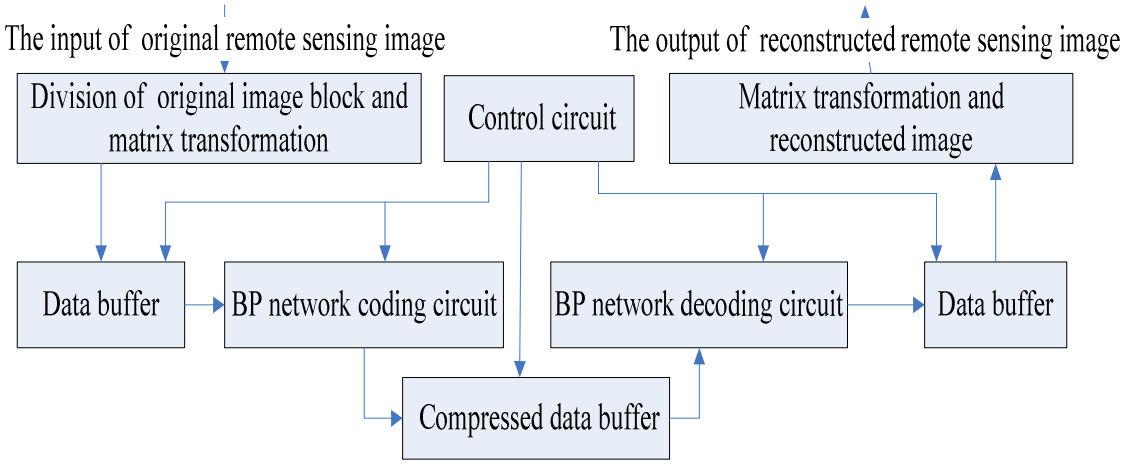

Fig.3. The overall structural design of image compression

FPGA design and implementation of BP neural network encoder. The main structure of encoder has MAC multiplier-accumulator and LUT lookup table. Fig.4, the input layer has four input values (x1, x2, x3, x4), the hidden layer has two output values (y1, y2). First, all weights are loaded from an input w, and shifted to each register according to the order, which reduces the number of chip pins and makes the chip integration become higher. And the corresponding weights and input values are multiplied and accumulated, the final results are output by LUT.

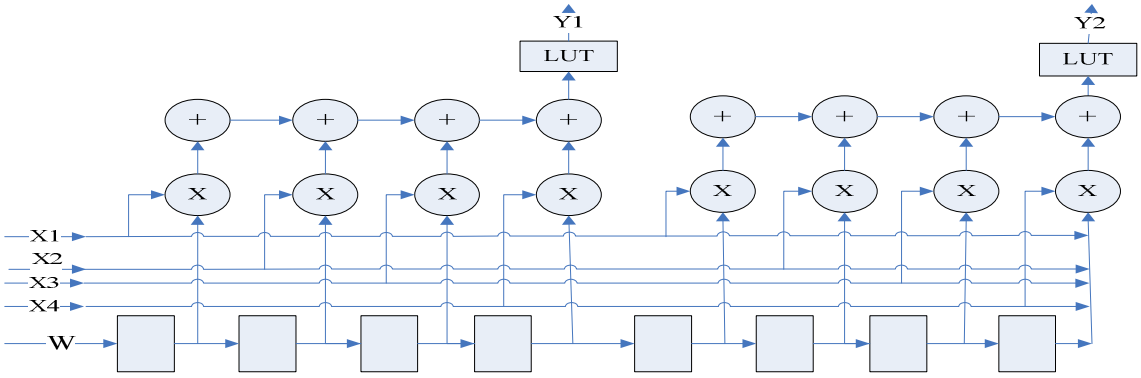

Fig.4,BP neural network coding structure

Waveform simulation of BP neural network encoder core circuit is shown in Fig.5. The input signal has a clock signal (clk), four input values (x1, x2, x3, x4), eight weights (w) which need eight registers to store. The input values and weights are 8-bit signed binary signal. The output signal has coding output values(y1, y2), test output signal (test) which checks all weights into these registers and outputs coding result.

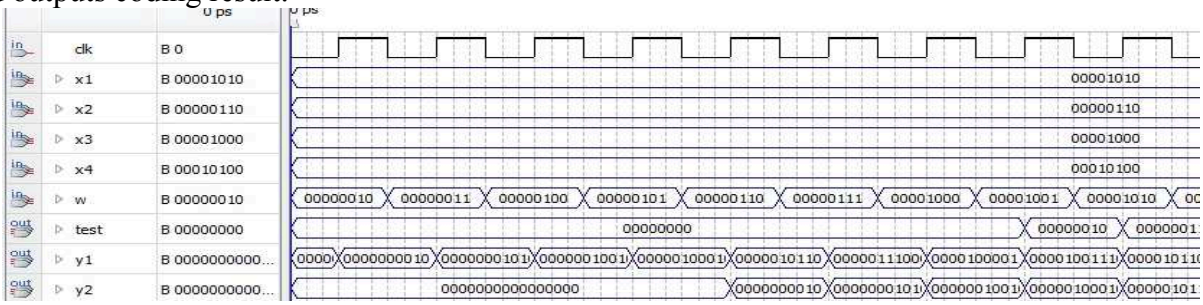

Fig.5, Waveform simulation of BP neural network encoder core circuit

The compression encoder calculates y1= 0000000100111010, y2 = 0000000010001010, that is, the simulation is correct. Then this paper does 4 times, 8 times, 12 times, 16 times compression experiments for remote sensing image. Conclusions: Table 1, compared with the traditional image compression encoders, less than 8 times, compression effect of BP neural network encoder has not

obvious advantages, however, more than 8 times, it has better compression effect. Therefore, transmission and storage of the compressed data have higher reliability and speed. Compression effect of the encoder based on FPGA has certain advantages.

Table 1 Compared with similar traditional encoders

Parameter	Less than 8 times	More than 8 times	Reliability	Speed
The encoder	Good effect	Better effect	Higher	Faster
Traditional encoders	Good effect	Poor effect	Lower	Slower

Conclusion

This paper studies and designs key technologies of remote sensing image compression based on three-layer BP feedforward neural network, and uses FPGA technology to design an encoder based on three-layer feedforward BP neural network. Compared with similar conventional encoders, the encoder has a higher compression ratio, more simple structure, good reconfiguration, higher security and speed. So the study in this paper has some theoretical values in the field of image compression.

Abstract. In a vision-based system for mobile robot/human localization in the environment, extracting feature from images and image matching are important for the final results. Although there are many algorithms for image matching, they are not fit for this system. A new method is designed to improve image matching effect.

Introduction

In a vision-based system for mobile robot/human localization[1,2,3] in the environment, a fixed camera is used to supervise the environment where the robot works and moves around. Usually the robot motion is fixed, so the human target is needed to be estimated. The human and robot relative positions are estimated in the mobile robot frame by visual information. The probability of an accident is calculated by deriving a set of positions and relative velocities[4]. In such a system, extracting feature from images and image matching are important for the final results. There are several widely used algorithms for feature extraction. Features of an image usually are contours, straight lines and points. After extracting features from images, the next task is to match these features. Image matching is also a basic problem in the field of computer vision, such as object recognition, image stitching and motion tracking.There are many solutions for the matching problems,e.g. Random Sample Consensus[5] (RANSAC). The condition, on which RANSAC can fairly estimate the model, is contrast to the one in our system. With the general idea of RANSAC, a new method to eliminate incorrect matches is introduced.

Background and Related Work

RANSAC is an iterative method to estimate parameters of a mathematical model from a set of observed data which contain outliers. It is a non-deterministic algorithm in the sense that it produces a reasonable result only with a certain probability, with this probability increasing as more iterations are allowed. An advantage of RANSAC is its ability to do robust estimation of the model parameters, i.e., it can estimate the parameters with a high degree of accuracy even when amount of outliers are present in the data set. A disadvantage of RANSAC is that there is no upper bound on the time it takes to compute these parameters. When an upper time bound is used (a maximum number of iterations) the solution obtained may not be the optimal one, it may not even be one that fits the data set in a good way. A reasonable model can be estimated by RANSAC only with a certain probability, a probability that becomes larger the more iterations that are used. Another disadvantage of RANSAC is that it requires the setting of problem-specific thresholds.RANSAC can only estimate one model for a particular data set. As for any one-model approach when two (or more) models exist, RANSAC may fail to find either one.

Solution

Although RANSAC is robust to estimate the model parameters, and with a high probability to find the correct one, it has one condition that the correct matched points are in a high proportion in all matched points. And there should be more candidate matched points as input. If the missed matched points are the majority, RANSAC can not find the correct model with a high probability and the consensus will be a set of miss matched points.

The condition, on which RANSAC can fairly estimate the model, is contrast to the one in this project. With the general idea of RANSAC, a new method to eliminate incorrect matches is introduced.

Because the reconstruction of the model from 2D image to 3D world is a rigid-body transform, the distance between each two points, no matter it is in the model or in real world, is the same during rotation and translation. The proportion between the distance in model and the distance in real world is nearly the same if the matches are correct. So there is an algorithm based on the proportion of the distances among all matches.

There are some assumptions to be satisfied for this method:

1. The reconstruction of the model from 2D image to 3D world must be a rigid-body transformation. Otherwise the distance of any two points can change during the motion.
2. There should be not too few correct matched points among all matches.

The input of the proposed method is a set of matched points between the model and the captured image. The output is a set of correct matches. The method is depicted as follows:

1. Pick up all matched points and eliminate duplicated points.

Assuming the matched points in model are in the set S_M, and the correspondent matched points in matched image are in the set S_I. The definitions of the two sets are:

$$S_M = \{{}^M P_1, {}^M P_2, \ldots, {}^M P_i, \ldots, {}^M P_n\},$$

$$S_I = \{{}^I P_1, {}^I P_2, \ldots, {}^I P_i, \ldots, {}^I P_n\},$$

where ${}^M P_i$ is a point in model matched to the point ${}^I P_i$ in captured image. The entropies of the two sets are the same. The duplicated matches mean that the value of ${}^M P_i$ is the same as the value of ${}^M P_j$ while the correspondent ${}^I P_i$ is the same as ${}^I P_j$ and $i \neq j$.

There could be many duplicated matches with the same point in model and correspondent matches in captured image. We have to delete all such kind of data to make sure all the rest data are distinct to each other.

2. Pick up one point in model and compute the Euclidian distance between this selected point to the other points in model. The Euclidian distance in model ${}^M D_{ij}$ is defined as:

$${}^M D_{ij} = \sqrt{({}^M P_i.x - {}^M P_j.x)^2 + ({}^M P_i.y - {}^M P_j.y)^2}, \quad (1)$$

where $i \neq j$, and $i, j = 1, \ldots, n$.

3. Do the same calculation as in step 2 with the correspondent point in captured image. A set of distances between one point and the others are computed. The definition of Euclidian distance in image is defined as:

$${}^I D_{ij} = \sqrt{({}^1 P_i.x - {}^1 P_j.x)^2 + ({}^1 P_i.y - {}^1 P_j.y)^2}. \quad (2)$$

4. Calculate the proportion P between this distance in image and the correspondent distance in model.

For example, we have the distance ${}^I D_{12}$ of point **1** and point **2** in model image, and the distance ${}^M D_{12}$ between the matched points in captured image **1'** and **2'**. The proportion PP_{12} is ${}^I D_{12} / {}^M D_{12}$ (or ${}^M D_{12} / {}^I D_{12}$depends on the threshold you choose). These calculated proportions are in the set S:

$$S = \lfloor PP_{12}, \ldots, PP_{ij}, \ldots, PP_{n,n-1} \rfloor,$$

where n is the number of the calculated proportions in set S, and $i \neq j$.

5. Pick up one proportion PP_{ij} in S to calculate the difference between this proportion and the other proportion PP_{kl} in S where $ij \neq kl$.

If there exists a difference less than a desired threshold t, put these point numbers (which consist of the distances in model as i, j) into the set S^*. Recursively select proportions until S is empty.

6. Repeat step 2 to step 5 until all the matched points are calculated.

7. Find the point which identified in S^* most frequently. This point is regarded as a confident point which we believe is the correct match.

8. Compare this point with the other points in S^*, to make sure that the incorrect points are removed.

The set S^* contains all the possible models. Among these models, some are incorrect. But these incorrect models are generated by the previous procedures. This may be caused by the symmetric model which generates the same symmetric features on both sides of the symmetric line of the model. This kind of situation will be described in chapter 5. So we need to remove the wrong matched points. One possible method is to compare these missed matches with the most confident match. The points in model should be in the same relative position of the points in image. For example, assuming the directions of the model and the target are the same, and there is a match AB with point A in model and point B in image, and the most confident match CD with point C in model and point D in image. If A is top-left of C in model, B should be top-left of D in image when the match CD is correct. Otherwise, CD is an incorrect match and should be removed from set S^*.

This method is simple to understand and implement compared with RANSAC. There is no need to generate the transform matrix. It is not necessary to estimate a model to make other points to fit for this model.The time complexity of this method is $O(N^2)$. N is the number of matches. It is very fast when N is small. Compared with RANSAC, this method can pick out more correct matches. Because RANSAC works well when there is a large number of matches and the minority of matches are missed ones. But in our visual-based system, there are fewer matches and some of them are missed matches. So this method works well in this kind of condition.

The disadvantage of this method is that it can not recognize correct matches if they are too few among all matches. After all, this method is more suitable for the condition of our vision system.

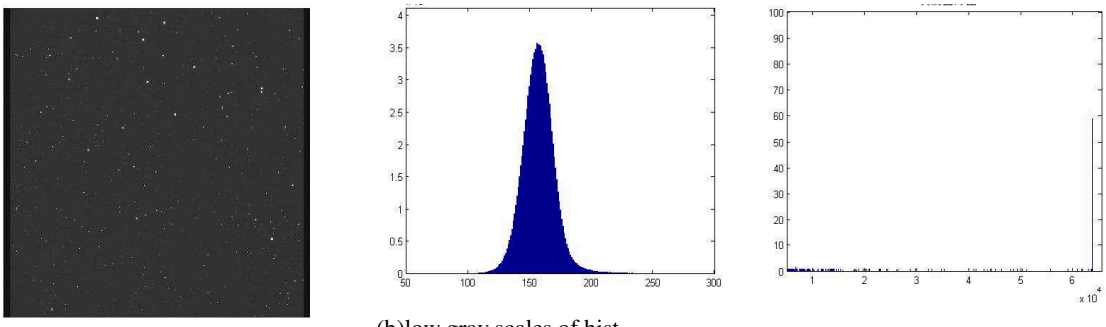
Keywords: bright stray light suppressed, targets submerge, background subtraction, target pixel extraction

Abstract. The space-based visible observation imaging platform for sky targets is influenced by many factors, a serious factor is the light of background too bright. A image with the bright stray light background has some high gray areas those may submerge the targets info. Aimed at the shortcomings of traditional background removal method in target extraction under the bright stray light background, according to the differences of bright stray light background and sky targets imaging characteristics, this paper has made some research of the algorithms about how to remove the bright stray light background but not delete the targets info. The algorithm we got that give us great results will be shown in the paper. It solves the problems of the bright background light removal and greatly retain the targets info which submerged in the bright areas.

Starry-sky image quality depressed by highlight background

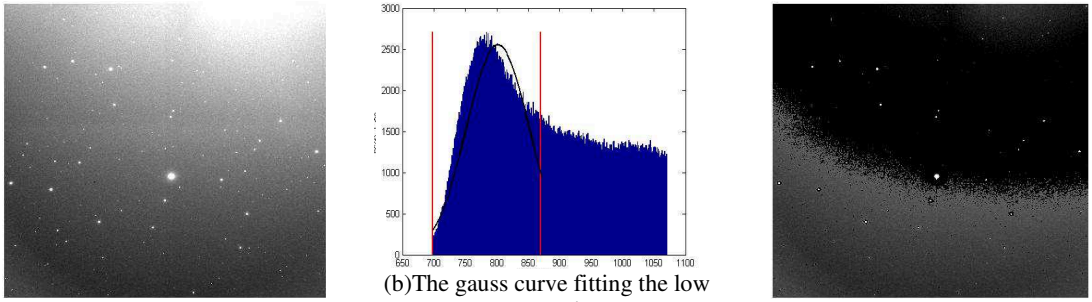
Through the analysis of starry-sky image histogram, we found that the histogram distribute according to gauss curve, just as the figure 1(b) show us. The objects and stars have high gray scales but the background have low gray scales. Preference 1 has shown us how to fit the histogram as gauss curve, then get the background average and standard variance. Make $Threshhold = u + c * \sigma$ to subtract the image background so as to avoid the influence of the background. u is the average of background gray scales, c is a constant, σ is standard variance.



(a)starry-sky image (b)low gray scales of hist (c)high gray scales of hist

Figure 1 Starry-sky image gray histogram without highlight background

Unfortunately, because of the exist of bright stray light background in the starry sky, the gauss threshold cannot make the image background subtraction great enough to satisfy the need of stars detecting algorithm. Figure 2(c) gives the background subtraction result of a starry-sky image by gauss threshold without amelioration, where μ= 801.6136, σ= 49.7033, Figure 2(b) shows the gauss curve which we tried to fit the histogram gray scales.



(a)starry sky image with highlight background

(b)The gauss curve fitting the low gray scales

(c)The background subtracting starry-sky image

Figure 2 Parameter estimation of starry-sky image by gauss curve fitting algorithm

The histogram of starry-sky image with bright stray light background doesn't fit the distribution of gauss curve any more, there are a lots of middle gray scale pixels between the background gray scales and objects gray scales, which is the influence of the bright stray light background. The background average value and standard variance will be a little small if using the gauss algorithm to fit the gray scales directly, consequently, the binary image based on gauss threshold will exist a lot of "1" area pixels which will affect the objects info detection.

Bright stray light restrain algorithm

For starry-sky images like figure 2, objects and stars info can not be detected effectively because of the background can not be entirely estimated. For this reason, the paper restrained the starry-sky background firstly, then tried to fit the background gray scales as gauss curve distribution. The steps:

(1)Processing the starry sky image with average filter. The template of the filter is $n\times n, n=3,5,7$ for this paper, $n=3$.

(2)Do morphologic operation to the step(1) images.

(a)Setting the radius, create the morphologic template.

Calculate the distant R of the template coordinate and the focus coordinate, make the value of the template coordinate "1" if the distance is less than R ,else "0".

$$dis[(x,y),(x_0,y_0)]=\sqrt{(x-x_0)^2+(y-y_0)^2} \qquad x,y=0,1,2,\cdots 2R \qquad (1)$$

$$if\ \ dis <= R \qquad x_0,y_0=R$$

$$temp(x,y)=1$$

$$else$$

$$temp(x,y)=0.$$

$(x,\ y)$ is the template coordinate and (x_0,y_0) is the focus coordinate, $temp$ is the matrix of template in formulae (1).

(b)Making the erode operation with template

Processing the image pixel $r(x,y)$ just follow the steps hereinafter:

Check the pixels with the coordinate which has the distant from the focus coordinate of the template less than *R* one by one, subtract the template value from the pixels value and record the numbers. Make the least value as $r(x,y)$.

(c)Operate twice with morphologic dilating operator of the template

Morphologic dilating operator is the counter operator of eroding operator, which add the template value and the the pixel value, and then make the largest value as $r(x,y)$.

(d)Another erode operation

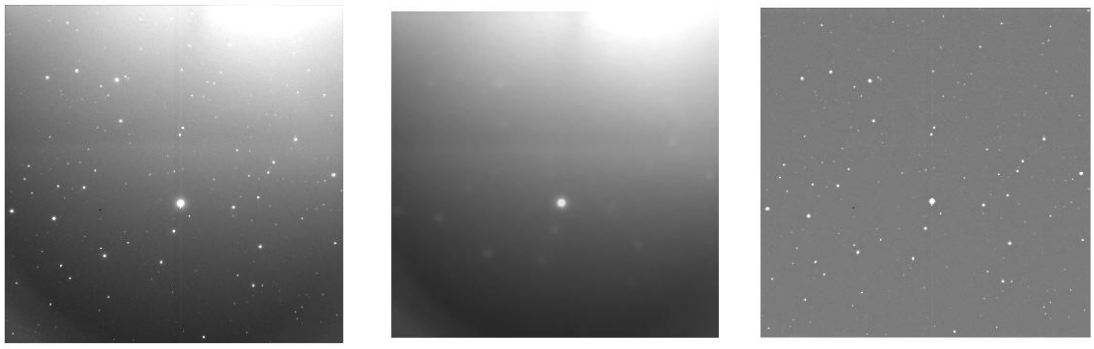
(3)Subtracting the bright stray light after morphologic operation

(a)Calculate the average of the starry sky image, record as $avgval$.

(b)Add the pixels value of the origin image and $avgval$,then subtract the pixels values of image after morphologic operation and the last values of the matrix is the image without the stray light.

The results of experiment

The gauss curve fitting algorithm can estimate the parameters of the image which without bright stray light background, but parameters of images with the bright stray light background can not be rightly estimated by gauss curve fitting algorithm. This paper has brought forward the bright stray light restrain algorithm, the results of experiment as the figure 3 shows confirm the restrain algorithm can bring the great image matrix values those can rightly be fitted by gauss curve fitting algorithm.

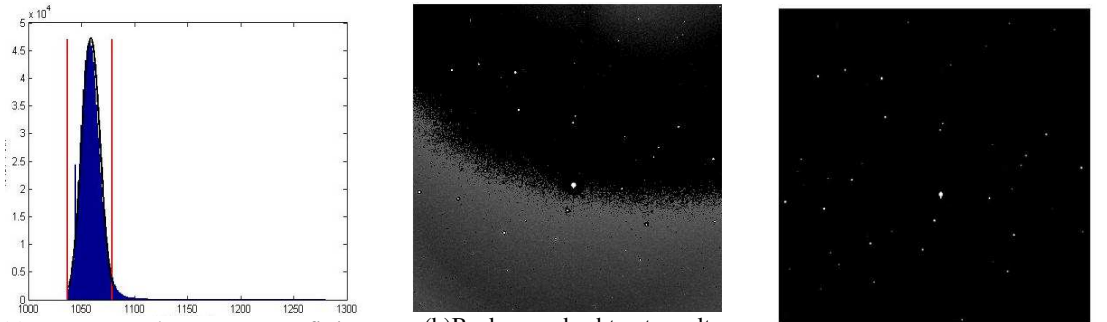


(a)Average filter result (b)Morphologic operate result (c)Subtract bright stray light result

Figure 3 Bright stray light restraining and subtracting results

The bright stray light restrain algorithm can bring the great effect as Figure 4 shows, where $\mu = 1058.9, \sigma = 8.5047$.

Figure 4 shows that we can get better objects and stars detecting results if the image with bright stray light background can be operated by the restrain algorithm of this paper.



(a)Low gray scales gauss curve fitting after background restrain (b)Background subtract result without stray light restrain (c) Background subtract result with stray light restrain

Figure 4 The effect of restrain algorithm

Summary

The exist of bright stray light may effect the imaging of objects and stars, it can make stars and objects in the highlight area hard to detect. This paper has researched out the bright stray light restrain algorithm based on do not effect the stars and objects pixels info. The result of experiment has shown the advantage and reliability and practicability of the algorithm to the starry sky images with bright stray light background.

Keywords: Wireless Body Area Network (WBAN); Channel Modeling; Time Variant Channel Fading; Channel Time-Coherence.

Abstract. In order to build WBAN devices and design WBANs, it is imperative to study the characteristics of WBAN channel and model the channel accurately. WBAN channel models are so different from the traditional mobile channel models and there are few publications on them. In this paper, we studied the statistic characteristics of the WBAN channel based on the IEEE 802.15.6 models. We focus on body surface nodes to external nodes, simulated the path loss models on 820 MHz and 2.36 GHz at both LOS and NLOS situations. We also used the Gauss model to fit the statistic results of the path loss and obtained coefficients of Gauss model.

Introduction

As an emerging application in short range wireless radio technology, WBANs have received a growing interest in scientific and industrial communities recently. It can be used for promising prospects across a range of applications, including military services, sport monitoring, personal entertainments, especially the healthcare. It provides an economical solution to rising costs in the healthcare system and promises unobtrusive ambulatory health monitoring for a long period of time and provide real-time updates of the patient's status to the physician.

An important step in the development of a wireless body area network is to design and evaluate specifications of PHY for WBANs, suitable channel models are necessary. However, due to the complexity of the human tissues structure and body shape, it difficult to drive a simple path loss model for WBAN.

There are been various analytical and experimental studies of propagation characteristics for WBANs during the past few years [1,2]. The IEEE 802.15 task group 6 was established in the year of 2007 to develop communication standard optimized for low power devices and operation both in-body and on-body. The channel modeling subgroup released the final channel model for WBAN in July 2010 [3].

In order to find more realistic channel models for WBANs, in this paper we studied IEEE802.15.6 WBAN channel models [3] based on statistical analysis method and used MATLAB software to do computer simulation. The scenarios we studied are body surface to external CM4, including scenario S6 and S7 situations for both LOS and NLOS circumstance. We did simulation at 820 MHz and 2.36 GHz medical frequency band. We statistic studied the characteristics of the path loss models and used the Gauss model to fit the statistic results of the path loss.

The remainder of the papers is organized into three sections. 'Model Description' presents channel models used in this study. Simulation results and corresponding parameters and coefficients are given in "Simulation Results". The final section concludes our work.

IEEE 802.15.6 Channel Models

In November 2010, according to the positions of transceiver nodes, the TG6 defined the WBAN channel models which covering seven scenarios [3]. They are Implant to Implant, Implant to Body

Surface, Implant to External, Body Surface to Body Surface (LOS), Body Surface to Body Surface (NLOS), Body Surface to External (LOS), and Body Surface to External (NLOS) scenarios. We have studied the first five scenarios in our previous papers. In this paper, we focus on Body Surface to External both at LOS and NLOS situations.

The details of experimental method and equipment used for these measurements can be found in [4]. This section presents summarizes of the channel path loss results. The transmitter is placed on the chest and the receiver is away from the body with various distances as outlined. Each channel measurement is of approximately 5 s in duration and consists of multiple 40 ¹s blocks that are separated in time by 2.5ms.

The channel path loss $PL(t)$ at a given time t is given by [4]:

$$PL(t) = P_{tx} - P_{rx}(t) + G_{amplifiers} - L_{cable} \quad (1)$$

where P_{tx} is transmitted power, $P_{rx}(t)$ is the RMS received power at time t, $G_{amplifiers}$ is amplifier gain, and L_{cable} is cable loss. The path loss sometime may decrease with increased distance in some measurements, but the general trend is increase. Table. 1 summarizes the average path loss results, Table. 2 summarizes the path loss variation. The transmitter was placed on the right wrist and the receiver was stationary.

Table. 1 Average Path Loss (dB)

		LOS				NLOS			
	Distance (m)	1	2	3	4	1	2	3	4
820MHz	Standing	47.84	65.29	65.72	70.72	60.27	65.60	70.94	74.43
	Walking	48.12	57.42	59.02	58.65	51.85	57.51	63.19	62.51
2.36GHz	Standing	59.78	73.04	67.20	63.61	69.30	72.62	73.72	74.40
	Walking	55.68	58.90	61.92	65.18	58.26	60.89	61.92	63.15

Table. 2 Path Loss Variation(dB)

		LOS				NLOS			
	Distance (m)	1	2	3	4	1	2	3	4
820MHz	Standing	0.49	0.77	1.09	1.13	0.34	0.81	1.42	1.25
	Walking	20.59	9.28	21.18	14.48	17.78	16.73	16.63	12.75
2.36GHz	Standing	1.38	1.36	3.95	0.81	2.11	0.84	0.92	1.36
	Walking	24.71	24.23	20.21	15.52	24.62	21.83	20.05	16.54

The path loss of NLOS is larger than the LOS situation, because the signal is shadowed by the human body.

Simulation Results

In this section, we give the simulation results of nodes on body surface to body surface external nodes CM4 (Scenario S7 & S8) for 820MHz and 2.36GHz.

D. CM4 for 2.36GHz （NLOS）

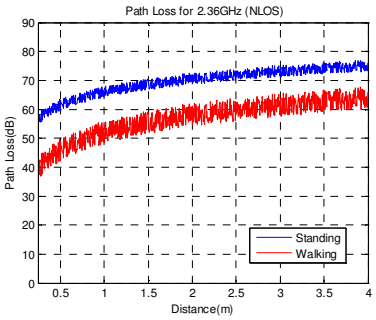

Fig. 10 Path Loss for 820MHz

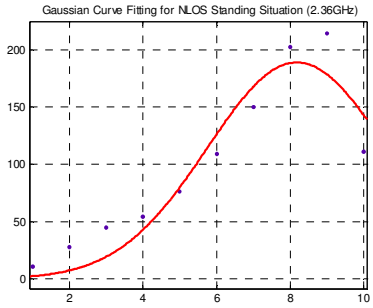

Fig. 11 Curve Fitting for Standing Situation

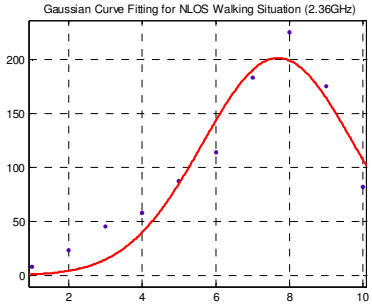

Fig. 12 Curve Fitting for Walking Situation

Fig.1, Fig. 4, Fig.7 and Fig. 10 are path loss curves for LOS 820MHz, NLOS 820MHz, LOS 2.36GHz and NLOS 2.36GHz respectively. Fig. 2, Fig. 3, Fig. 5 and Fig. 6 show Gauss curve fitting of the statistic characteristics of path loss for LOS 820MHz of standing situation, LOS 820MHz of walking situation, NLOS 820MHz of standing situation and NLOS 820MHz of walking situation. Fig. 7, Fig. 8, Fig. 11 and Fig. 12 show Gauss curve fitting of the statistic characteristics of path loss for LOS 2.36GHz of standing situation, LOS 2.36GHz of walking situation, NLOS 2.36GHz of standing situation and NLOS 2.36GHz of walking situation respectively.

We use the Gauss general model: $f(x) = ae^{-\left(\frac{x-b}{c}\right)^2}$ to fit the statistic characteristics of path loss. The coefficients (with 95% confidence bounds) and the goodness of fit are shown in the Table 3.

Table 3. Coefficients of Gauss model and the Goodness of fitting

			Coefficients of Gauss model			Goodness of fitting			
			a	*b*	*c*	SSE	R-square	Adjusted R-square	RMSE
860MHz	LOS	Standing	307	14.1	7.502	1061	0.9787	0.9726	12.31
		Walking	193.8	8.185	3.247	9316	0.8172	0.765	3648
	NLOS	Standing	188	8.674	3.851	4941	0.8944	0.8642	26.57
		Walking	205.8	7.383	2.785	2727	0.9443	0.9283	19.74
2.36GHz	LOS	Standing	210	7.577	2.674	3942	0.921	0.8985	23.73
		Walking	207.6	7.753	2.733	4898	0.9013	0.873	26.45
	NLOS	Standing	188.9	8.185	3.438	4361	0.9029	0.8752	24.96
		Walking	201.4	7.694	2.905	3965	0.9174	0.8938	23.8

Conclusion

Channel models of WBANs can be used to understand wave propagation in and around the human body and they are essential for antenna design, protocol design and the design of front-end RF hardware and modulation schemes. In order to obtain a sophisticate wireless technology and design WBANs with high efficiency and high reliability, the knowledge about the propagation characteristics of WBANs must be thoroughly investigated. In this paper, we studied the path loss models of body surface to external CM4 (Scenario S6 & S7) for 860MHz and 2.36GHz and obtained coefficients of Gauss model.

Research and Solution on Bottleneck Problem in Zigbee

Jianping Zhang, Xiaoling Zeng

Chongqing Creation Vocational College, China

mybaoer@126.com, zenxiaoling123@163.com

Keywords: Converge Cast, Bottleneck, Scheduling.

Abstract. When the root is collecting data at a tree-based network, more upper nodes is usually with more packets usually. We called this bottleneck problem. The goal of this paper is to solve the bottleneck problem in ZigBee tree network. We use The Beacon-Only Period Approach which has been proposed by IEEE802.15.4b to avoid the collision caused by beacon frame. Moreover, we propose a centralized algorithm (TDMLF) that enables the nodes to fully use the GTS transmission. TDMLF not only avoides the hidden node problem which occurs in IEEE802.15.4, but also enables the entire network to achieve a more effective parallel transmission. Simulation results show that the TDMLF algorithm effectively reduces the bottleneck problem, and thus achieves a high delivery ratio. Moreover, because of no collision, the TDMLF also reduces the waste of time and energy by retransmission.

Introduction

The ZigBee standard provides three kinds of network topology: star, tree and mesh. In order to enhance expandability and apply electric power effectively, this paper selects cluster tree network for discussion. When network performs data collection, there is higher flow and bottleneck problems occurs easily because inner layer nodes must help outer layer nodes deliver data. When data collection is carried out for ZigBee cluster tree, there is no handshaking mechanism in IEEE802.15.4 standard. Thus, when the number of child nodes of ZigBee Router (ZR) is large, competition will be quite fierce so that ZR fails to receive data effectively and the bottleneck problem occurs. To address this problem, this paper puts forward a new scheduling method, i.e. Top Down Maximum Load First (TDMLF), and uses Guaranteed Time Slot (GTS) that will not cause collision to transmit packets.

A ZigBee network consists of three different types of nodes: ZigBee Coordinator (ZC), ZigBee Routers (ZRs) and ZigBee End Devices (ZEDs) [1]. IEEE802.15.4b task group has two main jobs: explaining ambiguous parts in the IEEE802.15.4 standard and improving shortages of the standard [2]. Reference [3] puts forward scheduling algorithm which transmits nodes at the bottom layer first and make data achieve the effect that they are transmitted from bottom to upper layer. Thus, the delay time from the moment when nodes transmit data to the time at which ZC receives data can be reduced. However, the method sets the time at which all nodes are awake as the same. If so, nodes on the upper layer, which hope to help nodes on the lower layer to transmit data, may suffer the bottleneck problem. Reference [4] puts forward a new Active Period collocation method that is called Time Shift Grouping Access (TSGA). To make ZC be able to receive data constantly during the whole Beacon Interval (BI) at which beacon frames are transmitted, the method divides the whole network into two sub-trees. When the first sub-tree transmits data to ZC, the second sub-tree can make full use of this time to collect data; vice versa. This transmission mode is similar to D-MAC [5]. However, length of the activity interval of each node in this method may not be able to accord with their flows. To ensure each ZR has enough time to transmit all data that need be delivered, TDBS proposes an approach in which work cycle can be decided according to data size [6]. In TDBS, the work cycle of each ZR is exponential power of 2 and must be larger or equal to sum of all sub-ZRs. When ZC extends its work cycle to 1, its activity interval will occupy the whole BI, which makes the activity interval of ZRs on the first layer fail to be staggered from ZC. This will disobey principles of the Time Division Approach.

In order to solve the bottleneck problem, this paper puts forward a new scheduling algorithm, i.e., TDMLF. In TDMLF, ZC will configure appropriate GTS according to flow of each node, which makes nodes that have higher flow can obtain more opportunities of transmission.

The Algorithm

This paper considers environment of periodic return and assumes that ZC knows topology and interference conditions of the whole network. The bottleneck problem is not serious in network with small scale and flow is not serious, so this paper focuses on analyzing network with large scale and flow. Our designed protocol adopts the Beacon-Only Period (BOP) approach that all nodes can enter the activity interval simultaneously, as shown in Figure 1.

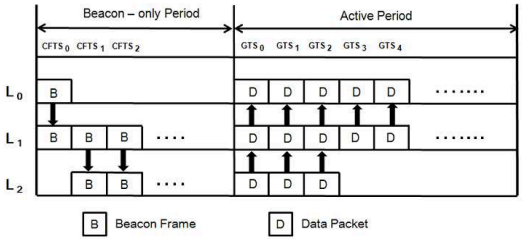

Fig. 1 Proposed superframe format

In Fig. 1, one BI is divided into two parts, i.e., BOP and Active Period, which is composed of Contention Free Time Slots (CFTS) and GTS, respectively. It is set that the time that ZC takes to implement one data collection is one BI, it will imply that ZC cannot finish all data collection within one BI and the bottleneck problem will occur if the time at which nodes generate a group of data is too short. To reduce occurrence rate of this situation, we aim at increasing parallelization transmission and making ZC can receive data constantly in order to shorten length of BI.

In BOP, ZC allocates CFTS to each ZR, which makes it be able to transmit Beacon frames in CFTS that it belongs to instead of causing collision. The algorithm used to allocate CFTS is shown as follows.

Algorithm 1: CFTS allocation
Step 1, ZC sorts all ZRs in the network according to following conditions:
(1) Height of sub-trees (in descending order)
(2) The number of ZRs (in descending order)
(3) ID (in ascending order)
Step 2, ZC checks whether ZRs that have been sorted accord with following specifications or nor:
(a) Have received but not transmitted Beacon frames
(b) Neighboring father nodes are not allocated with CFTS
(c) Neighbors of sub-nodes are not allocated with CFTS
If the ZR passes the inspection, it can be allocated with CFTS.
Step 3, if all ZRs are allocated with CFTS, end the algorithm. Otherwise, i+1 and return to Step 2 to continue implementation.

The Beacon-Only Period Approach proposed by IEEE802.15.4b will cause much collision during Active Period. To avoid collision, we let all nodes transmit data by using GTS. However, in the standard, length of a GTS is (1/16) *k (k is a positive integer from 2 to 15) of the activity interval. However, the length is too large and it is not divided specifically. In this paper, we fix the size of a GTS as the time that complete transmission of a data packet needs. This period of time contains four parts, including transmitting a packet, waiting for Ack, time used to transmit Ack and a LIFS. In detail, the LIFS directs at making MAC layer have time to process data received from PHY layer. Thus, when a packet is received, a period of waiting time about LLIFS is needed. At initialization of network, ZC will implement TDMLF algorithm proposed by us to allocate GTS transmitted by all nodes in the network. The algorithm about allocation GTS is shown as follows.

Algorithm 2: TDMLF algorithm
Step 1: ZC sorts all ZRs in the network according to following conditions:
(1) The number of hops of ZC (in ascending order)
(2) The number of packets in buffer (in descending order)
(3) ID (in ascending order)
Step 2: check whether ZRs that have been sorted accord with following specifications or nor:
(a) There are packers that wait for being transmitted in buffer.
(b) All neighboring sub-nodes are not allocated with GTS.
(c) Father nodes and neighbors of father nodes are not allocated with GTS.
If the node passes the inspection, it can be allocated with GTS and the number of its buffer packets will reduce by 1 and the number of its buffer packets in its father nodes will increase 1.
Step 3: if ZC receives data of all nodes, end the algorithm. Otherwise, i+1 and return to Step 1 to continue implementation.

Simulation and Analysis

To verify the foregoing algorithms, we carry out simulation to comparie the two protocols TDMLF and TDBS By comparing the following three indexes, performance of the network is measured.

Goodput (kbps): average amount of the information that ZC receives each second correctly.

Delivery Ratio (%): the ratio of data generated by all nodes and transmitted to ZC successfully.

Power Consumption per Packet (mJ): the electric power consumed by transmitting one packet to ZC averagely.

Artificial network scene is in a 100*100m^2 square area. 100 ZRs and 200 ZEDs are deployed evenly and randomly [7]. To make ZED help us detect a larger scope, we deploy 88 ZEDs in the scope of a hop, which is obtained via extending original area outward, as shown in Fig. 2. Draw a grid line each 10 meters on x axis and y axis. Besides, node reservation is arranged at intersection of grid lines. However, each node and grid point will have a random displacement about 0-3 meters at x axis and y axis, which makes topology different when simulation is carried out each time.

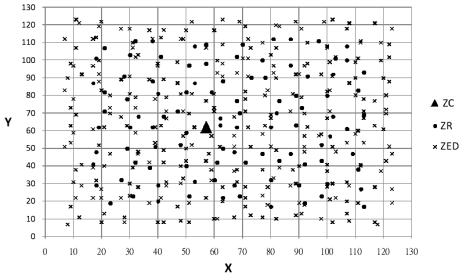

Fig. 2 Network stationing method

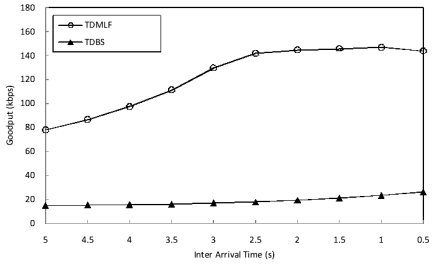

Fig. 3 Date size received by ZC under different flows

Parameter settings used by the simulation are shown as follows: *Cm*=6, *Rm*=4 and *Lm*=10, the maximum communication distance among nodes is 15m, size of data packet is 127 Bytes and rate of data transmission is 250kbps. Besides, power consumption of a transceiver follows setting of CC2420 single chip [8], current under a sending mode is 17.4mA, the current under a receiving mode is 18.8mA, the current under an idle mode is 426uA and the current under a power saving mode is 20uA. Besides, simulation time is 600s. All simulation data are average value of 20 simulations.

IN TDBS, there is no detailed description about how ZR can receive data of each sub-node in the activity interval. To compare with TDMLF fairly, we amend TDBS: each ZR also uses GTS to transmit data, while 7 GTSs can be allocated to different sub-nodes at least according to standard specifications. In order to ensure each ZR can be allocated with GTS, we let father nodes allocate minimum GTS (2 slots) to each ZR.

Fig. 3 shows data size received by ZC under different flows. According to the figure, it can be found that there is much difference between TDBS and the proposed TDMLF algorithm. The reason for this is that TDBS is subject to limitations of the standard for length of GTS. Thus, length of the allocated GTS cannot accord flow of each node accurately. If a certain sub-node fails to transmit all of its data, the bottleneck problem will occur. If a certain sub-node sends all of its data too early, wasting

of resources will be caused. In addition, the work cycle of ZC is limited to be less than 1/2, which reduces growth of Goodput to a large extent. In TDMLF, Goodput will increase with traffic load. Nevertheless, when inter arrival time reaches 2.5 seconds; increase in Goodput will tend to be mild.

Fig. 4 displays the ratio at which data are passed back to ZC under different flows. According to the figure, it is shown that TDMLF can nearly reach 100% of date loopback rate before the inter arrival time is 3 seconds. Similarly, the loopback rate begins to reduce later because Goodput of ZC has been saturate.

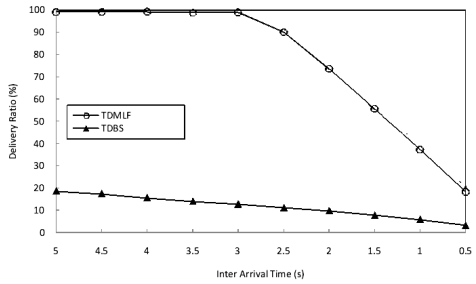

Fig. 4 Ratio of data passed back to ZC

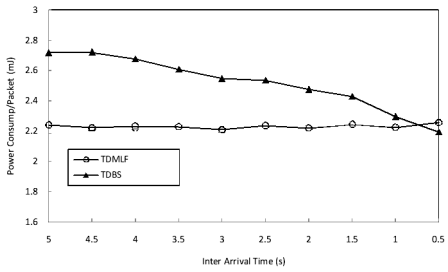

Fig. 5 Average power consumption need by transmitted a packet

Fig. 5 illustrates average power consumption need by transmitted a packet under different flows. According to the figure, we can find that TDMLF algorithm is better than TDBS. Power utilization efficiency of TDBS is in direct proportion to flow because the size of data that ZC receives from sub-ZED is small in TDBS with low flow. However, when the flow is high, ZC receives a large number of data from sub-ZEDs. Data of TDMLF algorithm is sent to ZC directly. Compared with data that are transmitted layer by layer, the power consumption needed by transmission of these data is low. Thus, average power consumption can be reduced.

Conclusions

First of all, this paper procided definition of the bottleneck problem in ZigBee tree network. To reduce the complexity of the bottleneck problem, we put forward a centralized TDMLF algorithm to make nodes by using GTS to achieve better parallelization transmission. At the same time, we re-adjusted the length of GTS, which enabled more efficient resource allocation. Simulation results showed that the proposed algorithm proposed is better than existing methods in the aspects of both data loopback rate and electricity saving efficiency. Therefore, it should be a scheduling protocol with huge potential for ZigBee cluster tree network.

Keywords: Image decomposition, linear discriminant analysis, Euler mapping, face recognition.

Abstract. This paper presents a robust but simple image feature representation method, called image decomposition based on Euler mapping (IDEM). IDEM firstly captures the orientation information by implementing arctangent operator for each pixel. Then, the orientation image is decomposed into two mapping images by executing Euler mapping. Each mapping image is normalized using the "z-score" method, and all normalized vectors are concatenated into an augmented feature vector. The dimensionality of the augmented feature vector is reduced by linear discriminant analysis to yield a low-dimensional feature vector. Experimental results show that IDEM achieves better results in comparison with state-of-the-art methods.

Introduction

Face recognition is a popular research field in pattern recognition, and has attracted much attention in many areas, such as information security, law enforcement, and surveillance. Many face representation approaches have been introduced, including holistic feature representation approaches and local feature representation approaches. The holistic representation methods take a single feature, which is extracted from the whole face image, as input for face recognition. Among them, principal component analysis (PCA)[1] and linear discriminant analysis(LDA)[2] have become the most popular techniques for face recognition. The performance of the holistic matching methods obviously degrades with variations in expressions, poses, illumination conditions, etc. Increasing attention recently has been put into the local matching methods. The local binary pattern (LBP) [3] and Gabor wavelets [4] are two of the most popular local representation methods for face recognition. Recently, Qian et al. propose a simple but effective feature representation method called image decomposition based on local structure (IDLS) [5] . They consider decomposing an image into a series of sub-images which contain different structural information. In this paper, we propose a simple but effective local feature representation method called image decomposition based on Euler mapping (IDEM). IDEM first captures the orientation information by implementing arctangent operator for each pixel. After that, we obtain an orientation angle for each pixel. Then, motivated by the recent work on robust cosine-based dissimilarity measure [6], we show that a cosine-based dissimilarity measure has a functional form, which enables us to define an explicit nonlinear Euler mapping from the input space into a complex space. Each orientation image is therefore decomposed into two mapping images, which contain the imaginary part image and the real part image. For an orientation image, the imaginary part image retain the main information and smooth the higher value information, and the real part image mainly enlarges the lower value information and reduces the higher value information. Finally, each mapping image is normalized using the "z-score" method and we concatenate all normalized vectors into an augmented vector. The dimensionality of the augmented vector is further reduced by LDA to yield a low-dimensional feature vector.

Image Decomposition based on Euler mapping

Assume that we are given two images $F_j \in \Re^{h\times l}$ and $F_k \in \Re^{h\times l}$, we compute their orientation images Φ_j and Φ_k according to (1). let b_j and b_k be the D-dimensional ($D = h \times l$) vector obtained by writing Φ_j and Φ_k in lexicographic ordering.

$$\Phi = \arctan(F) \tag{1}$$

Motivated by the recent work on robust correlation-based translation estimation [6], we replace the l2-norm with the following dissimilarity measure:

$$d(b_j, b_k) = \sum_{q=1}^{p} \{1 - \cos(b_j^{(q)} - b_k^{(q)}))\} \tag{2}$$

where $b_j^{(q)}$, $b_k^{(q)}$ are, respectively, the q-th dimension column vector b_j and b_k.

Next, we will show that how to get a new mapping image by utilizing the robust dissimilarity in (2). We make the following derivation:

$$\begin{aligned} & d(b_j, b_k) = \sum_{q=1}^{p} \{1 - \cos(b_j^{(q)} - b_k^{(q)})\} \\ & = \frac{1}{2} \sum_{q=1}^{p} \{2 - 2(\cos b_j^{(q)} \cos b_k^{(q)} + \sin b_j^{(q)} \sin b_k^{(q)})\} \\ & = \frac{1}{2} \sum_{q=1}^{p} \{(\cos b_j^{(q)} - \cos b_k^{(q)})^2 + (\sin b_j^{(q)} - \sin b_k^{(q)})^2\} \\ & = \frac{1}{2} \left\| (\cos b_j + i \sin b_j) - (\cos b_k + i \sin b_k) \right\|_F^2 \\ & = \left\| \frac{1}{\sqrt{2}} e^{ib_j} - \frac{1}{\sqrt{2}} e^{ib_k} \right\|_F^2 \end{aligned} \tag{3}$$

We map the orientation vector b_j onto the complex representation $z_j \in C^p$,where

$$z_j = \frac{1}{\sqrt{2}} [e^{ib_j^{(1)}}, e^{ib_j^{(2)}}, ..., e^{ib_j^{(p)}}]^T = \frac{1}{\sqrt{2}} e^{ib_j} \tag{4}$$

The vector z_j can be thought of as the special features in complex space C. Because of (4), we coin this mapping as Euler mapping. Actually (4) is also rewritten as：

$$z_j = \frac{1}{\sqrt{2}} e^{ib_j} = \frac{1}{\sqrt{2}} (\cos b_j + i \sin b_j) \tag{5}$$

According to (5), we can get a real part mapping feature vector and an imaginary part mapping feature vector:

$$\begin{aligned} & \xi_j^{real} = real(z_j) = \frac{1}{\sqrt{2}} \cos(b_j) \\ & \xi_j^{imag} = imag(z_j) = \frac{1}{\sqrt{2}} \sin(b_j) \end{aligned} \tag{6}$$

where $\xi_j^{real} \in (0, 1/\sqrt{2}]^D$, $\xi_j^{imag} \in (-1/\sqrt{2}, 1/\sqrt{2})^D$, and the real part corresponding to the cosine function, the imaginary part corresponding to the sine function.

Given an input image F, we can compute its orientation image Φ by executing arctangent operator. The orientation image is decomposed into a real part image and an imaginary part image by implementing Euler mapping. For an orientation image, the imaginary part image (sine transformation) retain the main information and smooth the higher value information, and the real part image (cosine transformation) mainly enlarges the lower value information and reduces the higher value information.

Assume that we are given a set of n images $\{F_i\}$,we can obtain $N(=2\times n)$ sub-images $\{\Theta_i^s\}$ by decomposing image. Let Θ_i^s ($i=1,...,n; S=1,\ 2$) represents the *S*-th sub-image of the i-th sample image. Let ξ_i^s be the *D*-dimensional column vector obtained by writing Θ_i^s in lexicographic ordering. We can obtain matrix of the decomposed data $B=[\xi_1^S...\xi_n^S]\in\Re^{D\times n}$. Each mapping image is normalized using the "z-score" method. We denote by δ_i^s the normalized vector of ξ_i^s . The *q*-th dimension of δ_i^s can be calculated according to (7).

$$\delta_i^{S,(q)}=(\xi_i^{S,(q)}-\mu^{S,(q)})/\sigma^{S,(q)}\ ,\ i=1,...,n\ ,\ q=1,...,D \tag{7}$$

where $\xi_i^{S,(q)}$, $\delta_i^{S,(q)}$ are , respectively, the q-th dimension of column vector ξ_i^S and δ_i^s , $\mu^{S,(q)}=\frac{1}{n}\sum_{i=1}^{n}\xi_i^{S,(q)}$, $\sigma^{S,(q)}=\sqrt{\frac{1}{n}\sum_{i=1}^{n}(\xi_i^{S,(q)}-\mu^{S,(q)})^2}$. We can compute all D dimensions of column vector δ_i^s according to (7).

For an input image F_i , we can obtain its two normalized vectors, and concatenate them into an augmented feature vector $\chi_i=[(\delta_i^1)^T(\delta_i^2)^T]^T\in\Re^L$ ($L=2\times D$). The dimensionality of the augmented vector is reduced by LDA to yield a low-dimensional feature vector.

LDA searches for feature vectors in the underlying space that best discriminate among classes. More formally, given a number of independent features relative to which the data is described, LDA creates a linear combination of these which yields the largest mean differences between the desired classes. Mathematically speaking, for all the samples of all classes, we define two measures: 1) one is called within-class scatter matrix S_w. 2) the other is called between-class scatter matrix S_b. The goal is to maximize the between-class measure while minimizing the within-class measure. The discriminative projection basis W and eigenvalues Λ are obtained by solving the thin Linear Discriminant Analysis(LDA) eigendecomposition:

$$(S_w+\varepsilon I)^{-1}S_bW=W\Lambda \tag{8}$$

where ε is a small regularization constant (10^{-3} below) and I is the identity matrix. Thus, the original L-dimensional space is projected onto a final d-dimensional space using LDA.

Experiments

In this section, we will evaluate the performance of IDEM and compare it with some state-of-the-art methods by experimenting on Extended Yale B[7].

In the following experiments, we choose the regularized parameter in feature extraction as $\varepsilon=0.001$ in our IDEM method. The extended Yale B face image database contains 38 human subjects under 9 poses and 64 illumination conditions. All frontal-face images marked with P00 are used in our experiment, and each is resized to 96×84 pixels. Some sample images of one person are shown in Fig. 1. In our experiment, we randomly choose K samples from each class for training and the remaining images for test. Here, K varies from 4 to 20 with interval of 4. For each K, we perform 10 runs of tests for each method mentioned above. The average recognition rates and std of each method across 10 tests are shown in Table 1. The recognition results of compared methods are reported in [5]. As we can see, the recognition rates of PCA and TPLBP are relatively poor. The performances of LTP/DT, LTP plus Chi2, LDA , Gabor plus FLDA, LARK and IDLS-Distance are not very satisfying. ID-LARK,LBP+Chi2 and IDLS achieve better results than the above methods. However, in this experiment, IDEM achieves better results in comparison with state-of-the-art methods, and is the most stable method.

Fig. 1. Partial face images of the same subject taken from the Extended Yale B database.

Table 1. The average recognition rates(percent) and std of different methods

Methods	4	8	12	16	20

IDEM	**96.13±1.39**	**97.78±0.65**	**98.75±0.15**	**98.98±0.056**	**99.32±0.059**

Conclusions

We propose a novel image feature representation method coined IDEM and apply it to face recognition. Given a face image, we first captures the orientation information by implementing arctangent operator for each pixel. Then, by executing Euler mapping, each orientation image is decomposed into two mapping images. Finally, each mapping image is normalized using the "z-score" method and we concatenate all normalized vectors into an augmented vector. The dimensionality of the augmented vector is further reduced by LDA to yield a low-dimensional feature vector. Our experimental results show that IDEM achieves better results.

Keywords: HSV color space, RGB color space, quantized color code

Abstract. The visual attributes of color are suitable for human perception and computer vision. A Color space is defined as a model for representing the intensity value of color. We propose a color space comparison and analysis between RGB and HSV based images retrieval. We succeed in transferring the image retrieval problem to sequences comparison and subsequently using the color sequences comparison between the color featurs of RGB and HSV to compare and analyze the images of database.

Introduction

As rapid growth of internet, digital acquisition of images prevails over the world, the traditional text-based retrievals based on keywords are not sufficient to resolve image retrieval. Content-based image retrieval (CBIR) is a technique used for retrieving similar images from an image database. The query image which based on user orientation to search the most similar images from database. The CBIR system retrieve relevant images from images database by the means of derived features to enhance the accuracy and efficiency of image retrieving. In this paper we describe both color space based method to retrieve images from database [1, 2, 3]. The features of Content-based image such as color, shape, texture and outline are used for image retrieval. Among these features, color is an important feature in CBIR, which is invariant on size, orientation and relatively robust to background complication. A color space is a multidimensional space in which the different dimensions represent the different components of color [7, 8, 9, 10]. The generic model which in terms of mathematical value to describe the representation of color space consist of RGB, CYMK, YCbCr, HSV and so on. In this paper, we proposed the features extraction techniques comparison and analysis between HSV and RGB color space to solve the images retrieval.

RGB Color Space

RGB color space is defined by the three chromaticities of the red, green, and blue primary colors, and can produce any chromaticity that is the triangle defined by those colors, serve as local descriptors of color and texture. Since RGB color space is a 3-dimensional vector space, and each pixel, *p(i)*, is defined by an ordered triple of red, green, and blue coordinates, *(r(i), g(i), b(i))*, which represent the intensities of red, green, and blue light color respectively [6]. We realize that the values of r, g and b are totally different with the altered illumination conditions shown as Fig. 1. However, the relative values between *r(i), g(i)*, and *b(i)* are very similar . Moreover, the number of the permutations of R, G, and B is only 6 (RGB, RBG, GRB, GBR, BRG, and BGR). We append white color series and black color series to let them become 8 series. We utilize 8 rules to transfer each cartoon image to a color sequence as below:

1. If a pixel 235 <= r(i) <= 255, 235 <= g(i) < =255 and 235 < =b(i) <= 255,
then assigns the pixel as 'W';

2. If a pixel 0 <= r (i) < =20, 0 <= g (i) < =20, and 0 <= b (i) < =20,
then assigns the pixel as 'K';
3. If a pixel r (i) > g (i) >= b (i), then assigns the pixel as 'R';
4. If a pixel r (i) >= b (i)> g (i), then assigns the pixel as 'S';
5. If a pixel g (i) > r (i) >= b (i), then assigns the pixel as 'G';
6. If a pixel g (i) >= b (i) > r (i), then assigns the pixel as 'H';
7. If a pixel b (i) > r (i) >= g (i) , then assigns the pixel as 'B';
8. If a pixel b (i) >= g (i) > r (i), then assigns the pixel as 'C';

We can obtain the impression of the characters "G" and "H" present two series of green colors. Subsequently, each image will become a 2D sequence array, and then we will convert the 2D sequence array to a 1D sequence as RRRRRRRGGGCCCHCBCCCCC…RRHHHRRWWWWRRR (20 x 20 =400 characters). An instance illustrates how to obtain a 2D color cipher is shown as Fig. 1 (a) An original frame of sport videos (352X 240 pixels); (b) Resized frame of sport videos (20X 20 pixels); (c) Resized the 20 X 20 pixels frame of sport videos to 322 X 322 pixels) to be seen clearly by readers; (d) Transfer the frame of the resized frame of sport videos (20 X 20 pixels) to a 2D color cipher array. From the 1D cipher array, you can see the layout of the sportsman with a gesture of victory. We compare each element of cipher of the query to the same location element in of the frame in the database. Where two ciphers are equal, increases weight value. If the matching weight value is 400(20 X 20 pixels), then the distance is 0, as shown retrieved image (1) in Fig. 2.

HSV Color Space

The HSV color space is fundamentally different from the RGB color space since it separates out the intensity from the color information. In our efficient alternative system, we employ the HSV color space instead of the RGB color space in two reasons. One is the lightness component is independent factor of images and second is the components of hue and saturation are so closely link with the pattern of human visual perception. The HSV model, defines a color space in terms of three constituent components: Hue, the color type range from 0 to 360 relative to the red primary at 0°, passing through the green primary at 120° and the blue primary at 240°, and then back to red at 360°. Saturation, the "vibrancy" of the color: Ranges from 0 to 100%, and occasionally is called the "purity". Value, the brightness of the color: Ranges from 0 to 100%. For the HSV color space, we map the original image into the HSV color space. We propose the scheme to produce 14 non-uniform colors. The proposed scheme contains three phases. First of all we resize all images to reduce the size of images and processing time. Secondly we convert each pixel of resized image to quantized color code. Finally we compare the quantized color code between the query image and database image. The formula that transfers from RGB to HSV is defined as below:

$$H = \cos^{-1} \frac{\frac{1}{2}[(R-G)+(R-B)]}{\sqrt{(R-G)^2+(R-B)(G-B)}} \quad (1)$$

$$S = 1 - \frac{3}{R+G+B}(\min(R,G,B)) \quad (2)$$

$$V = \frac{1}{3}(R+G+B) \quad (3)$$

For each color's scope of images is nonuniform, the three primary colors of R, G and B possess more scope than the other colors, we segment the scope of the hue which the components of HSV color space into six nonuniform classes including three primary color and the scope interposed between two primary colors, each class depending on the value of saturation of the components of HSV color space divides two subclasses along with the color of "white" and "black" according to the value on saturation and value of the components of HSV color space, the total is 14 classes. Each

pixel of the images from query and database assigned the quantized color code. Compare quantized color code between each pixel of three components of HSV color space of the images (20x20 pixels) from query and database, we obtain the weight of the quantized color code has compared. Sort the weight value of similarity feature vector and the retrieval images are presented.

Results and Conclusion

In this paper, a comparison and analysis for Content Based Image Retrieval using color space features between HSV and RGB is proposed.. The performance of an information retrieval system can be measured in terms of its recall and precision. Precision is the fraction of retrieved documents that are relevant. Recall in information retrieval is the fraction of the documents that are relevant to the query that are retrieved correctly. The experimental database contains MLB sports frames and test images from Wang's image data base. The MLB sports frames are taken from TV video programs. The Wang's images database including animals, sceneries, plants and flowers taken from SIMPLIcity paper[5]. The RGB color space illustrates the system is more robust and reliable, not only can handle different size, miscellaneous color saturation, blurred(as shown in Fig. 2), noise conditions, dissimilar illumination circumstances, and partial occlusion, but also consider the layout or spatial relation of the color. As shown in Fig.2 demonstrates retrieval results of the RGB based system are remarkable even in occlusion situations. On the alternative efficient scheme, we employ the HSV color space instead of the RGB color space in two reasons. One is the lightness component is independent factor of images and second is the components of hue and saturation are so closely link with the pattern of human visual perception. The HSV color space which we proposed as shown in Fig. 4, demonstrates that the retrieved results are more precise than RGB color space scheme as shown in Fig.3.

Keywords: Dyadic wavelets transform. Copy-move forgery. Edge handling.

Abstract. This paper proposed a detection algorithm for copy-move in same image based on dyadic wavelet transform. First of all, four sub images could be got through the decomposition of detecting image by dyadic wavelet transform. Secondly, high-frequency and low-frequency sub image were decomposed into blocks without any overlap and two sub image's dyadic wavelet coefficients were regarded as the eigenvalue of the image block. At Last, both the high similarity among the low-frequency sub image blocks and the low similarity among the high-frequency sub image blocks were selected as a distorted image block. A kind of image edge processing methods was used to improve the tampering region at the same time. Through the experiments, it shows that the algorithm got the higher detection rate and lower error rates.

Introduction

With the rapid popularization of digital products and the fast development of the Internet, digital images have become an important part of the Internet and been applied to media and administration areas. But with the appearance and powerful functions of image processing software, even an amateur can forge images easily and the forged images can not be distinguished by eyes. Thus, the identification technology of digital images has become the hot topic.

The image identification technology can be divided three classes: digital signature, digital watermaking and digital image blind forensic. The digital signature and the digital watermaking need preprocessing and they are initiative forensic technologies. The digital image blind forensic can detect whether images have been forged without no preprocessing and it is a passive forensic technology and becoming more and more popular.

Copy-move is the most common forgery way. It copies some regions of the image to other regions to cover up. J. Fridrich has proposed the block idea and designed to detect image copy forgery areas based on image block DCT coefficient algorithm. Hany Farid and A.Popescu has proposed the analysis methods based on main components. Weiqi Luo has proposed a robust forgery detection algorithm and it uses the main transfer vector to remove wrong similar blocks and get tampering regions. Guohui Li has proposed a detection algorithm based on DWT an SVD and this algorithm can lower the dimension of images and fetch singular value in low-frequency wavelet coefficient moments as eigenvalues of every block to ensure copy-move regions.

The representative algorithms which are motioned above have achieved some results when detecting the same image copy-move. But they also have some problems in detection rate and error rate. Some algorithms have no powerful resistance. The detection rate and error rate is mainly determined by the chosen eignevalues. So this paper proposes a detection algorithm based on dyadic wavelet to improve detection rate and reduce error rate. It also improves the detection time efficiency by using no overlap blocks.

Dyadic Wavelet

Dyadic Wavelet Theory. Generally speaking, if something can use Fourier transform in the analysis, it can also use wavelet transform instead. But the wavelet analysis has better localization features in time domain and frequency domain, so it has more advantages when analyzing object details. Continue Wavelet Transform (CWT) is defined as follows:

$$Wf(a,b)=\int_R f(t)\frac{1}{\sqrt{a}}\psi^*(\frac{t-b}{a})dt=<f,\psi_{a,b}> \tag{1}$$

The parameters a and b in (1) need discretization and $a=2^j$, $b_{j,k}=2^jk$, among them, $j,k\in Z$, the equation of Discrete Wavelet Transform (DWT) corresponding to the arbitrary function $f(t)\in L^2(R)$ is shown as follows:

$$Wf(j,k)=\int_R f(t)\frac{1}{\sqrt{2^j}}\psi^*(\frac{t}{2^j}-k)dt=<f,\psi_{j,k}> \tag{2}$$

There is the fast algorithm Mallat which is corresponding to DWT, but here we don't talk about it in detail. During the fast realization process of DWT, many singular points which are on the edge of images can be gone when sampling. There will be the Gibbs phenomenon during the images reconstruction. It looks like the distortion of image edges. During the process of discrete continuous wavelet transform, if there is the character of translation invariance when transforming, the problems which are mentioned above can be solved. That is DWT.

In the wavelet transform of (1), a=2j, $j\in Z$, b is still the continuous changing values, just like it is in the wavelet transform. About the arbitrary function $f(t)\in L^2(R)$, dyadic wavelet transform can be defined as follows:

$$Wf(2^j,b)=\int_R f(t)\frac{1}{\sqrt{2^j}}\psi^*\left(\frac{t-b}{2^j}\right)dt=<f(t),\psi_{2^j,b}(t)> \tag{3}$$

In that equation, $\psi_{2^j,b}(t)=\psi_{2^j}(t-b)=\frac{1}{\sqrt{2^j}}\psi\left(\frac{t-b}{2^j}\right)$

Essentially, dyadic wavelet can be regarded as the transformation between continuous and discrete wavelets. CWT makes the dimension parameter a and the translation parameter b continuous. Conversely, DWT needs to discretize the two parameters. But the dyadic wavelet transform just discretizes the dimension parameter and the translation parameter in time domain is still continuous. That is the main distinction with DWT. The corresponding fast algorithm of dyadic wavelet transform is the atrous algorithm.

Application of Dyadic Wavelet in This Algorithm. Supposing I is the image which need detection, h[k] and g[k] are low-pass filter and high-pass filter. When j=0, making $I^0=I$, when j=1, 2, J, the corresponding coefficient calculation methods can be get by the equations as follows:

$$c^{j+1}[n]=\sum_k h[k]c^j[n+2^jk] \tag{4}$$

$$d^{j+1}[n]=\sum_k g[k]c^j[n+2^jk] \tag{5}$$

The filter $h^j[k]$ and $g^j[k]$ is determined after every sample is inserted into 2^j-1 pieces of 0 by the filter h[k] and g[k]. The dyadic wavelet transform filtering is described as follows: when j=0, we make $I^0=I$. when getting the dimension function coefficient and wavelet function coefficient of I^J and D^J, we can use $h^{j-1}[k]$ and $g^{j-1}[k]$ to filter I^{j-1}. The corresponding tow-dimension dyadic wavelet decomposition is shown in Fig. 1.

After the dyadic wavelet first level decomposition, the image will obtain four sub images: LL, LH, HL, HH. They are the same side as the original image. The sub image LL is the approaching image of the original image, and HH contains amounts of high-frequency information. The algorithm will choose these two images for analysis.

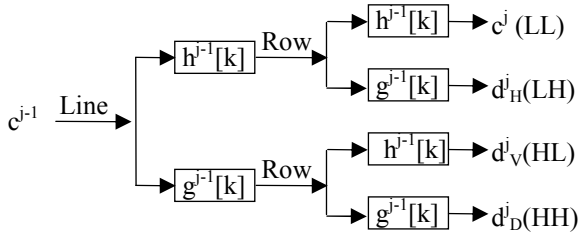

Fig. 1 Two-dimension dyadic wavelet first level decomposition

Detection Alglrithm

Image Block. After dyadic wavelet first level decomposition of the image, we choose LL and HH to do image segmentation. Because the general tampering regions are not very small, it is not necessary to move a pixel. The algorithm in this paper will not divide the image into blocks by movements. It will divide the image into R×R image blocks directly which are adjacent. M×N image is the same as that. After segmentations, there will be $\lceil M/R \rceil \times \lceil N/R \rceil$ pieces of image blocks. Meanwhile, we hypothesis first: copy-move forgery regions are connected instead of very tiny fragment image blocks or even pixel points. The size is at least four times of image blocks. Here, choosing image blocks which are 16×16 size to do the whole image fragmentation can make some image blocks contains a part of image forgery regions entirely.

Similar Region Matching. In LL and HH, we suppose that the size of every image block is R×R and they are all transformed into the matrix form: $1\times R^2$. That is, every image block is transformed into one line. Every image block is act as a vector, all image blocks of LL and HH are transformed into a matrix. The equation of defining the distance between vectors is shown as follows:

$$d(p,q)=\sqrt{\frac{1}{N}\sum_{i=1}^{n}(p_i-q_i)^2} \tag{6}$$

In the above equation, N is 256. It means standardizing the distance between vectors. The corresponding distance value is converted between 0 and 1 to make the setting of threshold value easy. Before dictionary ranking, we define two threshold values Th1 and Th2. Because LL is the approaching image of the original image, we save all the image blocks which d<Th1 in Llist according to dictionary ranking algorithm. The main information in HH is the noise, edge and other high-frequency information of image blocks. As soon as the image is forged, this sensitive information must change and all image blocks whose distance d>Th2 in HH will be saved in Hlist. It will choose image similar blocks pairs in saved image block pairs. The image similar block pairs which are chosen from K_{LL} and K_{HH} are listed Llist and Hlist. If image block pairs appear in the two lists at the same time, that image block will be similar image blocks.

Confirmation of Tampering Regions. After finding out similar image blocks through similar region matching, some image blocks which only contain a part of tampering regions and can not be enough similar may not be detected. That is because it is not the overlapping image segmentation. The detected image blocks almost contain tampering regions. Thus, confirmation of tampering regions is necessary. There is an edge handling method of image blocks and it is shown in Fig. 2.

In Fig. 2, a grid represents an image block. Assuming the part comprised of X and Y is the similar image which has obtained just before. It is also the region which X edge contains. The specific steps are as follows:

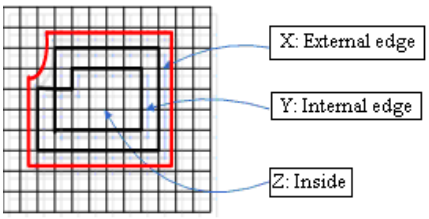

Fig. 2 Edge handling of tampering regions

(1) Conformation of inner edges of image blocks. To the former similar image blocks, every detected similar image blocks will be judged in four domains (up, down, left, right) image blocks. If all the four domains are in distorted image blocks, it will be grouped in Z (inside) in the Fig. 2. If one to three domains are image blocks, then they will be grouped in Y (internal edge). Nonexistent image blocks will do nothing.

(2) Conformation of external edges. All the eight domains image blocks in Y image blocks will be marked. The image blocks which are already in Y and Z will do noting. The rest are grouped in X (external edge).

(3) Improvement of tampering regions. The former internal edge image blocks are overlapping according to the movement of pixel whose step side is 1. The biased direction is from Y to X and they are all in X. Eventually, the tampering regions are confirmed.

Algorithm Flow. (1) Supposing the size of detecting image I as M×N, we transform it into 256 level grey spaces;

(2) After dyadic wavelet first level composition of images, we can get sub image LL and HH;

(3) LL and HH will do the non-superimposed image block. The size of every image block is 16×16 and they are adjacent;

(4) To LL and HH, every image block eigenvalue of every sub image will be in line to establish feature vector matrix and constitute the K-D tree KLL and KHH of LL as well as HH;

(5) Set threshold value Th1 and Th2. KLL tree will be saved in Llist by searching every image block pair that the node distance is less than Th1. KHH tree will be saved in Hlist by searching every image block pair that the node distance is more than Th2;

(6) Choosing the image block pairs which are in both Llist and Hlist as distorted image blocks;

(7) Do the image edge handling and improve tampering regions;

(8) The algorithm ends.

Experiment Results and Analysis

The environmental parameters of this experiment are: Pentium (R) Dual-Core CPU T4200 @ 2.00GHz, 2.00GB memory, the OS is Windows XP and the formulation platform is Matlab R2009b.

In the experiment processing, the equations of defining detection rate r and error rate w is as follows:

$$r = \frac{\sum_i |A_i \cap P_i| + |B_i \cap Q_i|}{\sum_i |A_i| + |B_i|} \tag{7}$$

$$w = \frac{\sum_i |A_i \cup P_i| + |B_i \cup P_i|}{\sum_i |A_i| + |B_i|} - r \tag{8}$$

In equation (7) and (8), A_i and B_i are copy-move regions of detecting images. P_i and Q_i are detected regions.

The experiment uses grey images. If the images are colorful, it will transform color images into grey images firstly and then begin handling. The image size of the experiment is 320×320. The original image is copy-move forged by Adobe Photoshop CS. the parameters in the experiment are: the size R of image block is 16, the domain value Th1 is 0.72 and Th2 is 0.29.

An original image is shown in Fig. 3. The image after copy-move forging by photo editor is shown in Fig. 4. The result which is detected by our algorithm is shown in Fig. 5. We can see that the two white regions are the copy-move regions.

To compare the algorithm in this paper with the DCT coefficient algorithm based on image blocks, we have performed an experiment as follows. We have used 500 pieces of 320×320 images and forged them and then use the above algorithms to do forge detections. The statistical data are shown in Table 1.

From Table 1, the algorithm in this paper has improved detection rate and reduced error rate. Thereason is the comprehensive analysis of sub images LL and HH after dyadic wavelet decompositions

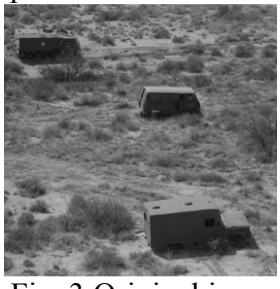

Fig. 3 Original image

Fig.4 Distorted image

Fig.5 Detected result

Table 1.Comparison of Detected Results

	Algorithm in this paper	DCT coefficient algorithm
Detection rate	93.0%	91.6%
Error rate	5.2%	9.4%

Conclusions

This paper proposed a detection algorithm for copy-move based on dyadic wavelet transform. This algorithm has image blocks without any overlap and analyses low-frequency and high-frequency sub images after dyadic wavelet decompositions. It has improved the detection rate and reduced the error rate. But this algorithm also has some disadvantages. For example, it can no resist the handling ways of rotations, zooms and so on. Those are the further investigative orientations.

Keywords: LTE; HARQ; PUSCH; PUCCH

Abstract. A brief introduction of hybrid automatic repeat request (HARQ) is given first, and then a description of physical uplink shared channel (PUCCH) or physical uplink shared channel (PUSCH) receiving and reporting the HARQ-ACK information in bundling mode or multiplexing mode is made in detail. Based on the principle, a scheme is designed to solve the problem of receiving and reporting the HARQ-ACK information.

Introduction

HARQ (hybrid automatic repeat request), which is forward error correction (FEC) applied in automatic repeat-request (ARQ) system .while the FEC can be used to correct the data error in transmission process, that is if the error is in the error correction range of FEC, then the FEC can correct it, if the error is beyond that scope, then the retransmission from the receiver will be made .In the receiver module, the CRC check is usually used to detect the error of the received data packet. If there is no fault, a positive acknowledgment (ACK) will be sent, otherwise, the data packet will be dropped and a negative acknowledgment (NACK) will be sent. The data packet will be retransmitted when the NACK is received. Therefore, the scheme not only increases the reliability of the system but also increases the transmission efficiency of system, it is has been applied to the LTE system.

Feedback of HARQ-ACK Information in bundling mode

The generation of HARQ-ACK feedback information needs the some parameters in bundling mode, while V_{DAI}^{UL} is the value of the downlink assignment index (DAI) in downlink control information (DCI) format 0 detected by UE, V_{DAI}^{DL} is the value of DAI in DCI format1/1A/1B/1D/2/2A/2B, U_{DAI} is the number of physical downlink control channel (PDCCH) released, N_{SPS} is the number of physical downlink shared channel (PDSCH) without PDCCH indicated[1]. For time division duplexing (TDD), when in the HARQ bundling mode or the HARQ multiplexing mode with M equals to 1, while M is the number of downlink subframes that need to report feedback information in an appointed subframe, if the HARQ-ACK feedback information is sent via physical uplink shared channel (PUSCH), the parameters above can be used to detect whether the downlink tasks are lost, the method is as follows [2].

When the uplink and downlink configuration is set to 0, if the PDSCH transmission is detected in the subframe $n-k$, whether there is corresponding PDCCH indicated or not, N_{bundled} is set to 1.When the uplink and downlink configuration is set to 1-6, the HARQ-ACK information is transmitted via PUSCH and the transmission is made according to the detected DCI format 0,if

$V_{DAI}^{UL} \neq (U_{DAI} + N_{SPS} - 1) \bmod 4 + 1$, it means at least one downlink assignment has been lost and then UE will generate NACK for all codewords ,at the same time set $N_{\text{bundled}} = V_{DAI}^{UL} + 2$ [3]. UE shall not transmit HARQ-ACK information when $U_{DAI} + N_{SPS} = 0$ and $V_{DAI}^{UL} = 4$.From the above analysis, it can be seen if the downlink task is lost, NACK will be sent via PUSCH and $N_{\text{bundled}}$is also determined, otherwise, the M downlink subframes' feedback information of each codewode will do the operation of Logic and, one or two HARQ-ACK bits will be generated. When the HARQ feedback information is sent via PUCCH [4], the difference is that the value of N_{bundled} is not needed. In the realization of the process, if the PUSCH transmission is scheduled in the uplink HARQ process, it can be considered that that the HARQ information sent via PUCCH is placed by PUSCH, besides, an array is defined to record the process ID in the process, when in bundling mode, the uplink and downlink configuration 5 should be considered specially, as the uplink and downlink configuration 5 support bundling mode only and all the downlink subframes should be considered in this configuration, then corresponding process ID can be read from the array and the final feedback information is generated ,at last, the right channel is selected to send the final information. The PUCCH or PUSCH receiving and reporting the HARQ-ACK information in bundling mode process can be seen in Fig1.

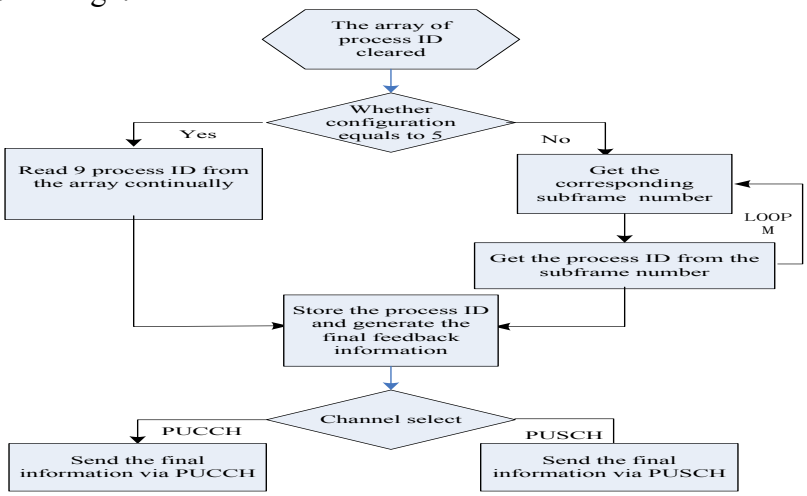

Fig1 Ttion in HARQ multiplexing

When the HARQ-ACK feedback information is sent via PUSCH, for the case M>1 in HARQ multiplexing mode, independent ACK/NACK information of different codeword do the operation of logic and, then UE will determine the feedback ACK/NACK bits when the information is sent via PUSCH[5].

If the transmission through PUSCH is adjusted according to the DCI 0 of PDCCH, unless it satisfies $V_{DAI}^{UL} = 4$ and $U_{DAI} + N_{SPS} = 0$, UE will not send the HARQ-ACK information, or $O^{ACK} = V_{DAI}^{UL}$. While $o_{DAI(k)-1}^{ACK}$ means the PDCCH indicated by PDSCH or released by semi-persistent scheduling (SPS) in subframe n-k, DAI (k) is the value of DAI detected in DCI format 1A/1B/1D/1/2/2A/2B, the information placed order is in accordance with Table 1 that whose distance with subframe n is far. When $N_{SPS} > 0$, it means a PDCCH transmission without PDSCH, then the ACK/NACK information can be mapped to $o_{O^{ACK}-1}^{ACK}$, if there is no PDSCH transmission or SPS indicated by PDCCH detected, set this task is set to NACK [6].

Table 1: Downlink association set index K : $\{k_0, k_1, \cdots$ for TDD

UL-DL Configuration	Subframe *n*									
	0	1	2	3	4	5	6	7	8	9
0	-	-	6	-	4	-	-	6	-	4
1	-	-	7, 6	4	-	-	-	7, 6	4	-
2	-	-	8, 7, 4, 6	-	-	-	-	8, 7, 4, 6	-	-
3	-	-	7, 6, 11	6, 5	5, 4	-	-	-	-	-
4	-	-	12, 8, 7, 11	6, 5, 4, 7	-	-	-	-	-	-
5	-	-	13, 12, 9, 8, 7, 5, 4, 11, 6	-	-	-	-	-	-	-
6	-	-	7	7	5	-	-	7	7	-

If the transmission of PUSCH is not adjusted according to the DCI 0 of PDCCH, then $O^{ACK} = M$, o_i^{ACK} is the ACK/NACK information corresponding to subframe $n - k_i$ ($k_i \in K$)in Table 1. If there is no PDSCH transmission or SPS indicated by PDCCH detected, the result is NACK. When HARQ-ACK feedback information is sent via physical uplink shared channel (PUCCH) and M=1, it can be done as the operations in bundling mode. When M>1, the final two bits are generated according to the tables in protocol. The PUCCH or PUSCH receiving and reporting the HARQ-ACK information in multiplexing mode can be seen in Fig 2.

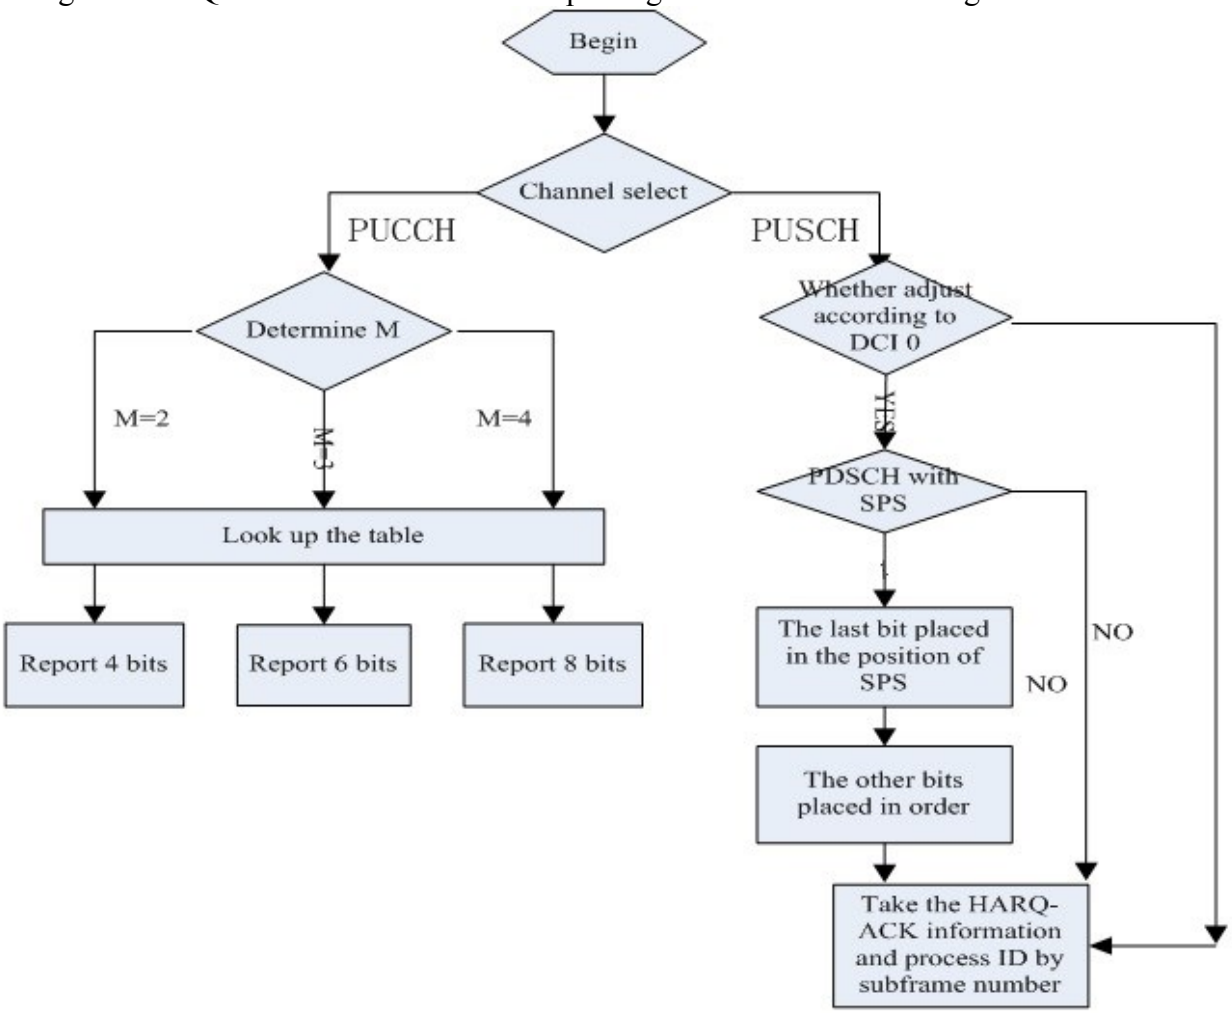

Fig2 The process in in multiplexing mode

Conclusions

This scheme is designed to solve the PUCCH or PUSCH receiving and reporting the HARQ-ACK information in bundling mode or multiplexing mode, when applied in the system through the realization of DSP, the result is reliable; the reliability of the scheme is proved.

Keywords: image enhancement; homomorphic filtering; NSCT; fuzzy enhancement

Abstract. Proposed is an algorithm of NSCT-Based Image Enhancement Combing Homomorphic Filtering With Fuzzy theory to improve the performance of traditional algorithms in the expression of the image edge detail and contrast. With the NSCT, both the low and high frequency sub-band components can be extracted. We dispose of the low frequency sub-band components of the decomposed image by homomorphic filtering and enhance the high-frequency sub-band components with fuzzy sets theory. Then the reconstructed image after above enhancement is obtained by using NSCT inverse transform.

Introduction

Image enhancement is a processing method which to highlight some certain information according to the specific needs and to weaken or eliminate some certain information of an image. Usually, the main purpose of the image enhancement has the following: enlarging the contrast of interest structure of an image and increasing the comprehensibility; reducing or suppressing all the noises mixed in an image in order to enhance the visual effect to some extent[1,2].Generally, image enhancement technology mainly includes two categories: airspace method and frequency method. In recent years, the image enhancement method which is based on wavelet transform, fuzzy set theory, mathematical morphology and multi-scale analysis is wildly used and make a good performance[3-5]. All these methods have achieved a certain performance to some extent.

Image enhancement algorithm

NSCT Transform

NSCT transforming is one of the Multiscale Analysis methods. This method subtitute Nonsubsampled Pyramid Filter Banks and Nonsubsampled Directional Filter Bank for the LP and DFB part of Contourlet transforming[6]. Under the premise of ensuring the original properties of Contourlet, NSCT gets a a fully shift-invariant without downsamplers and upsamplers. Thus, essentially, The NSCT is a fully shift-invariant, multi-scale, and multi-direction expansion that has better directional frequency localizationand a fast implementation[7].

Fig.1 illustrates the struction of NSCT decomposed. At first, the image is decomposed by NFPFB in multiscale, both the lowpass and highpass sub-band can be extracted.And then,NSDFB decomposes the highpass subband into several directional subbands, The scheme is iterated repeatedly on the lowpass subband. At last, we can get the different directional subbands. As a result, it is easier to get the property information of the image using NSCT method.

Fuzzy Enhancement

Pa1.King as a traditional fuzzy edge detection algorithm has some defects. Owing to that transit point got relied on our past experience and several attempts, a large number of gray values in original image are set to 0 rigidly, and the edge information of lower gray values are lost[8]. Therefore, these affect the quality of image enhancement seriously. Based on the shortcomings of traditional algorithms, we use the new membership function as follow:

$$U_{\mathrm{ij}} = \mathrm{T}(g_{ij}) = \log_2\left[1 + \frac{g_{ij}-g_{min}}{g_{max}-g_{ij}}\right] \quad (1)$$

In which, $g_{\min}$ and $g_{\max}$ are the minimum and maximum, respectively. The new membership function values are distributed in [0, 1]. After this treatment, we can save the edge information of lower gray values. We define new non-linear transformation to enhance the blurred image as:

$$\mathrm{U}'_{\mathrm{ij}} = \mathrm{F_r}(\mathrm{U_{ij}}) = \mathrm{F_r}\left(\mathrm{F_{r-1}}(\mathrm{U_{ij}})\right) \quad \mathrm{r} = 1,2,3 \ldots \quad (2)$$

$$F_r(U_{\mathrm{ij}}) = \begin{cases} \frac{\sin\left(\pi(U_{\mathrm{ij}}-0.5)\right)+1}{4} + {U_{\mathrm{ij}}}^2 & 0 \le U_{\mathrm{ij}} \le 0.5 \\ \frac{\sin\left(\pi(U_{\mathrm{ij}}-0.5)\right)+1}{4} - {U_{\mathrm{ij}}}^2 + U_{\mathrm{ij}} & 0.5 < U_{\mathrm{ij}} \le 1 \end{cases} \quad (3)$$

The key of fuzzy enhancement is to increase the membership values higher than 0.5 and decrease the membership values lower than 0.5.Do inverse transform with blurred image and generate the new gray scale. The equation of inverse transform as written:

$$g'_{ij} = g_{min} + (g_{max} - g_{min})\left(2^{U'_{\mathrm{ij}}} - 1\right) \quad (4)$$

From the equation (4), because $2^{U'_{\mathrm{ij}}} - 1 \ge 0$,then $g'_{ij} \ge g_{min}$It also retains the edge detail information of low gray values. Experiments show that the new algorithm is better than the Pa1.King algorithm.

Homomorphism filtering

The classic homomorphism filtering algorithm is compared by establishing lighting reflection model[9],and an image is mainly represented by its incident and reflection components. The equation can be expressed as

$$\mathrm{f}(\mathrm{x},\ \mathrm{y}) = \mathrm{i}(\mathrm{x},\ \mathrm{y}) * \mathrm{r}(\mathrm{x},\ \mathrm{y}) \quad (5)$$

In which, the incident and reflection component is relevance to the low-frequency and high-frequency component in Fourier plane, respectively. However, due to the Fourier transform of the two functions is not separated, so makes the multiplicative components turn into the additive component using logarithmic operation (Formula 6), and then Fourier transform to do it again (Formula 7).

$$\mathrm{z}(\mathrm{x},\ \mathrm{y}) = \ln\left(\mathrm{f}(\mathrm{x},\ \mathrm{y})\right) = \ln\left(\mathrm{i}(\mathrm{x},\ \mathrm{y})\right) + \ln\left(\mathrm{r}(\mathrm{x},\ \mathrm{y})\right) \quad (6)$$

$$\mathrm{Z}(\mathrm{u},\ \mathrm{v}) = \mathrm{I}(\mathrm{u},\ \mathrm{v}) + \mathrm{R}(\mathrm{u},\ \mathrm{v}) \quad (7)$$

Since the transfer function $\mathrm{H}(\mathrm{u},\ \mathrm{v})$ has different effects on the low-frequency and high-frequency components, so selects the appropriate transfer function is critical. In this paper, we use the Butterworth high-pass filter function, it is defined as follows:

$$\mathrm{H}(\mathrm{u},\mathrm{v}) = (r_H + r_L)\left[1 - \exp\left(-c\frac{D^2(u,\mathrm{v})}{D_0^2}\right)\right] + r_L \quad (8)$$

In which $\mathrm{r_H}$and $\mathrm{r_L}$ is defined the high-frequency and low-frequency gain, respectively. $\mathrm{D_0}$ is the cutoff frequency, $\mathrm{D}(\mathrm{u},\mathrm{v})=\sqrt{\mathrm{u}^2+\mathrm{v}^2}$is the distance from point（u, v）to frequency plane origin. The value of Butterworth high-pass filter function dropped the half-maximum when $\mathrm{D}(\mathrm{u},\mathrm{v})=\mathrm{D_0}$. Then it was treated with filtering function:

$$\mathrm{S}(\mathrm{u},\mathrm{v}) = \mathrm{H}(\mathrm{u},\mathrm{v})\mathrm{Z}(\mathrm{u},\mathrm{v}) = \mathrm{H}(\mathrm{u},\mathrm{v})\mathrm{I}(\mathrm{u},\mathrm{v}) + \mathrm{H}(\mathrm{u},\mathrm{v})\mathrm{R}(\mathrm{u},\mathrm{v}) \quad (9)$$

In which, $\mathrm{S}(\mathrm{u},\mathrm{v})$is the Fourier transform after filtered.We can get the enhanced image after the inverse transform.

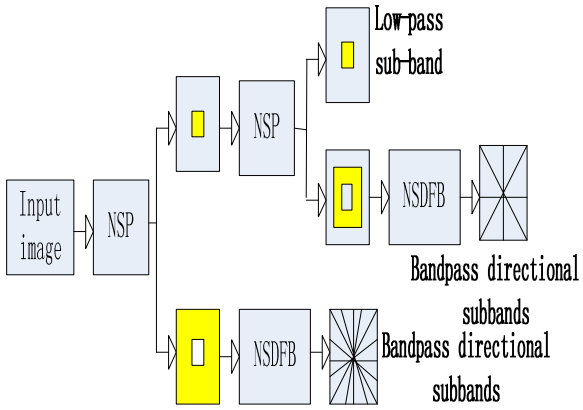

Fig 1. The struction of image decomposed

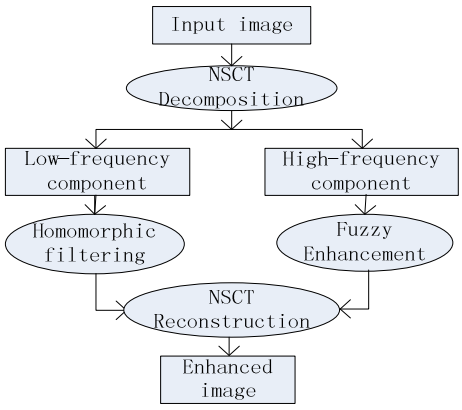

Fig. 2 Flow chart of the proposed algorithm

Steps of the enhancement algorithm

Based on Combing theory and algorithms of 3.1 and 3.2 mentioned, the specific execution steps are as follows and the flow chart of the proposed enhancement algorithm is shown in Fig 2.

(1) Decompose the image by NSCT transform to obtain the the low and high frequency sub-band components.

(2) The high-frequency sub-band components of image were decomposed by fuzzy sets theory According to the formula (1) to the formula (4)

(3) The low frequency sub-band components of image were decomposed image by homomorphic filtering According to the formula (5) to the formula (9)

(4) Reconstruct the image by inverse NSCT, so as to achieve the purpose of the image enhancement.

Experimental results

The experimental results are also compared with three different methods. Fig.2(b)–(d) shows the different enhanced images by the Fuzzy based enhancement method , the homomorphic filtering based on wavelet enhancement method and this peper proposed based enhancement method, respectively. For NSCT, we use three scales of decomposition and 4, 8, 16 directions in the scales from coarser to finer, while for the wavelet we choose the" db4" and six scales of decomposition. Fig.2(b) shows sample of encouraging result enhanced by Fuzzy based enhancement method .It obviously that the edge detailed information of enhanced image is improved while gray contrast is not discernible. Fig.2(c) shows the experimental results in which $r_H = 1.2$, $r_L = 0.5$ and c=2.Both edge detailed information and gray contrast of enhanced image are improved but a little blurred. From Fig. 4(d) it is evident that the proposed algorithms have been strengthened to increase the contrast and brightness by preserving the general shape of the original peppers.jpg image. Moreover the enhanced image is more smooth than the figure (b) and (c), and effectively keep the direction and the edge information of original image. So we can draw conclusion that the proposed algorithm is better in the favorable visual effect of image enhancement

(a) (b) (c) (d)

Fig. 1. (a) Original "peppers" image. (b) Enhanced by the undecimated wavelet transform. (c) Enhanced by the homomorphic filtering based on wavelet .(d) Enhanced by the proposed enhancement algorithm

Table 1 Comparisons of image enhancement results

Methods	Fuzzy Enhancement	Homomorphic filtering	The algorithm proposed
MSE	53.358910	30.322326	31.002238
PSNR	28.523295	51.763686	64.552629

To further evaluate the performance of the different enhancement methods objectively. we use mean square error(MSE) and Peak Signal to Noise Ratio (PSNR) to evaluate the different enhanced images. MSE and PSNR are is expressed in (10) and（11）respectively, and the corresponding values are presented in table.1:

$$\mathrm{MSE} = \frac{1}{mn}\sum_{i=0}^{m-1}\sum_{j=0}^{n-1}||I(i,j) - k(i,j)||^2 \tag{10}$$

$$\mathrm{PSNR} = 10\log_{10}(\frac{\mathrm{MAX}_I^2}{\mathrm{MSE}}) = 20\log_{10}(\frac{\mathrm{MAX}_I}{\sqrt{\mathrm{MSE}}}) \tag{11}$$

Where m, n denotes the number of matrix rows and columns, respectively. MAX ,representing the grayscale image, is usually 255.The lower the value of MSE, the larger the value of PSNR, the greater the quality of enhanced images. Table 1 show performance measure values obtained after Applying different enhancement techniques on images. From the table values, it is evident that the proposed method gives higher PSNR compared to other image enhancement value methods. Though the homomorphic filtering based on wavelet enhancement method give Lower MSE values, the visual quality of the resultant image are not comparable with the proposed method.

Conclusion

An algorithm of NSCT-Based Image Enhancement Combing Homomorphic Filtering With Fuzzy theory has been proposed in this paper. Experimental result of comparative analysis concluded the algorithm proposed achieves better enhancement results than traditional image enhancement algorithms. So as to a fast and efficient image enhancement algorithm, how to reduce the complexity of the algorithm and improve the operational efficiency becomes the next focus of the study.

Keywords: Mobile phone library; Radio Frequency Identification(RFID); Book positioning Book Positioning by Radio Frequency Identification Technique in Mobile Phone Libraries

Abstract. Book positioning in mobile phone libraries could make readers acquire books conveniently andquickly. Readers could use mobile phone access to OPAC system, and apply to book positioning systemwhich is based on RFID system for book positioning. The book positioning system combines with the RFIDsystem to fix the position of books, converts spatial information of books to geographic location information,then feedbacks the information to readers by mobile phone.

Introduction

Along with the popularization of mobile phones and their increasingly powerful functions, mobile phone libraries come into being. As long as the Internet is available, readers can enjoy the corresponding services of mobile phone libraries through mobile phones. The shift from desktop terminal to mobile terminal truly realizes readers' dream of "having" a library. Therefore, this paper combines mobile phone libraries with RFID technology so as to realize the book locating function of mobile phone libraries.

Summary of Mobile Phone Libraries' Book Locating System Scheme

As to the book locating through mobile phones, mobile phones firstly access the OPAC (Online Public Access Catalog) system of libraries through the network, and then the OPAC system initiates a book locating request to the book locating system which locates books by combining the RFID system and then converts the spatial information as located to geographical information before feeding back to readers through mobile phones [1].

The book locating through mobile phones should meet the following 3 conditions: (1) Mobile phones have the function of connecting to the Internet and can access a library's OPAC system through the website to search books and initiate a book locating request. (2) Libraries have the RFID-based automated book circulation system. (3) The book locating system can convert the spatial information as located to geographical information and present it in a graphical way to readers.

Basic Components and Operating Principle of the RFID System

The RFID system includes a reader-writer, antennas, electronic tags, and a control terminal.

The reader-writer sends a radio-frequency signal through transmitting antenna. When the passive RFID tag enters into the working area of transmitting antenna, induced current is generated, and then the passive RFID tag sends out the information of its code (carrier signal) through tag. After receiving such carrier signal from the passive RFID tag, the system sends it to the reader-writer which further sends the signal to the backstage main system for processing [2]. as shown in Fig.1.

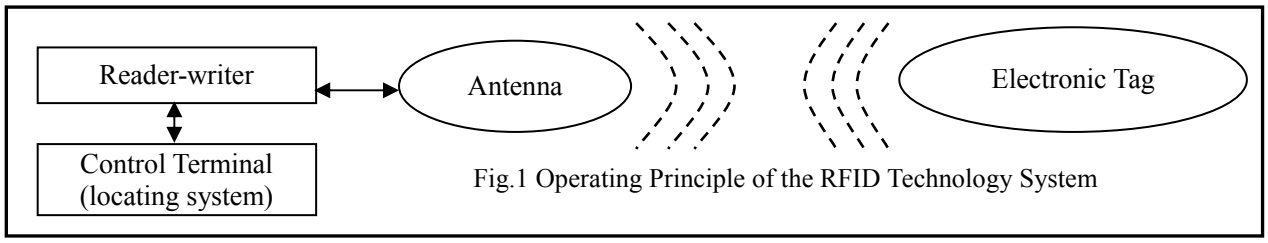

Fig.1 Operating Principle of the RFID Technology System

Realization of Mobile Phone Libraries' Book Locating System Scheme

Proposal of the Location Method of Priority Local Search

The traditional indoor location method is usually based on the TOA (Time of Arrival). Generally it estimates the distance between the tag on books and the reader-writer according to the time of arrival of the signal between the two, thus confirming the location of books. The delay of the transmission time of the signal between reader-writer and book tag will lead to poor location results. Another location method is that the passive RFID tag each book carries will receive the trigger pulse sent by reader-writer antenna to locate books. However, because of the large number of books, these two methods are both time-consuming.

According to the characteristics of library books, this paper puts forward the implementable location method of priority local search. The so-called location method of priority local search means that when locating books, the reader-writer does not search passive RFID tags in sequence, but first conducts local search from a certain location. Since the reader-writer stores the shelf information of any books, it can activate the antenna closest to the book's passive RFID tag as soon as possible to locate the book [3]. This location method of priority local search saves both time and labor and is more feasible than the traditional location method of full-range search.

Implementation Process of the Locating Scheme of Priority Local Search, as shown in Fig.2.

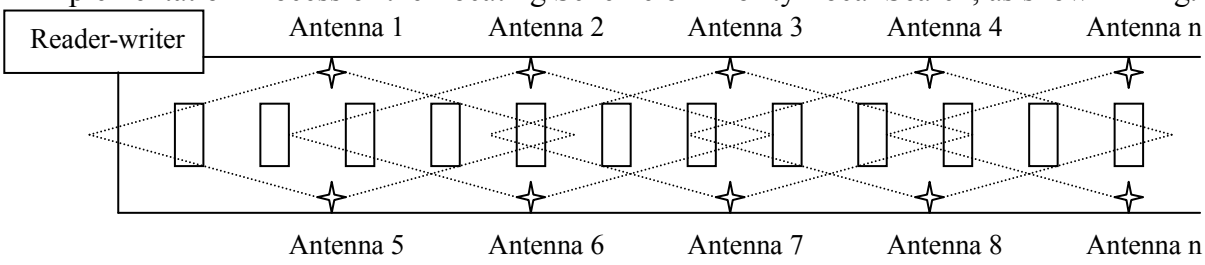

Fig.2 Book Locating System Architecture

In the process of priority local search, the RFID reader-writer in Graph 2 can control multiple antennas that could be activated in sequence. The reader-writer sends the trigger pulse to the first antenna close to it. The built-in antenna of the passive RFID tag tuned to the same frequency "collects" the magnetic field generated by the first antenna. After rectification, the energy received is stored in the capacitor inside the RFID tag. Then the RFID tag immediately sends back the data which is received by the receiving antenna and decoded by the reader-writer.

If no target RFID tag is detected within the read range of the selected antenna, the reader-writer will disconnect the power supply of the selected antenna and then activate each indoor antenna in sequence. If the reader-writer detects the target passive RFID tag, it will record the signal strength it receives and then activate the next antenna to conduct the same detection. If the target tag is detected, it will record the signal strength at the time as well until all antennas are covered. Afterwards, all of the detected signal strengths will be compared and the TOA method will be applied to conduct accurate locating [4].as shown in Fig.3.

The locating system transfers the result of book searching to readers through graphic information so that readers can find the books they need quickly. Since each book shelf is equipped with at least one antenna, the comparison between the coordinate of the target book and the coordinates of the three antennas with the strongest signal can indicate which of the three antennas is closest to the location of the target book. Furthermore, since the bookshelf number of the three antennas is known and the spatial information of the book is also confirmed, the book's bookshelf number can be basically inferred through antenna. Then the general location of the book is further detailed

according to the information of the location and length of the bookshelf, and the finally confirmed location is marked in a graphical way (see Fig.4) and sent back to readers' mobile phones through the website[5] .

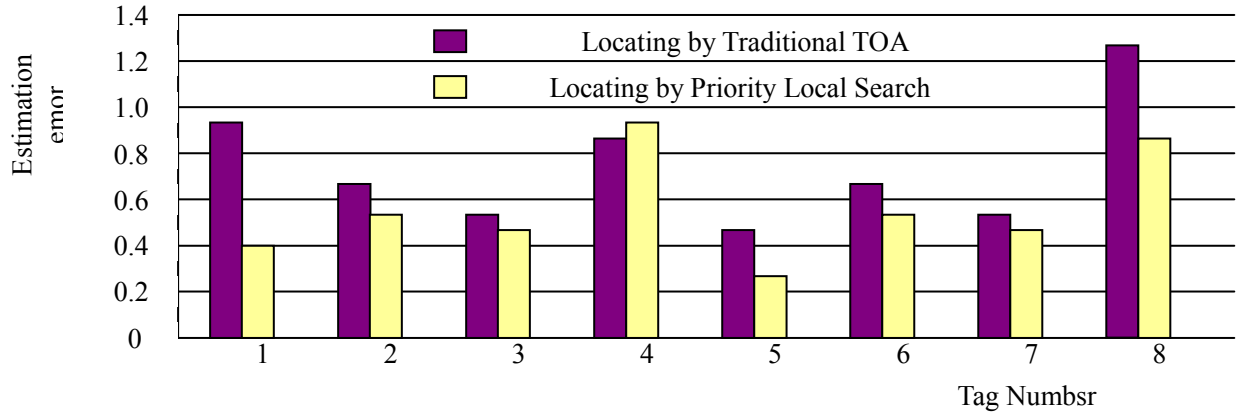

Fig.3 Comparison of Location Error Feed the Locating Information back to Mobile Phones

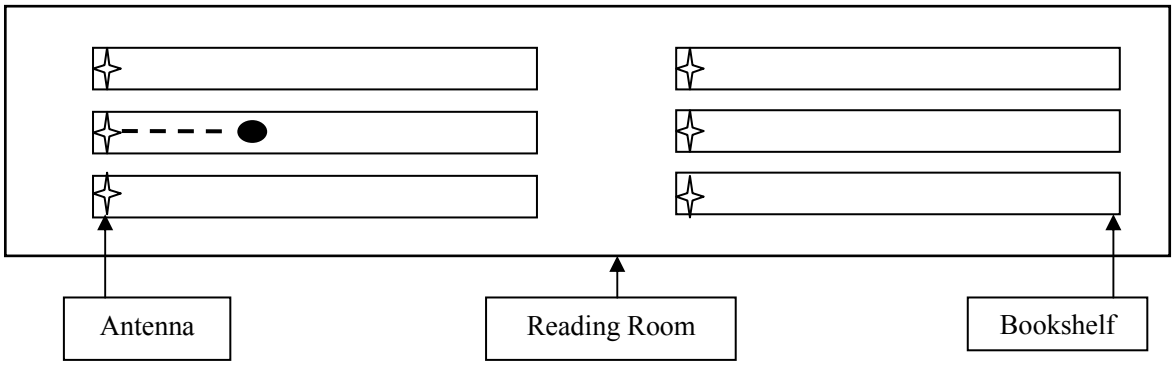

Fig.4 Books' Location Information Obtained by Mobile Phones

Conclusion

In combination with the RFID technology, this paper proposes the location method of priority local search to rapidly locate RFID books. Through the bookshelf information stored in the book locating system and by referring to the historical shelf information of finding the target book, the search scope is narrowed so as to ensure accurate locating. This paper selects the three antennas with the strongest signal to locate books to improve the accuracy.

Keywords: Neural network, Multi-fractal Wavelet model, VBR Video Traffic Prediction, Wavelet reconstruction

Abstract. The video business has gradually become the main business of the network traffic, video traffic is Variable Bit Rate (VBR), which has nonlinear and sudden features, a single prediction model is not fit for describing those features, and prediction accuracy is not high. Because of wavelet analysis has advantages of multi-resolution and dealing with unexpectedness, and the neural network has better nonlinear fitting characteristics, in order to improve the prediction performance, the paper researched on the problem of VBR video traffic prediction based on neural networks, a novel prediction model AMWM is proposed, the model firstly introducing BP neural network to multi-fractal wavelet model, and designing prediction method, which introduced multi-fractal wavelet model to model VBR video traffic, and then applying BP neural network to forecast scale coefficient decomposed, and forecast multiplier using AR model, and predict traffic generated by wavelet reconstruction. Finally, the model is built and simulated. The experimental result shows that prediction performance based AMWM is better compared with multi-fractal wavelet model.

Introduction

With the discovery of VBR video traffic multi-fractal characteristics, people begin to research on VBR video traffic and network traffic modeling using multi-fractal theory. In addition, the wavelet transformation can analyze multi-fractal features of video traffic, therefore, multi-fractal wavelet model (MWM) is proposed in view of current internet increasingly complex network business and video traffic in [1], the model better descript various time scales of wavelet coefficients, but it is a kind statistical model.

As research on prediction model in the previous known, the single model is not suitable for predicting complex VBR video traffic. Therefore, the paper proposed a novel VBR video traffic prediction model AMWM combining with the neural network based on multi-fractal wavelet model, the model may more effectively and really predict VBR video traffic, and improve the prediction performance.

Multi-fractal wavelet model principle

Discrete wavelet transformation may conduct multi-scale analysis on signal $\mathrm{X(t)}$, its expression is as follows [2].

$$\mathrm{X(t)} = \sum_{k} U_{\mathrm{J}_0,k}\phi_{\mathrm{J}_0,k}(t) + \sum_{\mathrm{j}=J_0}^{+\infty}\sum_{k} W_{j,k}\psi_{j,k}(t) \tag{1}$$

Where J_0 is the largest scale, $U_{\mathrm{J}_0}{}'_k$ is the wavelet transformation scale coefficient, $W_{j,k}$ is wavelet coefficients, for Harr wavelet transformation, the scale coefficient and wavelet coefficient can be calculated by equation (2,3), $\phi_{\mathrm{j},k}(t)$ is the mother wavelet function, and it can be expressed as equation (4), $\psi_{j,k}(t)$ is scale function , and it can be expressed as equation (5) [3].

$$U_{j-1,k} = 2^{-\frac{1}{2}}(U_{j,2k} + U_{j,2k+1}) \tag{2}$$

$$W_{j-1,k} = 2^{-\frac{1}{2}}(U_{j,2k} - U_{j,2k+1}) \tag{3}$$

$$\phi_{j,k}(t) = 2^{j/2}\phi(2^j t - k) \tag{4}$$

$$\psi_{j,k}(t) = 2^{j/2}\psi(2^j t - k) \tag{5}$$

Where $\phi(t)$ is defined by equation (6), and $\psi(t)$ is defined by equation (7).

$$\phi(t) = \begin{cases} 1, & \text{when } 0 \leqslant t < 1 \\ 0, & \text{when } t < 0 \text{ or } t \geqslant 1 \end{cases} \tag{6}$$

$$\psi(t) = \begin{cases} 1, & \text{when } 0 \leqslant t < 1/2 \\ -1, & \text{when } 1/2 \leqslant t < 1 \\ 0, & \text{when } t < 0 \text{ or } t \geqslant 1 \end{cases} \tag{7}$$

Therefore, equation (2) addition equation (3) launches (8), namely

$$U_{j+1,2k} = 2^{-\frac{1}{2}}(U_{j,k} + W_{j,k}) \tag{8}$$

Equation (2) reduction equation (3) launches (9), namely

$$U_{j+1,2k+1} = 2^{-\frac{1}{2}}(U_{j,k} - W_{j,k}) \tag{9}$$

it can use a multiplier $A_{j,k}$ to descript the relationship between the wavelet coefficient at the same level and scale coefficient by equation (4) ~ (9), namely

$$W_{j,k} = A_{j,k}U_{j,k} \tag{10}$$

So the multi-fractal wavelet model modeling process can be described as flows: to conduct Haar wavelet transform on video traffic data, firstly getting the biggest scale coefficients $U_{0,0}$, and then turning out various time scales $A_{j,k}$, passing out smallest scale coefficient U_N by equation (8) and equation (9), U_N was the final output results.

Design of Prediction Model AMWM

In this section, a novel VBR video traffic prediction model AMWM is designed, specific steps are as follows:

Step 1: Let scale j is 0, and then computing scale coefficient;

Step 2: Generating a random number between minus one and positive one as a multiplier $A_{j,k}$ ($0 \leq k \leq 2j$), on scale j, and then calculating $W_{j,k}$ by equation (10);

Step 3: Let j= j + 1, calculating $U_{j,k}$ by the equation (8) and equation (9);

Step 4: Repeating from step (2) to step (3) until j = N;

Step 5: Let SUCj=[Uj,k]

Step 6: Introducing SUC_0, SUC_1, …, SUC_N to neural network, getting the scale coefficients SUC'_0, SUC'_1, …, SUC'_N corresponding adjacent sequence scale, that is to predict the next set of corresponding scale coefficients by the scale coefficients of the last set of data. Because of neural network is the teacher learning, it must be trained, in order to speed up the training speed, the paper trained by the parallel method.

Where M is the number of BP neural network training data, N is the smallest scale, namely, to predict the scale coefficient of the first M+1 data by the scale coefficient of the last M data; BP neural network 1 to N can use the same structure, parallel processing the N sets of data at the same time, so generating a new set of scale coefficient of each layer, as well obtaining the scale coefficient prediction output value by means of the trained network.

Step 7:Getting the multiplier by the above step 2 to step 3, then using it for the actual data to initialize the AR model, estimating parameters of AR model, and then according to (11), getting the prediction multiplier;

$$X_t - \phi_1 X_{t-1} - ... - \phi_p X_{t-p} = a_t \tag{11}$$

Step 8: Calculating $W_{j,k}$ on the basis of prediction multiplier, and to conduct wavelet inverse transformation combining with the scale coefficient, generating prediction data, as shown in fig. 1. Predicting the first M data by the the scale coefficient prediction value of last M data and multiplier AM + 1, and so on, the first M+2 data can be predicted, etc.

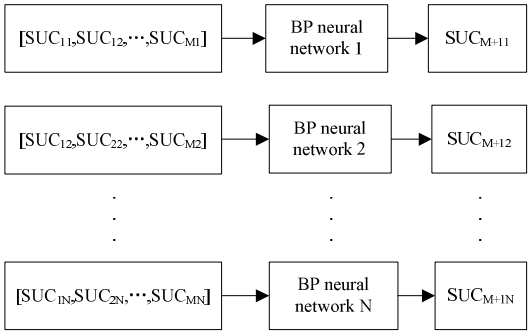

Fig. 1 Predicted data generation method

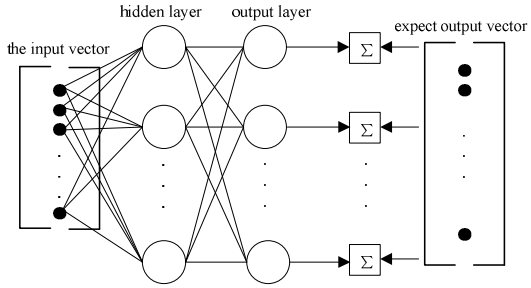

Fig. 2 BP neural network structure

Three layers BP neural network can approximate any nonlinear function [4], as shown in fig. 2, the circles represent neurons nodes, number of nodes in each layer references experience value and the experiment value. The transfer function of hidden layer uses the hyperbolic tangent sigmoid transfer function tansig, and the transfer function of output layer uses linear transfer function purelin, weights and threshold learning function use the gradient descent method, network training function use momentum BP algorithm and it conducts correction on weights and threshold of the neural network, error performance function uses normalized mean square error (NMSE) performance function.

Because the scale coefficient of model proposed in the paper are obtained by Haar wavelet decomposition, they can meet the absolute value of Uj,k less than one, that is as the scale coefficient of the Haar wavelet function and wavelet coefficients nature known, so it isn't necessary to preprocess data before they inputting the network.

After training data in neural network, the output of the network function is linear function, the output value is likely to be between -∞ and ∞, the processing method of Uj,k is as follows:

Step 1: Finding the maximum number of less than one between all the scale coefficients, and replacing the Uj,k, of absolute value greater than positive one.

Step 2: Finding the minimum number of greater than one between all the scale coefficients, and replacing the Uj,k of absolute value is greater than minus one.

Experimental Simulation and Performance Analysis

we carry on experiment confirming the references of three layers BP neural network, the results show the number of input layer nodes are ten, hidden layer nodes are six, output node is one; M is ten, N is three, analysis data length is twenty-forth, so the neural network input vector array was 10*3 dimensional, 10*6 dimensional, 10*12 dimensional, learning rate is 0.04.

We conduct on experiment by "the Silence of the lambs" (from the university of Berlin mpeg-4 video tracking database [5]), As known in fig. 3, it may be observed that when the size of a video

frame doesn't change sharply, the difference is small between the predicted values and the real value; When the amount of data change severely, the difference between the predicted values and the real value also increases, but predicted value can reflect the change trend of real data to a certain degree.

Fig. 4 shows the video predict performance of MWM model and AMWM model in the case of single layer VBR encoding, horizontal axis is preliminary step length, and vertical axis is NMSE values. When the prediction step length was small, the performances of the two methods were close, but, with the increase of prediction step length k, AMWM has smaller error and higher prediction precision.

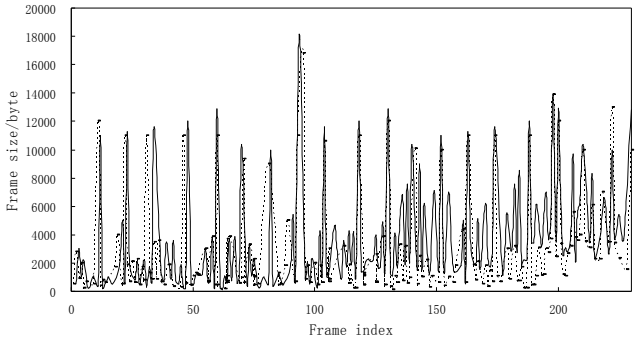

Fig. 3 Simulation results

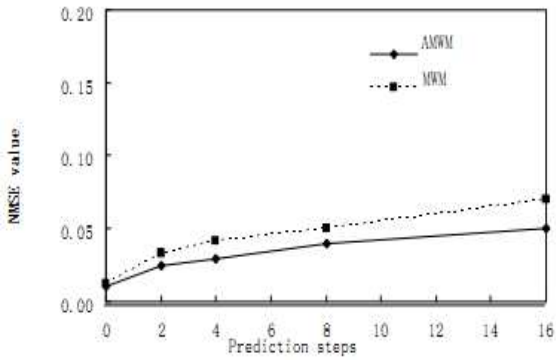

Fig. 4 Prediction performance analysis

Conclusions

The paper studies multi-fractal wavelet model, and then establishes a VBR video traffic prediction model combining wavelet and BP neural network, and the prediction method is designed, and conducted on modeling analysis by Matlab. Fig.3 shows that AMWM prediction model can reflect the change of the original video streams, fig. 4 shows relative to the MWM model, forecasting method proposed in the paper introduces the neural network and can undertake multi-step prediction, and the prediction precision is improved.

Keywords: physical layer network coding ;UAVs; modulation

Abstact. In order to improve the network throughput and anti-jamming capability of UAV communications, physical layer network coding is applied in the UAV communications. Simulation results show that: the use of physical layer network coding can not only improve network throughput greatly, reduce the error rate of communication, but also enhance its anti-jamming capability,which satisfy UAVs' requirements in modern warfare.

Introduction

In some long-distance wireless communication scenarios,the communicating parties do not have the direct path due to mountains and other obstacles blocks.It is necessary to establish a reliable communication link through a high-altitude relay platform. UAVs become the appropriate high-altitude relay platform because of its good performance, low cost, deploying and controlling easily, flexible communications networking and communications equipment[1].

But the UAV as a relay platform needs to meet the following requirements: first, it needs to have a large throughput and high speed to ensure real-time network; second,it needs to have a good anti-jamming capability to ensure the reliability of the network. Most communication system designs try to either reduce or avoid interference (e.g., through receiver design or transmission scheduling [2]). However, instead of treating interference as a nuisance to be avoided, we can actually embrace interference to improve throughput performance.

The scheme of jointing the physical layer network coding with UAV communication meets the above requirements.Compared with the traditional means of communication and the straightforward network coding[3],the network throughput is increased by 100% and 50% respectively,which greatly improves the transmission rate.On the other hand, the interfere becomes part of the algorithm,as a result,it improves its anti-jamming capability.

The design of system model

The communication models of UAVs include communication between the UAVs and the ground, as well as between UAVs and UAVs.

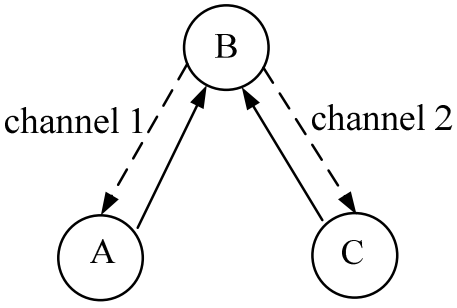

Fig.1. Two-way relay system model

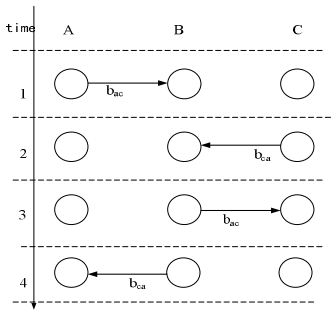

Fig.2. Traditional means of communication

To simplify,following model is extracted which is named the two-way relay system model[4]as shown in figure1:First,two source nodes which are A and C send information to the relay node B separately or simultaneously (this process is called the uplink).Second, the relay node broadcast information to the destination nodes which are node A and C (this process is referred to downlink). Channel between A and B is set to channel 1, channel between B and C is set to channel 2. The relay node deals with the signals differently when the channels are different.

Figure2 shows the traditional means of communication[5]. In the first time slot, the source node A transmits information b_{ac} to the relay node B.In the second time slot, the source node C transmits information b_{ca} to the node B.In the third time slot,the relay node B transmits information b_{ac} to the destination node C.In the fourth time slot,the relay node B transmits information b_{ca} to the destination node A. Node A and node C complete an information-exchange over four time slots.

Figure3 shows the straightforward network coding. Unlike the traditional method,in the third time,the relay node B transmits information $b_{ac} \oplus b_{ca}$ to two destination nodes.It takes three time slots to complete information-exchange.

The main idea of PNC is to create an apparatus similar to that of network coding, but at the physical layer that deals with EM signal reception and modulation. Through a proper modulation-and-demodulation technique at the relay nodes, additions of EM signals can be mapped to $GF(2^n)$ additions of digital bit streams, so that the interference becomes part of the arithmetic operation in network coding[6].

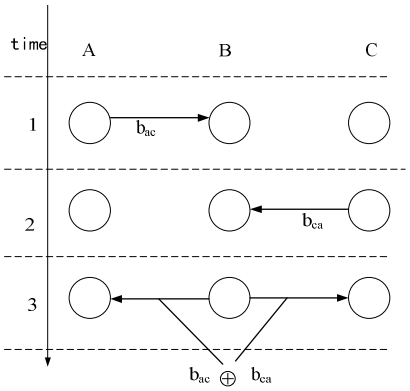

Fig.3. Straightforward network coding

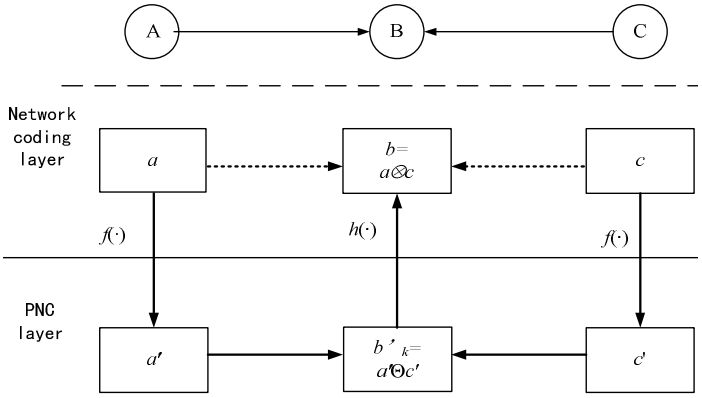

Fig.4.Physical layer network coding flowchart

As shown in Figure3: Let a and c denote the digital symbols, and let $\otimes$ be the general binary operation for network-coding arithmetic (note that $\otimes$ is not necessary the bitwise XOR hereinafter). That is, applying $\otimes$ on a,c.Next,let a' and c' denote the set of modulated symbols in the EM-wave domain. a,c is mapped to a modulated symbol a',c'.Let $f(\cdot)$ denote the modulation mapping function and it is a one-to-one mapping.In the PNC layer,two signals may combine to yield a composite signal at the receiver.Let Θ represent the binary combination operation.That is,combination of a' and c' yield $a' \Theta c' = b'_k$.Note that b'_k is not the same as b and has a higer cardinality than b,and $h(\cdot)$ is a many-to-one demodulation mapping.

In order to research easily, we make the following assumptions:node A and node C exchange information with the help of relay node B.All nodes are half-dulplex,i.e.,a node cannot receive and transmit simultaneously.This is an assumption arising from practical considerations because it is difficult for the wireless nodes to remove the strong interference of its own transmitting signal from the received signal.There is no direct link between node A and node C.The signals transmitted by node A and node B are perfect synchronization,which includes symbol-level time synchronization, carrier-frequency synchronization and carrier-phase synchronization.

Let $s_1(t)$ and $s_3(t)$ denote the signals sent by the node A and node C which have the same phase and amplitude.The received combined signals $r_2(t)$ by the relay node B is

$$\begin{aligned} r_2(t) &= s_1(t) + s_3(t) + w(t) \\ &= a_1\cos(wt) + a_3\cos(wt) + w(t) \\ &= (a_1 + a_3)\cos(wt) + w(t) \end{aligned} \tag{1}$$

In the type(1):The packets of two source nodes are mapped to PNC layer after they are modulated.They reach the relay node after two same channels.$w(t)$ is additive white Gaussian noise (AWGN) with double-sided power spectral density $S_w(f)=N_0/2$. A form is used for a exhaustive description.

TABLE1.PNC mapping

Modulation mapping at node A and node C				Signal processing at B		
Input		Output		Input	Demodulation mapping	Output
s_1	s_3	a_1	a_3	a_1+a_3	r_2	a_2
1	1	1	1	2	0	-1
0	1	-1	1	0	1	1
1	0	1	-1	0	1	1
0	0	-1	-1	-2	0	-1

In the TABLE1,BPSK is used and the noise is ignoring.Next we analyze the bit error rate (BER) performance.

When the noise is added, the relay node in the mapping process need to consider the various threshold values.The maximum a posteriori probability criterion[7]is used to find the decision threshold. The conditional probability density at the relay node is

$$p(\mathrm{r}\,|\,\mathrm{s}_x) = \frac{1}{\sqrt{\pi N_0}}\exp[\frac{-(\mathrm{r}-\mathrm{s}_x)^2}{N_0}] \tag{2}$$

Then find the two decision point

$$r_1 = -1 - \frac{N_0}{4}\ln 2 \tag{3}$$

$$r_2 = 1 + \frac{N_0}{4}\ln 2 \tag{4}$$

Let the received signal be r.When the r is less than r1, declaring a1+a2 to be -2. When the r is more than r2, declaring a1+a2 to be 2.Otherwise, declaring a1+a2 to be 0.Thus, the BER can be derived as follows:

$$\begin{aligned} P_{up} = {} & \frac{1}{2}\int_{-\infty}^{r_1}\frac{1}{\sqrt{\pi N_0}}\exp(\frac{-r^2}{N_0})\,\mathrm{dr} + \frac{1}{2}\int_{r_2}^{\infty}\frac{1}{\sqrt{\pi N_0}}\exp(\frac{-r^2}{N_0})\,\mathrm{dr} \\ & + \frac{1}{4}\int_{r_1}^{r_2}\frac{1}{\sqrt{\pi N_0}}\exp(\frac{-(r+2)^2}{N_0})\,\mathrm{dr} + \frac{1}{4}\int_{r_1}^{r_2}\frac{1}{\sqrt{\pi N_0}}\exp(\frac{-(r-2)^2}{N_0})\,\mathrm{dr} \end{aligned} \tag{5}$$

Above we describe the derivation of uplink.In the following,we will get the derivation of downlink.The relay node broadcast the information processed to node C and node B.

TABLE2.Modulation mapping at B ; Received at C,A

Modulation mapping at B		Received at C		Received at A	
Input	Output	Input	Output （-1 correspondence to same，1 correspondence to same difference）	Input	Output （-1 correspondence to same，1 correspondence to same difference）
r_2	a_2				
0	-1	-1	1	-1	1
1	1	1	0	1	1
1	1	1	1	1	0
0	-1	-1	0	-1	0

In the TABLE2, $r_2 = a_1 \oplus a_3 \in \{0,1\}$ .The signals processed by the relay node B reach the destination node after the channel.Node C and A recover the signals by the information in the cache.

Use the methord as in the uplink,we can get the bit error rate by

$$P_{down} = \frac{1}{2}\int_{-\infty}^{r} \frac{1}{\sqrt{\pi N_0}} \exp(\frac{-(r-1)^2}{N_0})\,\mathrm{dr} + \frac{1}{2}\int_{r}^{\infty} \frac{1}{\sqrt{\pi N_0}} \exp(\frac{-(r+1)^2}{N_0})\,\mathrm{dr}$$
$$= \frac{1}{2}Q(\sqrt{\frac{2}{N_0}}) + \frac{1}{2}Q(\sqrt{\frac{2}{N_0}}) = Q(\sqrt{\frac{2}{N_0}}) \tag{6}$$

Then,we get

$$P_e = \max(P_{up}, P_{down}) \tag{7}$$

Numerical simulation and verification

For details, we make the following simulation graphics.

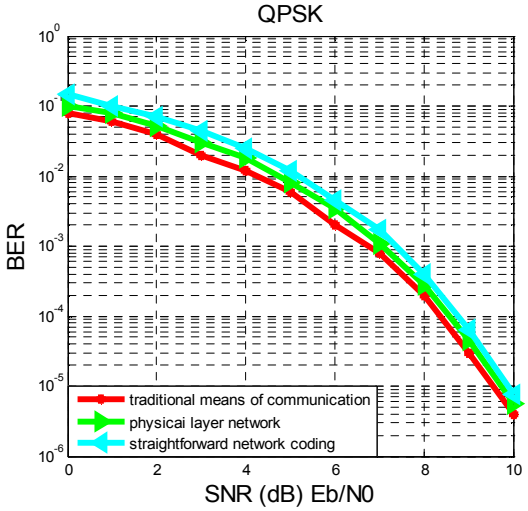

Fig.5. Three different communication methords

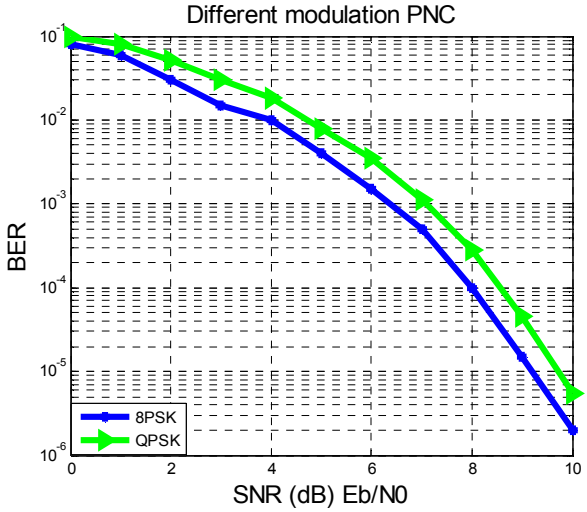

Fig.6. Two different modulation

As the Figure5 shows the BER of the PNC, straightforward network coding,and the traditional means of communition.The BER of PNC is slightly worse than the traditional means of communition,but is slightly better than straightforward network coding.

In the Figure6,we plot the BER of PNC under different modulation.The result shows that the higher the modulation order, the lower the error rate.The reason is that the MPSK modulation increase the euclidean distance.But the higher the modulation order number, the longer relay node data processing.So we must choose the right order number according to the practical situation.

Conclusion

Based on the above numerical analysis,we discover that the use of physical layer network coding in UAV communication systems is an appropriate choice. In terms of network throughput, compared to traditional physical layer network coding communications and direct network coding it increases 1 times and 0.5 times; in terms of the error rate, compared to the direct network coding,the physical layer network coding is lower. Therefore,the UAV communication which uses physical layer network coding will meet the needs of modern warfare.

Keywords: Multi-path; 4G; RAKE; Coherent Demodulation

Abstract. The RAKE receiver has must been used in CDMA or 3G systems for its function to form the diversity reception of signals resulting from multi-path propagations. The basic condition for the implementation of RAKE receiver is that the spectrum spreading (SS) must be used in those systems. But that SS would not be existed in 4G system continuously, and OFDM and QAM would be used in that system instead. So the new method should be found to replace that SS code to separating those multi-path signals, making the RAKE receiver in 4G could be realized. This new method for the implementation of RAKE receiver in 4G System would be introduced in the paper, as well as the performance difference between those two kinds of Rake receiver.

Introduction

There must be multi-path interferences (MPI) existed in any radio channel, which is same for 3G and 4G mobile communication system. Also there is multi-access interferences (MAI) existed in the radio channel of CDMA system. The classical RAKE receiver (CLRAKE) is the basic component of CDMA system. Making use the spectrum spreading (SS) code, which must be included in the CDMA systems, the separation, time-delay adjustment and superposition of signals resulting from multi-path propagations could realized by the RAKE receiver, making the diversity reception being completed. Those signals were considered as MPI in CDMA system, but now the energies of those multi-path signals could be made used. Comparing with the receiver without RAKE, the signal to noise ratio (SNR) of RAKE receiver could be upgraded a lot, as well as the efficiency of the power transmitted. Also the RAKE receiver could be used to restrain the effect caused by MAI in CDMA system, but there is no such MAI similar to that in CDMA system in 4G OFDM system. Upon the important function of RAKE receiver in 3G system there is enough reason to expect that the RAKE receiver should be used in 4G mobile communication systems continuously since the environment of radio wave propagation for 4G is almost the same as that of 3G.

Several block diagrams of RAKE receiver have been given in [1], which are in the configuration of delay reference. Really, RAKE receiver is a kind of diversity reception hidden in time domain, which could be known by the block diagram of RAKE receiver given in [2]. Comparing the configuration in [2] with that in [1], it could be known that the fixed time delay given in the block diagrams in [1] is unsuitable.

One important problem existed in those block diagrams given by the above references is that the input signals of those block diagrams are always a path signal in base-band, meaning that the phase relation among those multi-path signals received by a RAKE receiver has not been considered enough, whose influence has been analyzed in [3][4] specifically, in which a new named as coherent RAKE receiver (CORAKE) is introduced. Now, those RAKE receivers introduced in [1][2] would be named as classical RAKE receiver (CLRAKE) in this paper. Comparing CLRAKE with CORAKE, it could be found easily that the SS code in CLRAKE is substituted by the local coherent carrier in CORAKE. It is well known that the key function of SS code is to separate different path signals from a signal with several path signals. Now, the local coherent carrier in CORAKE could be used for the separation of signals resulting from MPI without SS code such as the OFDM system

[5][6]. Also it would be introduced in the paper how to use the local coherent carrier for the separation of signals resulting from MPI in the OFDM system.

The Principles of Classic RAKE Receiver and Coherent RAKE Receiver

A scheme of CLRAKE receiver for 3-path signals received is shown in Figure 1, and the scheme in [2] is similar with that in Figure 1, in which the third path $PN_{I3L}W_{3L}$ is assumed with the maximum delay.

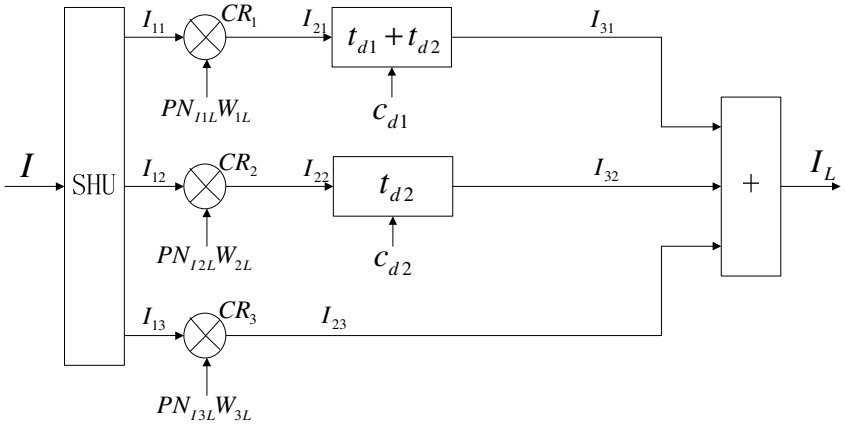

Fig.1. CLRAKE receiver

After the down-conversion in the receiver of CDMA system, the first path signal of some user could be expressed as follows,

$$x_1(t) = D_1(t)W_1(t)PN_{I1}(t)\cos(\omega_1 t + \varphi_{11}) + n(t) \quad (1)$$

In which some user's data is denoted by $D_1(t)$, cell address-code by $PN_{I1}(t)$, the SS code for the uplink channel by $W_1(t)$, the carrier phase of the first path signal received by φ_{11}, and the noise by n(t). The main component of the noise in CDMA is the self-interference formed by MAI and MPI. To simplify the derivation process, only the MPI has been considered.

In Figure 1, $PN_{I1L}W_{1L}$ is the local address-code sequence recovered. Assuming that local coherent carrier $\cos(\omega_{1L}t + \varphi_{11})$ is synchronized to the carrier in the first path signal received. Corresponding to $PN_{I1L}W_{1L}$, the input signal of SHU in Figure 1 is that

$$I = I_1 + I_2\cos\theta_2 + I_3\cos\theta_3 \quad (2)$$

In which I_1 is the output of the coherent demodulating of the first path signal received, θ_2 and θ_3 are the phase differences between the carriers of the second, third path signals received and the carrier of the first path signal received respectively.

The output I_{21} of correlator CR_1 in Figure 1 is that

$$I_{21} = PN_{I1L}W_{1L} \bullet I = D_1(t) + PN_{I1L}W_{1L} \bullet \left[I_2\cos\theta_2 + I_3\cos\theta_3\right] \quad (3)$$

In equation (2, 3), due to the asynchronous between PN_{I1L} and those PN sequences in I_2 and I_3, so these two signals will be treated as self-interference in I_{21}. This noise could be expressed as

$$n(t) = PN_{I1L}W_{1L} \bullet \left[I_2\cos\theta_2 + I_3\cos\theta_3\right] \quad (4)$$

Similarly, assuming PN_{I2L} in Figure 1 is synchronized with $PN_{I1}(t - t_{d1}) = PN_{I2}$ in I_2, there is

$$I_{22} = PN_{I2L}W_{2L} \bullet I = D_1(t - t_{d1})\cos\theta_2 + PN_{I2L}W_{2L} \bullet \left[I_1 + I_3\cos\theta_3\right] \quad (5)$$

In which θ_2 is determined by the delay between those carriers in those two path signals received. While $\cos\theta_2$ is a negative value, the polarity of signal I_{32} is inverted to I_{31}. So it will reduce part of the signal in I_{31}, making the signal amplitude of I_L in Figure 1 be decreased.

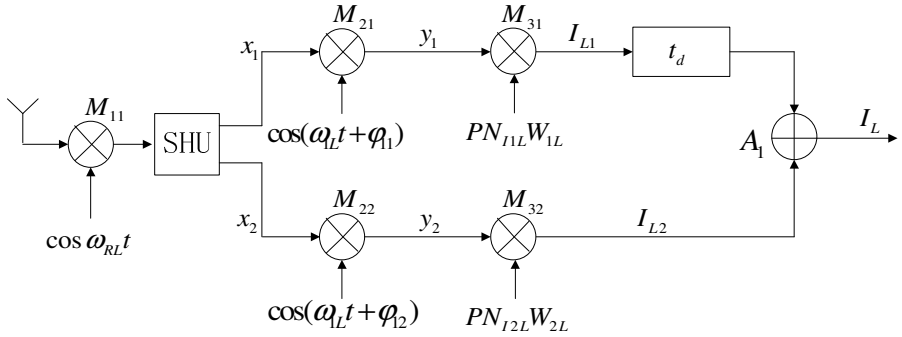

Fig.2. CORAKE demodulator

The scheme of CORAKE receiver for the receiving of two-path signals is shown in Figure 2. Similarly, there are the same assumptions about $\cos(\omega_{1L}t+\varphi_{11})$ and $\cos(\omega_{1L}t+\varphi_{12})$. So there is

$$I_{L1} = PN_{I1L}W_{1L}y_1(t) = D_1(t) + PN_{I1L}W_{1L}\left[I_2\cos\theta_2\right] \tag{6}$$

In which $I_2 = D_1(t-t_d)W_1(t-t_d)PN_{I1}(t-t_d)$, $\theta_2 = \varphi_{11}-\varphi_{12}$, and the last term is the self-interference in CDMA. Similarly, the following could be derived,

$$I_{L2} = PN_{I2L}W_{2L}y_2(t) = D_1(t-t_d) + PN_{I2L}W_{2L}\left[I_1\cos\theta_2\right] \tag{7}$$

In which $I_1 = D_1(t)W_1(t)PN_{I1}(t)$. After signal I_{L1} being delayed by circuit t_d and being summed with I_{L2} in A_1, there is

$$I_L = 2D_1(t-t_d) + n(t) \tag{8}$$

It is clear that the amplitude of I_{L2} would be larger than that of composing output for the corresponding parts in Figure 1.

The Principle Model of OFDM

The principle model of OFDM is given in Figure 3, in which the scheme for modulator of multi-carrier is given really. There S/P means to transform a series of input data stream into several parallel data streams, and that constellation mapping (MAP) means to transform several parallel data streams with two levels in two groups into two amplitude modulation signals with multi-level, and that symbol "+" means a kind of complex adding of those signals of I and Q, which would be used to modulate a pair of quadrature sub-carries denoted by $e^{j\omega_n t}$. That constellation mapping means that some kind of digital modulation such as BPSK, QPSK, 16-QAM or the other similar modulations may be produced. Any OFDM symbol means a QAM or PSK symbol, which is composed of a pair of quadrature sub-carries modulated.

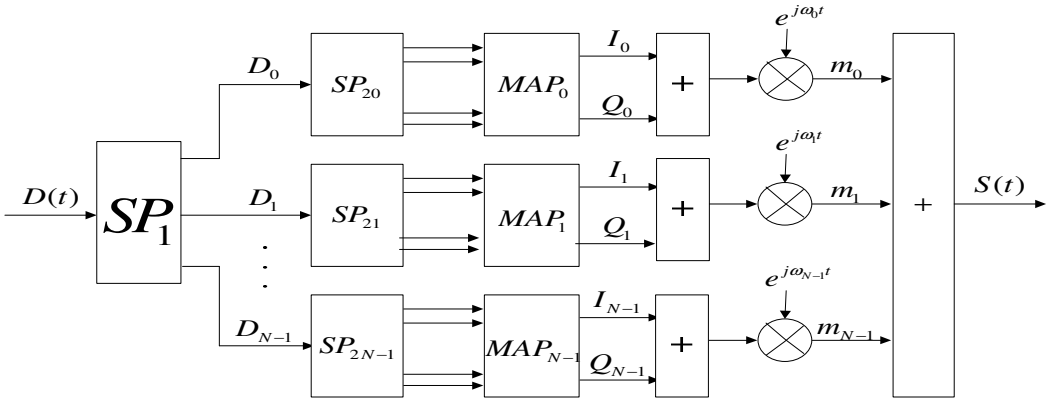

Fig.3. The principle model of OFDM

The expression for MQAM in a symbol could be given as follows,

$$y(t) = I_m\cos\omega_0 t + Q_m\sin\omega_0 t \qquad 0<t<T \tag{9}$$

In which T is used to denote the duration time of a symbol, and I_m or Q_m would with multi-level of amplitude. The number of levels would be decided by that M in MQAM.

The neighboring carrier frequencies in OFDM system must be quadrature which could be defined as follows,

$$\frac{1}{T}\int_0^T \exp(j\omega_m t)\exp(-j\omega_n t)dt = \begin{cases} 1, & m = n \\ 0, & m \neq n \end{cases} \tag{10}$$

It could be known that the receiver scheme of OFDM signal should be similar to that of classic MQAM signal since the feature of quadrature neighboring carrier frequencies, which could be used to save the required bandwidth for the system, would not change the characteristic of MQAM signal, so classic coherent demodulation receiver could be used for the OFDM signal.

The RAKE Receiver for OFDM Signal

The scheme for RAKE receiver of OFDM signal is given in Figure 4, in which $S_r(t)$ is used to denote that received OFDM signal, but it could be processed as an MQAM signal. Since assuming that OFDM signal come from 3-propagation paths, there are 3-path signals included in $S_r(t)$ with different time delay, and only the signal carried by sub-carrier ω_0 is considered. So in Figure 4 there are three MQAM demodulators for those 3-path signals. For example, that $DQAM_0$ is used to denote the MQAM demodulator for the 1st path signal, DEL_0 the time delay needed for the 1st path, and cd_0 the controlling signal for the time delay needed. Here assuming that the 1st path signal has minimum time delay compared with the other path signals. The local coherent carrier $\cos\omega_{01L}t$ is synchronized with that $\cos\omega_0 t$ in the 1st path signal received in phase. Similarly, assuming that 6-path local carriers are synchronized with those corresponding carriers in the multi-path signals received in phase and according to Figure 4, there are

$$I_{01}=I_{r01}+I_{r02}\cos\theta_2+I_{r03}\cos\theta_3+Q_{r02}\sin\theta_2+Q_{r03}\sin\theta_3 \tag{11}$$

$$Q_{01}=Q_{r01}+Q_{r02}\cos\theta_2+Q_{r03}\cos\theta_3-I_{r02}\sin\theta_2-I_{r03}\sin\theta_3 \tag{12}$$

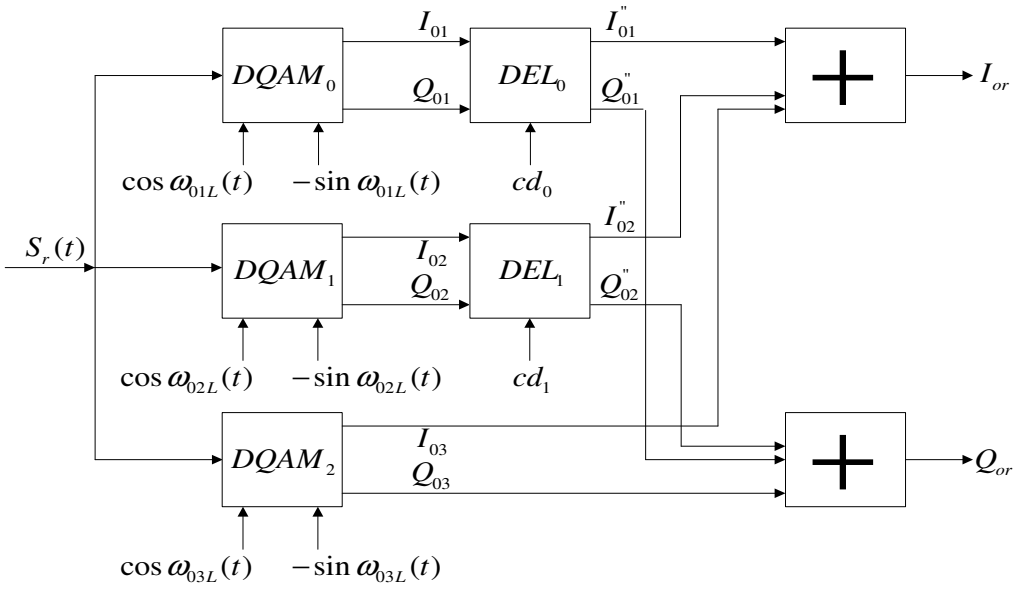

Fig.4. The RAKE receiver for OFDM signal

In which I_{r01} being used to denote the signal received in the 1st path carried by ω_0 is corresponding to I_m in Eq.(9), θ_2 and θ_3 to denote the phase differences between the carrier of 1st path signal and the carriers of 2st path or 3st path signal respectively. Similarly, the equations for $I_{02}, Q_{02}, I_{03}, Q_{03}$ given in Figure 4 also could be deduced. Analyzing the Eq.(11) and Eq.(12) further, it could be found that apart from I_{r01} there are many other terms to be considered as noise

resulting from MPI. Generally speaking, such kind interference should be restrained by some method. According to Eq.(11),

$$I_{0r} = I_{r01}(t - t_{d0} - t_{d1}) + I_{r02}(t - t_{d1}) + I_{r03} \quad (13)$$

In Rayleigh fading conditions, assuming that all amplitudes of 3-paths signals received are the same in Figure 4, the amplitude of I_{0r} would be 3 times of that for a single path receiver. It is easy to derive that the SNR gained by the scheme in Figure 4 is 4.8 dB about.

It has be shown in Figure 4 and by Eq.(11) or Eq.(12) that the separation of 3-path signals received could be realized by the coherent demodulations for different path signals separately, separation and coherent demodulation being realized simultaneously. Also the defect of CLRAKE resulting from the phase difference θ_2 and θ_3 among carries in 3-path signals received could be removed.

Conclusions

Before it is well known that RAKE receiver must be used in CDMA system since that receiver must be constructed on the basis of spectrum spreading communication. But according to the method, presenting by us before in [3], of to separating different path signals confused in a signal received by coherent demodulation, the RAKE receiver could be used in any communication system almost, and significant SNR gain would be obtained. Limiting by the space of this paper, such as how to recovering the local coherent carrier and how to produce the control signal of time delay component have not been discussed in the paper, and they should be studied further.

Keywords: mobile learning; 3G; system design; 4G

Abstract. By analyzing mobile learning application mode of 4G network, combining with the technical characteristics of 4G network , a mobile learning system based on 4G was proposed. We described the architecture of system and found a solution to the flexibility question of multimedia service development in mobile learning.

Introduction

As an effective combination of mobile communication technology with the digital learning ,Mobile Learning is considered to be a future learning mode, or a kind of learning mode indispensable in the future, bringing learners a brand new feeling whenever and wherever learning is possible. Being flexible, convenient, and “random-access", Mobile Learning has become a hot topic in the research of modern educational technology. Learners can learn shortly and quickly at any time, anywhere without being constricted by desktop. In the afternoon of December 4, 2013, the Ministry of Industry and Information Technology officially issued 4G licenses, announcing China’s communication industry entering into the 4G era, which also marking that the mobile learning platform, based on 4G network, will bring a brand-new feeling for teachers to learn whenever and wherever .

3G and 4G

Compared with 3G mobile technology, the fourth generation communication network can connect different fixed and wireless platform across different frequency bands, truly providing consistent and seamless mobile computing environment and supporting high-speed data transferring capacity in high-speed mobile environment, with lower network expense to realize high quality transmission of voice, data and image. In addition, 4G can provide users with personalized service defined by themselves, which precisely meets the requirements of high quality and large data for mobile learning in the modern sense. In order to reflect more directly the significant improvement in performance and service of 4G communication technology, this paper is about to make a comparison between 4G and existing 3G technology in the service, network structure, transmission speed, frequency range, connecting method and module design [1].

Service, 3G focuses on voice, with video-calling, while 4G can realize voice, video-calling, video conference and multimedia communication.

Network architecture, 3G is a WAN mode of base-station tower with high costs, complicated construction, and incomplete coverage. While 4G is a mixed mode of LAN and WAN with low costs and integration with existing network construction. Its network capacity is 5-10 times more than that of 3G, also its transmission quality is better than that of 3G.

Transmission speed, 3G is 2Mbs (actual deployment 384Kbps),and the speed can be even lower where interference is strong. However, 4G is 20-100Mbps; its speed can be as fast as being connected.

Frequency range, 3G is 1.8-2.5GHz, which means that bandwidth and frequency range is too narrow. As all mobile users occupy the same frequency and bandwidth, the "near-far effect" problem is quite serious. However, 4G is 2-8GHz. Its power control is more precise than that of 3G, and mobile and the base station use power control simultaneously and strictly, thus solving the "near-far effect" problem.

Connecting method, 3G is CDMA, based on wireless technology. It needs to adopt expensive and complex adaptive anti-interference device, whereas 4G uses OFDM which is a kind of high speed transmission technology, which can effectively resist signal interference. And the cost is low.

Module design,3G adopts wireless optimization design, lacking enough IP support, wireless transmission technology with a unified format, and a core network. While 4G uses smart antenna which is adaptive to low adjustment direction for tracing signal changes, thus gain signal coverage, system capacity, service quality etc. at a lower cost.

In addition, 4G communication technology has a significant improvement in communication, coverage method and tariff etc..

Communication becomes more flexible, Mobile phone function, based on 4G communication technology, will not only be limited to phone call, message, Internet etc. The phone can also be used for two-way downloading data, image, video, all kinds of entertainment and learning information, which can be compared to a tiny computer.

Seamless coverage. 4G communication system will implement global-unified standards, allowing "seamless connection" among all kinds of media, communication equipment and network. Besides, 4G communication technology allows using wireless network unlimited by time and space.

Low cost. 4G communication not only has a good compatibility with 3G communication for users to upgrade easily, but also introduces many advanced communication technologies to ensure a highly flexible system operation mode. Thus compared with other technologies,4G communication deployment can be far more easy and fast [2]. Also, communication operators would consider directly construct 4G network communication system based on 3G infrastructure step by step, so that it can effectively reduce costs from both operators and users. The cost of instant wireless connection and some other services in 4G communication will be cheaper than 3G communication.

Application mode of mobile learning based on 4G

A. Mobile learning mode based on 4G real-time mobile video service

4G real-time mobile video is one of the core application of 4G service, sending users video content through mobile network and mobile terminal. 4G network is capable of transmitting high quality video image in parallel with HDTV. To some extent, mobile learning based on 4G real-time mobile video service will have a great impact on mobile learning based on 3G [3]. Because with the help of network bandwidth provided by 4G technology, learners can get a higher network transferring bandwidth no matter in indoor, outdoor or in mobile learning. Mobile learners access gateway when wireless network is accessible through mobile terminal, so as to achieve teaching video on demand, live or download, enjoying the fast surfing experience of mobile learning; Providers provides the teaching video content through wireless access mode which has greater flexibility and mobility compared with the mobile learning mode based on 3G and thus realize the real-time interaction between teachers and students whenever and wherever possible.

B. Mobile learning mode based on 4G and cloud computing

The use of expanded 4G network will make the data and application for online storage in cloud computing become more attractive than today. 4G-based cloud services will have a significant improvement in the aspect of reliability, functionality and safety for mobile users. Schools and teachers will use "cloud services" supported by “cloud computing" in education and in construction of information environment of individualized teaching. It also supports teachers' effective teaching and students’ active learning, and provides teaching with resource sharing and unlimited storage space and other convenient conditions. So teaching activities will not be restricted by time, space and region, and will get high quality assurance.

C. Mobile learning mode based on 4G multimedia messages

Message service is the most common function of telephone. Applying this function to mobile learning can not only meet the communication requirement from learners, but also be used in the work arrangement, teaching schedule and notice etc. Under the technical conditions of 3G, message can be used to send multimedia messages with text, sound, image, video, thus transferring learning information and develop mobile learning. By way of message, information can be transmitted at any

time between learners and learners, learners and teachers. Information can be transmitted between learners and the Internet as well. In this mode, learners send messages to the teaching server, the intelligent system then changes the message content into a data request based on analysis of the content, and then through analyzing and processing, automatically replies to learners.

Architecture design

Mobile Learning platform refers to the software system providing learners with mobile learning information and learning service support by the use of wireless communication technology and wireless network technology [4]. The architecture of this platform from low to high order is: the presentation layer, the network layer, the business logic layer and the data layer as shown in figure 1,within which the presentation layer is located on the client-side, the network layer is based on mobile communication network and Internet, and the business logic layer and data layer is located on the server.

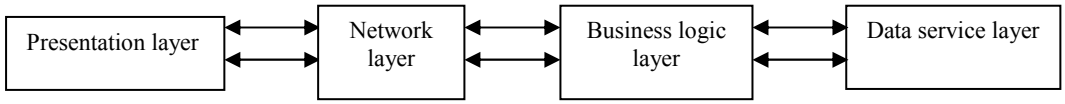

Fig.1. M-learning Platform Based on 4G Network

Based on 4G, Mobile Learning platform uses J2EE (Java 2 Platform Enterprise Edition) database as a permanent data support, integrating large amounts of data for visitors. The system includes mobile phone and some other client-side devices based on J2ME (Java Micro Edition), J2EE server and wireless service provider (China Mobile or Unicom), as shown in figure 2. The require digital education resources are searched through the information channel (4G accessing server) of wireless service provider, and mobile phone client devices access the information on the server. The interaction of the general wireless mobile phone devices and enterprise level application is promoted by the use of underlying data communication technology of wireless field, thus allowing client devices gain access to the server and complete the feedback of data information to the server [5]. This system dynamically separates wireless client and server by using establishment and component technology: sending the information to the server by the wireless client search engine, then processing the return information, and then accessing the corresponding digital educational resources information.

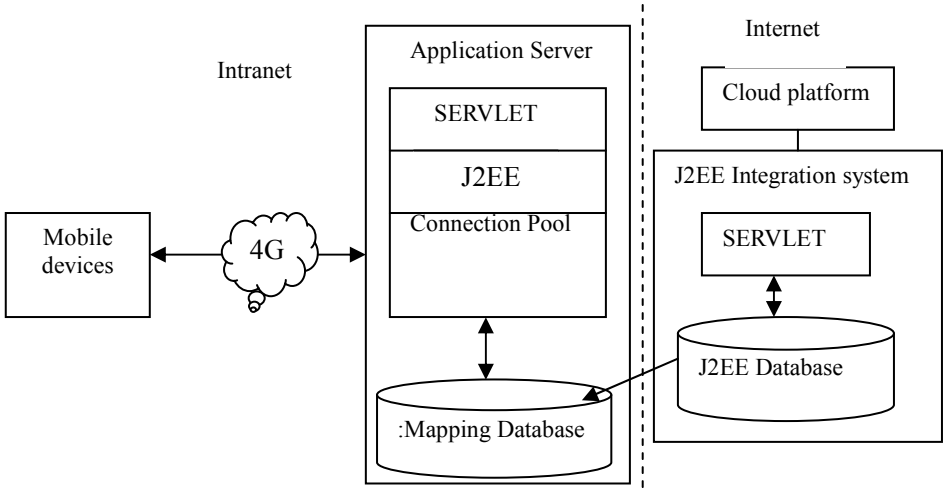

Fig.2. The modules of M-learning Platform

Conclusion

With the development and improvement of 4G network technology and 4G mobile terminal equipment, Mobile Learning helps us realize our dream of lifelong learning whenever and wherever. With the implementation of Mobile Learning platform based on 4G, the complexity of network structure and maintenance cost of operation will be reduced, thus improving the flexibility of multimedia service development in Mobile Learning.

Keywords:3D data acquisition, Body scan, Body measurement, Residual space, Clothing fit

Abstract. This paper presents the method of 3D human body data acquisition based on 3D scanning and the non-contact fit evaluation of clothing based on the distribution features of residual space between clothing and human body. A Kinect camera is employed to collect point cloud data. The points cloud is treated by Geomagic for noise reduction and surface reconstruction. By analyzing the residual space between clothing and human body, the fit distribution of scanned clothing can be achieved. The fit evaluation will make contributions to clothing design, online sales of clothing and virtual try-on.

Introduction

There are two major methods of body measurement in use, one is contact body measurement, and another is non-contact body measurement[1]. The method of contact measurement does not fit for soft materials and ultrathin things for its low measuring speed and inaccuracy.The application of non-contact measurement effectively avoids the disadvantages of low efficiency and poor objectivity.

Non-contact measurement has been widely accepted by companies and scientific research institutions in collecting 3D body data[2], including college of Loughborough, Marks & Spencer, Courtaulds, etc. The common problems exist in 3D scanning includes the cost of device is barely afordable for average customers, and the installation is quite complicate.

As an effort to tackle these problems, we use single Kinect camera to scan body for intact 3D body data[3]. We then process the data through Geomagic software[4] to obtain a triangulated surface model. Different from the work reported by Chen[5], we analyze the dimensional features at key points of human body[6]. We obtain the fit evaluation of clothing through data analysis. The scanning system has the characteristics of simple operation, low cost with fast speed

3D data acquisition

In this investigation, we use Kinect camera (RGB-D sensor) to scan the human body. The RGB-D sensor can obtain RGB color and depth information at the same time. With Kinect fusion algorithm[7], we can effectively decrease the error when measuring body by two-dimensional image and perspective image. RGB-D sensor used in the test can provide serried and accurate gap information, collect 3D point cloud of original clothing, and then it can get high-precision 3D garment prototype.

The test needs to be conducted in an closed environment with stabilized light to decrease noisy points and frame skipping during scanning, as shown in Figure 1. The temperature and relatively humidity are set at 18-25℃, 45%-75% RH respectively according to occupant comfort.

The process of scanning. The common procedure of body scanning follows.

Step1. Identify the position. We regard a fixed standing point as center of a circle whose radius is 1.5 meters, the circle provides a track for Kinect to scan around body.
Step2. Identify scanning point. We set eight equidistant points on the track, when device arrives at each point, we move the camera up and down slowly to obtain high-precision 3D body data.

Step3. Consulting Kinect device with computer. We keep the camera at a settled height, and swing the camera to identify the whole body has been captured. Meanwhile, we observe the point cloud image on the screen for fear of frame skip.
Step4. We keep the body in a settled posture with body standing uprightly, arms stretched and legs separated slightly. We scan the body along the circle, at the starting location we need to move the camera up and down to 'fuse' the points cloud. We move Kinect at constant speed and swing the camera at each point to obtain intact point cloud of human body. The total time to finish one round of scanning is about 2-4 minutes.
Step5. For fit evaluation, we put the clothing (in this paper, we use a shirt as an example) onto the human body, and repeat step4.

Figure 1.Test environment. Figure 2.Original point cloud data. Figure 3.Data after noise reduction.

Data process and fit evaluation of clothing

Data process. We use the Geomagic software to denoise the 3D point cloud data, then we change the surface of point cloud into triangulation structure, the process is called surface encapsulation.

The Geomagic software has the function to finish point cloud data of hook face rapidly, and to generate gridding automatically. In order to shrink the range of point cloud we have measured, we need to wipe them off by using the noise reduction of Geomagic software (Figure 3) to remove the side effects caused by slight shaking of device, bad treated body surface, and inaccurate calibration.

After noise reducing and encapsulation, we have a triangulated model with holes on it (Figure 4).These holes are the data we missed in the scanning process. The little holes can be filled based on the surrounding surface curvature directly. The bigger holes need to be filled from the edge, or the filling will not conform to the actual surface morphology (Figure 5).

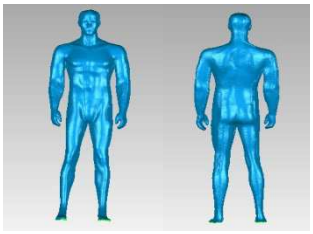

Figure 4.Triangle facet model. Figure 5.The process to fill holes.

To improve the arithmetic speed and enhance operational precision, we reduce the number of surface facet around 20,000 triangles, as shown in Figure 6. Eventually we obtain smooth triangle facet model to analyze the characteristic of the dimension in different parts of body.

Fit evaluation of clothing. Between body and clothing, there are the residual space. This is the foundation of fit/ease evaluation, i.e., we can obtain the fit information by the contact relation between body and clothing, and the size of key points can ascertain major characteristics of body, as shown in Figure 7.

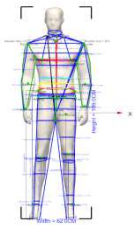

Figure 6.Simplified triangle facet model. Figure 7.Key points of body.

Using the scanned shirt as an example, we calculate the profile distribution characteristics of shirt and body contour along body from bottom to top, as shown in Figure 8.

We segment the dressed and undressed model into many slices horizontally (Figure 9), then we can get fit evaluation through the contact relation between shirt contour and body contour. When shirt contour is smaller than body contour, we think that the shirt doesn't fit for body or the shirt is too tight, on the contrary, when shirt contour is larger than body contour, the shirt fits for body exactly or the shirt is loose.

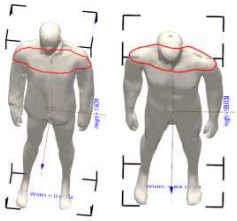

Figure 8.Shirt contour and body contour.

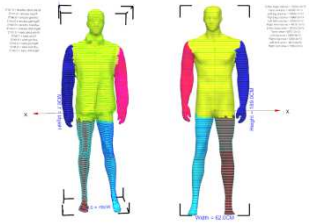

Figure 9.Slices in horizontal.

Therefore, based on the difference of each slice between shirt contour and body contour, we can plot the contact relation between them (Figure 11). Figure 11 shows the data of torso, we have also measured arms and legs (Figure 12, Figure 13). These three figures constitute the complete data of shirt. We can obtain the fit evaluation of clothing from them.

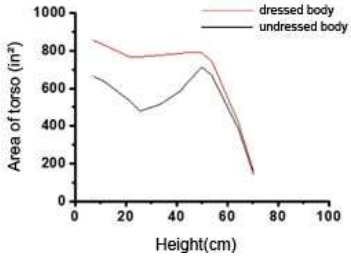

Figure 10.Data of torso.

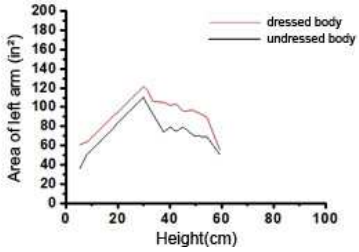

Figure 11.Data of left arm.

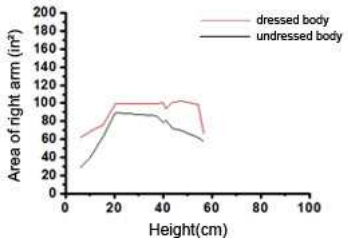

Figure 12.Data of right arm.

We use these curves to evaluate the fit between body and clothing preferably, mixing with subjective feeling to the clothing fits.

The method of getting the contour of body and clothing is shown as follows (Figure 14):

1. Based on the spatial position of the slice I, we can obtain the central location c through weighted average.
2. Set a scanning radius r based on the maximum distance from central location to the edge of the contour, $r = 1.5\max$.
3. Form a circle on the plane of the slice. Make rays from circumference to the center c of the circle, the area between two lines is small enough, we can regard it as a small triangle. We mark the area of the small triangle as S_t, therefore, the area of the whole slice can be calculated by Equation 1.

$$S = \sum_{i=0}^{n} S_t \quad . \tag{1}$$

4. The vector lines intersect the triangles of the slice of body or clothing. Link the points of intersection, we can obtain the contour of the slice.

The advantage of this method is that circular projection points have been ranked, so the sorting of space contour line can be avoided. Meanwhile, accuracy and speed are ensured. In our practice, we divide each contour into 360 points to maintain the accuracy of every slice.

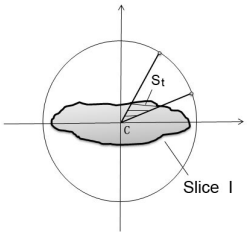

Figure 13.Method of getting the contour.

Result and discussion

The curves mentioned above show the area of the same slice of undressed body and dressed body. We can calculate the difference value of the two areas, then we conclude the minimum and maximum difference value. Mixing with subjective feeling, we can acquire fit evaluation of clothing preferably.

As limited by the test condition, error is inevitable in the original data. This is mainly on account of the low resolution of the RGB-D sensor or heavy noise during the scanning process. Compared with method of two dimensional images, this method breaks the tradition to make it possible to measure virtual models.

Conclusion

In this paper, we introduce a method to collect 3D point cloud data and to obtain fit evaluation of clothing. We calculate the area of slice between body and clothing in limbs and torso area respectively, and conclude the difference value to get fit evaluation method. When subjective feeling is in consideration, the evaluation would be more accurate. The method of collecting 3D point cloud data can also be widely used in fields of clothing online sales, virtual fit, garment customization, medical service and electronic commerce. The fit evaluation will make contributions to clothing design, online sales of clothing and virtual try-on.

Keywords: Post-processing, Telemetry data, Synchronous

Abstract. This paper presents a post-hoc analysis of telemetry data processing systems, introduces the design ideas and composition structure of the system, discussed in detail the design and implementation of key technologies demodulation processing module and the module frame involved. System to achieve a recording deal with post hoc analysis of telemetry data, to solve the current telemetry signal reception playback devices, high maintenance costs, has some economic benefits.

Introduction

At present, domestic and foreign telemetry data recording equipment are high-density tape drive (HDDR) and disk arrays (RAID) two kinds. In recent years, the use of disk arrays to achieve real-time telemetry data recording has become the development trend of satellite ground receiving equipment.[1] The next satellite pass through the high-speed digital data stream collection, storage in the form of data files directly to disk array. With the extensive application of the rapid development of software radio technology and high-performance computers, can adopt high-level computer programming language software system, post-hoc analysis and processing telemetry data.

1 Design ideas

Later analysis of telemetry data processing system through software algorithms programmed manner, the telemetry signal processing applied in the form of digital signal processing program package, to become an independent function modules. In order to meet the needs of different modes telemetry data processing, this system has a modular and reconfigurable features through a combination of a number of functional modules to achieve multi-mode recording after the telemetry signal analysis, processing, display and save.[2]

Telemetry data in accordance with the recording data format, post-hoc analysis of telemetry data processing system reads information recorded on the disk first telemetry data, including telemetry signal and when the system signal. Telemetry signal through the bit synchronization and coherent demodulation, the composition of the telemetry frame has a data structure; through search telemetry frame header, frame synchronization. According to the data structure when the system signals, read B code time records each frame. When the lock header, the B time code added to the header of each frame position to achieve the reorganization of the frame structure. Finally, each frame of the processed data in a format of data stored as files. In the process system, by displaying the window in different display modes to observe the telemetry data frame of each branch. After completion of data processing, data files can be read by processing the waveform data of each branch playback telemetry frame.

Process flow of the entire system is shown below.

In order to improve the operating efficiency of the system, give full play to computer resources, on the basis of the optimization algorithm to simplify logical judgment on the use of multi-threading technology. The whole system includes three threads, one is the main thread, the data processing, set the parameters, control of the whole system running; another two threads for processing data in the background, they are also controlled by the main thread.

To ensure stable system operation, before the data processing system, we must first apply for and initialize memory, ensure that the system memory space effectively throughout the course of the

operation. To prevent memory leaks, each time the system exits normally or abnormal, should release have already requested memory space. Second, the input parameters (example: frame period, the frame code group, etc.), to determine the validity, the input parameters cause the system to prevent unstable operation.

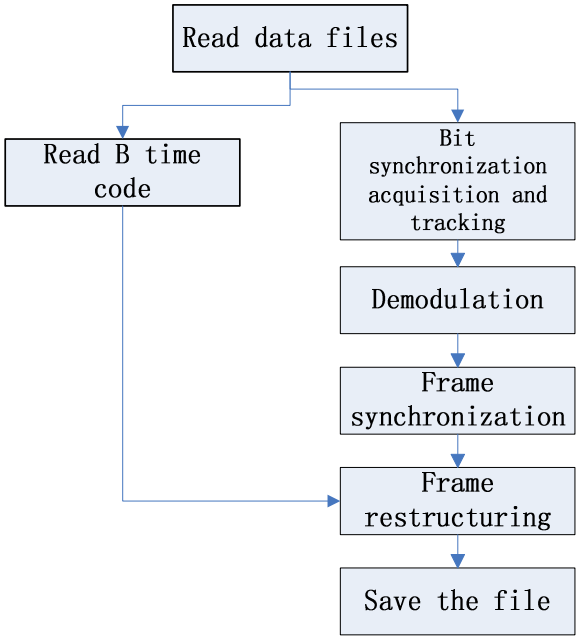

Fig1 System operation flowchart

2 System Architecture

Telemetry data analysis later processing system can be divided into six major functional modules: the main control module, data reading module, timing signal reading module, bit synchronization and demodulation module, frame synchronization module, display and storage module.

The main control module is the main frame system, which controls the running state of the whole system, at the same time, it provides a human-computer interaction interface, realize telemetry data parameter selection and Settings.In order to facilitate the process of observation of the shunt signal telemetry frame in different state, can also through the waveform display window, choose three different display modes.

Data reading module is the input of the whole system, it implements the function is: according to the records of the telemetry data formats, read the telemetry data stored in hard disk and timing signals.For telemetry intermediate frequency sampling signal and pass the cascade extraction about wave, realize the data extraction, reduce the module at a lower level of data processing.

In recording the telemetry signal, in order to reduce the requirement of storage capacity, adopting the structure of parallel branch store, after B code time sampling, in the form of the signal of single bitstream, together with the telemetry data, according to certain data structure stored in the disk.Timing signals read module is on the basis of the data reading module, will read the timing signal, according to the structure of B code decipher the size B time information.

Bit synchronization and demodulation module is the most complex is the most important module in the system.According to the different type of telemetry, first of all, to implement a synchronization.Then, on the basis of the implementation of coherent signal demodulation, and send the results to the frame synchronization module.

Frame synchronization module function is: in the demodulation search frame element in the head and under the conditions of the frame head lock according to the given read shunt data telemetry signal frame structure, and information into the frame head of the time B code, complete the restructuring of the frame structure.

The frame structure of the reorganized in accordance with the certain data types, in the form of files stored on disk.In the process of system processing, according to the user action, can in a variety of display mode at the same time, according to multiple data users select shunt data.

3 Key technology

Intermediate frequency sampling the results of the greatly increased amount of telemetry data record, a lot of redundant data to the system efficiency of pressure.In order to solve this problem, before the telemetry data demodulation, first of all, the high sampling rate after the frequency to baseband signal extraction filter, in meet the Nyquist law under the premise of minimizing baseband signal data, and then after extraction of the baseband signal demodulation.

Due to the input signal of narrow-band digital intermediate frequency processing the sampling rate is very high, but also requires the extraction filter passband bandwidth and transmission belt is very narrow, this will make the filter section number is large, operational efficiency is very low.Therefore, in order to effectively realize the sampling rate conversion, can adopt the method of multistage sampling.Digital cascade extraction filter in general can be divided into three:Comb sampling filter 3~7 times the signal extraction;Half take twice extraction filter signal extraction;Are usually performed low-pass filter compensation filter.

At present, used in the digital frequency measurement algorithm is more, including time domain, frequency domain algorithm time-frequency analysis, algorithm, feature subspace decomposition algorithm, etc.Principle of time domain algorithm is simple, high operation efficiency, therefore, is suitable for the signal of digital frequency measurement.This system USES a time-domain algorithm of instantaneous autocorrelation algorithm for digital frequency measurement.Below is the actual record of a remote sensing signal to digital frequency measurement result, figure dashed range caused by the phase jump in carrier frequency of mutations.We can find that, under the condition of the signal-to-noise ratio of 10 db, via digital frequency measurement method, the location of the change in phase and frequency of sampling data corresponding with the carrier frequency deviation.By judging the frequency transformation range, more quickly to achieve bit synchronization capture and correction.

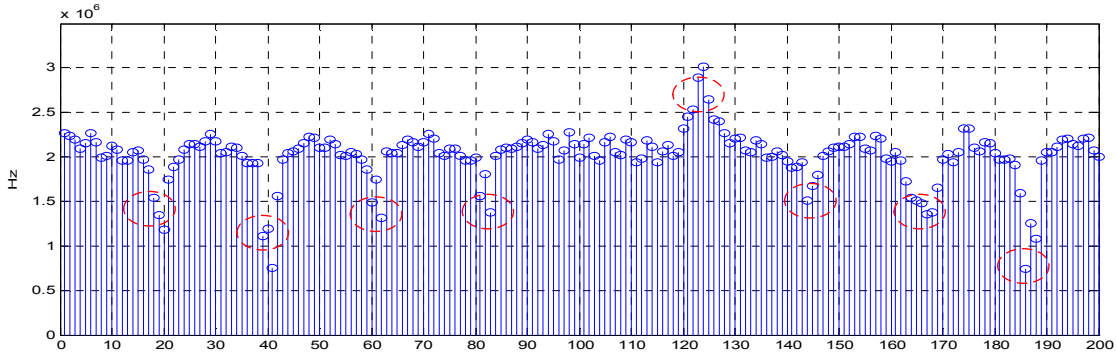

Fig12 Digital frequency measurement results

The telemetry data signal flow to frame as a general identifiable transmission unit, a frame and a frame to transmit sequence.Is placed at the beginning of each frame frame synchronization code (hereinafter referred to as the frame code) as this frame.Select the best correlation between fixed code as a general frame.In order to more accurately identify from the random signal stream frame size, the length of the frame size n (digits) is generally not less than 16.At the same time, in order to facilitate computer processing, the whole frame length of S (hereinafter referred to as the frame length) and the length of the frame size should be set to 8 n integer times.

This system, the frame synchronization locking process is divided into the frame head identification and protection of frame synchronization.Frame code identification of the work process is divided into the following two steps:1, the frame code search: with a known frame code group and demodulation of PCM data are compared, and bit by bit to calculate the number of each phase of ectopic, set by the system fault tolerance for a (i.e., allow with the frame code group has a

different), the system frame head search stage.2, search check: when the first find no fault tolerance after a block of frames, and then to frame by frame, which is in the position to compare the length of the interval of a frame, the system is in search for checking stage.In the process of comparison, once found in the location element is inconsistent with the frame size group, started from the first frame search frame size.If three consecutive frame data are meet the requirements, at this time to get into with gait (i.e., lock the position of the frame head).

Frame synchronization protection work process is divided into two steps: 1, the synchronization protection: system after entering with gait, due to the interference or interrupt may be located in a good frame have appeared over fault-tolerant code position, at this time will need to determine whether really has been out of step, in order to avoid mistakes directly into the search state, the judge also will check after 3 times.If there is no more than 3 times in a row fault-tolerant (set by the system fault tolerance for b), indicating that the frame head positioning is accurate, and can extract each frame of shunting signal, the system is in synchronous protection stage.2, frame head to fish: if in three consecutive frame synchronization protection state is more than fault-tolerant b, frame head position is not correct, the system has entered the stage of out-of-step, and at the same time from the first frame to frame head to search again.

Summary

Telemetry data after the analysis processing system for remote signal analysis and processing provides a new method, solve the current domestic telemetry ground station receives playback telemetry signals of the high cost of equipment operation and maintenance problems, have a certain economic benefits.Because of the characteristic of the software itself is flexible, can achieve a variety of post-processing pattern telemetry signals.Compared with the hardware processing, improve the accuracy of the telemetry data processing, can completely satisfy the DQPDK post-processing, telemetering BPSK and FSK signal.With the rapid development of software radio technology and its application to the software processing of telemetry data later will become the future development trend in the field of remote sensing.

Keywords: WSN; Positioning Technology; non-ranging; RSSI; energy efficiency

Abstract. The self-positioning for the nodes is the prerequisite for wireless sensor network to work, especially considering that the deployment of underwater node changes rapidly in position. Taking the issue of energy efficiency and prolong the network lifetime into account, the energy-efficient positioning technology of the underwater acoustic sensor network is studied in this paper .Brief introduction of the current node positioning technology is concluded in this paper too. Similarly to the overlapping ideological positioning algorithm FTPL we introduce RSSI but not for the ranging. Also discuss the inadequacies of our new algorithm, and the possible improvements. Simulation results show that the improved algorithm has good improvement in both the accuracy and the energy efficiency.

Introduction

The underwater wireless anti-submarine sensor network has received great attention by the navy for its acclimatization in the information-based war, and thus has developed rapidly in recent years. Self-positioning for the nodes is the foundation for the anti-submarine network to achieve its tactical ability, and the precondition for the network's efficacy, therefore positioning technology is extremely crucial in modern war.

So far, there are various classifications for the node localization algorithms [1]. Below are the most common classification methods:

- Range-based v. Range-free localization algorithms [2]
- Anchor-based v. Anchor-free localization algorithms [3],
- Incremental v. Concurrent localization algorithms [3],
- Centralized v. Distributed localization algorithms [4],
- Fine-grained v. Coarse-grained localization algorithms [5] ,
- Physical v. Symbolic location algorithm [6].

Among them, the most widely accepted classification is range-based and range-free localization algorithms. There are four kinds of commonly used measuring technique: Time of Arrival (TOA), Time Difference of Arrival (TDOA), Angle of Arriva (AOA), Received Signal Strength Indication (RSSI), among them the RSSI application is the most widely used. Range-based algorithms require more hardware support, such as transmitting and receiving equipment, clock synchronization equipment etc. while range-free localization algorithms usually use the connectivity and geometric relations of the nodes to determine the location, instead of measuring the distance between the nodes. Thus range-free localization algorithms are of smaller hardware requirement and more energy saving. Centroid method [6], DV-Hop [7], Amorphous and APIT algorithm are some of the typical range-free algorithms. Under ideal conditions, range-based algorithms are more accurate than range-free algorithms, whereas for the anti-submarine network located underwater, clock synchronization in real situations can hardly be accurate. Thus, given the restriction of hardware and energy, range-free algorithms perform much better when the accuracy can be improved through the optimization method, which makes them widely used in underwater acoustic sensor localization.

FTPL Algorithm

Flexible Transmission Power for Localization algorithm (FTPL) [8] is a sensor node localization algorithm bring forward by Danlin Yao of National University of Defense Technology. FTPL suffers no influence of ranging error, and also consumes low communication overhead. The basic idea is to assume all anchor nodes in the wireless sensor network are the same with variable transmit power $(P_1, P_2, ..., P_n)$, and communication radius $(R_1, R_2, ..., R_n)$ corresponding to the anchor nodes' transmit power $(P_1, P_2, ..., P_n)$ of all the unknown nodes have been stored prior to network deployment. Each anchor node transmits a beacon signal at the minimum transmit power, and gradually increases the power. When the unknown node firstly received the anchor nodes' signal, the corresponding arc can be the outer boundary of possible regions for the unknown nodes, and the circle corresponding to the last launching signals as the inner boundary. When three or more such anchor nodes are found, centroid can be calculated as the position of unknown nodes.

The algorithm has obvious advantages, for those unknown nodes are totally inactive, thus the energy cost and communication overhead can be saved. If the network is in ideal condition, and the function between RSSI attenuation and the distance is well, FTPL is of high precision and easy performing.

However, this algorithm has the following problems:

1. FTPL takes no consideration of the uncertain signal attenuation problem. In fact, the attenuation of either underwater acoustic signal or ground electromagnetic wave signal, is largely caused by other uncertain factors in addition to the natural decay of distance, especially the underwater acoustic environment is indeed complex, when the uncertain issues are ignored, would certainly lead to the weaker received signal strength of the unknown nodes than the emission intensity, thus the radius calculated would be smaller. Once this happens, the positioning error can be quite big.
2. FTPL would discard the received signal when nodes receive signal, thus wasting the data, which is not expected during the data processing.
3. When an unknown node receives beacon message for a large number of anchor nodes, FTPL handle the case too simple by overlying these different circles.
4. FTPL takes no consideration of the sensitivity of nodes signal receiving. When the sensitivity of a node is low, it may miss the signal of weak strength, which thereby leads to the radius calculated bigger than real.

FTPL-3D

In this paper, we intend to locate the underwater nodes in three-dimensional space; however the original algorithm FTPL is based on two-dimensional plane. Whereas the basic overlapping idea of the original algorithm can be used for reference; here this algorithm is overlapping spherical shell.

FTPL-3D (Flexible Transmission Power for Localization in three-dimension space) stores the ID of anchor nodes and the signal strength corresponding to the transmission distance in advance, installs the pressure sensor to measure the depth information of the node. The anchor node broadcasts beacon information to the space instead of transmitting beacon signal to the plane, while the unknown node completely receives passive signal. When catch the anchor node A for the first time, mark the radius R_i corresponding to the firstly received signal as the outer radius of spherical shell, and R_{i-1} as the inner radius. Similarly, when received the signal of anchor node B, the inner and outer radius of another spherical shell can be gotten. Then modify the distance information to get more precise distance. Store the information of first received for later use.

As the entire anchor nodes are deployed at the bottom of the sea, none of connection between two nodes is vertical to the surface. According to the geometric relations, there must be three-dimensional rings not parallel to the surface of sea. Thus the pressure sensor measures the depth information, getting the plane overlap in the ring, calculate the centroid as the position of the node.

What need point out is, that the algorithm assumes that the sea anchor nodes have receiving device which can accept echo, which can help find which octant the unknown node is in the three-dimensional coordinate system which makes its own as the origin.

(1) Spherical Shell Radius Correction Algorithm

The underwater acoustic signal is inevitably influenced by lots of disturbance when propagating in water, thus the attenuation is very fierce, and the most causes of the decay are uncertain. Therefore we can only get the empirical formula of underwater acoustic signal propagating attenuation in the shallow water, obviously determining acoustic wave propagation distance would produce a big error only by experience formula, that is the factors the original algorithm takes no consider. This section will focus on solving the problem. We introduce the energy-consumption model of Cao Zhixin [9] as a reference.

The following is the empirical formula of acoustic signal propagation loss:

(1) Water absorption loss model:

$$\alpha = \frac{0.1f^2}{1+f^2} + \frac{40f^2}{4100+f^2} + 2.75\times10^{-4} f^2 + 0.003; \tag{1}$$

(2) Mixed layer channel propagation loss model:

$$\begin{cases} TL = 20\log r + (\alpha+\alpha_L)r\times10^{-3} \quad when \quad r < 350H^{1/2} \\ TL = 10\log r_0 + 10\log r + (\alpha+\alpha_L)r\times10^{-3} \quad when \quad r > 350H^{1/2} \end{cases} \tag{2}$$

(3) Propagation loss model of uniform shallow water channel:

$$\begin{cases} r < H: \quad TL = 20\log r + \alpha r\times10^{-3} + 60 - k_L \\ H \le r \le 8H: \quad TL = 15\log r + \alpha r\times10^{-3} + \alpha_r(r/H - 1) + 5\log H - k_L \\ r > 8H \quad TL = 10\log r + \alpha r\times10^{-3} + \alpha_r(r/H - 1) + 10\log H + 64.5 - k_L \end{cases} \tag{3}$$

where TL is the propagation loss, r is the effect distance(kilometer), α is sea absorbing coefficient(dB/km), H is the transition distance(kilometer), $H = [(D+L)/2]^{1/2}$, D is the depth of the sea water, L is the thickness of mixed layer channel(meter), α_r is the shallow water attenuation coefficient, k_L near field attenuation coefficient, α_r, k_L can be queried from the database according to the sea states and the geology.

Anti-submarine sensor network typically is deployed in coastal, and most of our China's offshore are shallow, which makes it possible for the formula (3), of course under the ideal sea state. Suppose that the attenuation caused by uncertain issues is $LOSS$, we can modify the algorithm as follow.

Considering that the different strength signals from one same anchor node to another same unknown node have the same propagating ways, thus the same interferences they would experience, that will make the same attenuation which is $LOSS$, then followed such formula:

$$P_i = P_{Ri} + \mathrm{TL}_i + LOSS \tag{4}$$

Where P_i represents the signal strength of the anchor nodes send, P_{Ri} represents the signal strength of position nodes received. As those unknown nodes have already stored the ID of anchor nodes and the signal strength in advance, P_{Ri} is known as a result. Thus among the propagation loss TL only R remains unknown, P_i is unknown either.

According to the idea of mathematical equations, simultaneous any three of them can help get the real distance R. In the actual operation of the process, we calculate arithmetic mean of the multiple sets of numerical result, which would help to make the result closer to the actual value.

(2) FTPL-3D-F

FTPL-3D-F (Flexible Transmission Power for Localization in three-dimension space based on data fusion), the algorithm is the further upgrading to FTPL-3D after taking data fusion in account. FTPL-3D-F behaves well as it can handle many issues such as distance from different anchor nodes to the unknown nodes, or the self-construct of anchor nodes.

When an unknown node received signal from many (no smaller than 4) anchor nodes, each three of the spherical shell can built an enclosed area, plus the depth information measured, that is each three anchor nodes gives out a centroid. The question is which one is the optimal; do we need comprehensive treatment to all the results; and how to choose anchor nodes from the candidates. That's what we are trying to solve in this chapter.

Two conclusions emerge from these general statements:

1) When the exact location cannot be found, then the smaller region the point may exist, the higher possibility the true location it can be.

2) Under the same area, shapes close to the equilateral triangle, square and other similar angles about the size, capered with those of narrow angle, angles in different size of more, the former can provide more accurate location estimated than the latter. At least in the probabilistic perspective, possibility of the former position is more accurate and higher.

The estimation of unknown nodes in the former location is more accurate than the latter, at least in the probabilistic perspective, possibility of the former position information more accurate and higher.

There are obvious geometrical meanings of the above conclusion, here without proof.

The basic idea of FTPL-3D-F is: when the unknown node can receive the signal from a lot of anchor nodes, exhaustive three combinations, judge the shape that every three anchor nodes formed from the overlapping region shape, calculate the centroid of the region as a possible location point; then give different weights to the results according to their shape and area, calculate the weighted average as the final result.

(3) Weight selection

As in the model of underwater acoustic signal propagation path loss, numerical value of RSSI is similar inverse proportion function with the distance between, that is the value decrease with distance. At the same time, there may be more interference of underwater acoustic signal propagation process. Attenuation compensation mentioned above is just an experience formula, may not be perfect compensation. Therefore, in the actual process of anchor nodes positioning, the closer the distance, the smaller the radius error. So when setting the weight, we assume it inversely proportional to the ball shell radius, which makes the positioning accuracy proportional to $1/R_1 + 1/R_2 + 1/R_3$.

The larger the overlap area is, and the more long and narrow shape is, the bigger the node location measuring error is, that is the weight is inversely proportional to the area. We can judge the shape from the point's distance deviation of the overlap region boundary. The bigger the distance deviation is, the narrower the shape is. That is the positioning accuracy is proportional to the overlap area S, proportional to $1/(L_{\max} - L_{\min})$, where $L_{\max}, L_{\min}$ represents the maximum and minimum value of the overlapping regions vertex distance.

What need point out is that the process of weight selection is lack of rigorous mathematical reasoning calculation; we estimate the weight according to the geometric intuition, for the lack of good methods of selecting weight as to the information available at present. Our assumption is yet helpful to enhance positioning accuracy.

Here are the operation steps of the algorithm of FTPL-3D-F:

Step 1.Determine the depth information of the unknown nodes;

Step 2.After the unknown node receives the signal, judge the anchor node ID and the inner and outer radius of the spherical shell;

Step 3.Catalogue all combination of each three anchor nodes, get the coordinates of boundary points for each overlapping area according to the depth of the plane where position nodes identify , each anchor node position and radius of the spherical cavity;

Step 4.Judge the shape of each overlap region, and calculate the area;

Step 5.Calculate centroid of each anchor nodes combination overlap region, serve as an unknown node coordinate values, obtain a set of coordinate values;

Step 6. Calculate the weighted average of the resulting data as the node coordinates.

Simulation Test

The simulation conditions are: in a room of 100*100*100, generate a random coordinate of unknown nodes, and then randomly generate four anchor nodes coordinates (Z=0, means the anchor nodes usually deployed at the bottom of the sea), add in random interference. We did multiple tests for location calculation using FTPL algorithm and the FTPL-3D-F algorithm respectively. Figure 1 below gives the comparison of positioning accuracy of the two algorithms, where the *vertical axis* represents the error, which is defined as the distance from the actual location to the calculated location while the *horizontal axis* represents the difference of different radius. Compared of precision curve of the two algorithms, it is obvious that the FTPL-3D-F algorithm significantly improves the positioning accuracy.

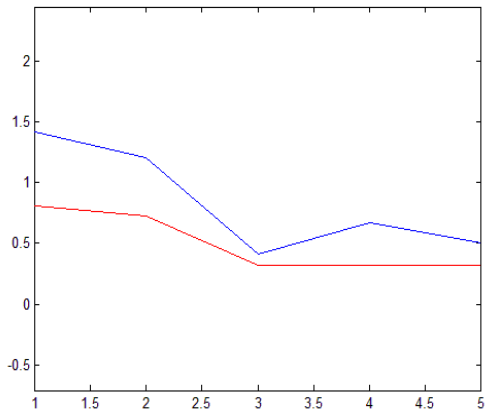

Fig. 1 Comparison of positioning accuracy of FTPL and FTPL-3D-F

Notes: Blue curve represents the error of FTPL while red curse represents the error of FTPL-3D-F

As is shown in the figure, our accuracy of the FTPL has directed relationship with the difference of radius. The smaller the difference is, the more accurate the result is. Theoretically, the smaller the radius difference is set, the smaller the volume of the sphere overlap is, and thus more accurate the centroid as the node's coordinates. When the radius difference is infinitely small, FTPL-3D turns out to be range-based Three-point positioning method, which has the highest accuracy in theory. However such infinite can hardly be reached, for the difference of power cannot be that small, let alone that such difference set would increase the economic costs for the excessive demands on the hardware. Then more information to be saved for the smaller difference, and nodes burdened with heavy storage is not suitable for underwater acoustic wireless sensor network.

FTPL-3D-F is an improvement for FTPL-3D based on data fusion, however compared with FTPL, under the situation of same difference; FTPL-3D-F has a more obvious improvement than FTPL for larger one. FTPL-3D-F takes the shape of the overlap area, the volume size and other issues into consideration, which makes it less sensitive to the change of radius difference. Numerous tests proved our conclusion with larger radius difference.

After large number of experiments, we found FTPL-3D-F is not always better than FTPL-3D. The former consider the issue of the shape and volume size of the overlap area and the distance to anchor nodes, but these can only improve the possibility of high accuracy, thus low accuracy turns out occasionally. We state that not an error in our data fusion but the shortage of algorithm.

Conclusions

To improve the accuracy of range-free localization algorithms, we expand FTPL algorithm, continue to use the idea of RSSI strength but abandon the idea of practically measuring distance, and therefore avoid the complex problem of clock synchronization effectively. Meanwhile our algorithm conquers the limit of localization algorithm caused by the influence of uncertain issues such as complex underwater acoustic environment and large quantitates of noise and interference. We improve the FTPL algorithm, and do the processing of data fusion aimed at the multi anchor node localization algorithm, and after experimental verification, both improvements help to improve the accuracy and adaptability of the algorithm.

There are still improvement rooms for the algorithm we give out for data fusion. Our algorithm can improve accuracy in most cases in many measurements, however further study is focus on the higher accuracy for each of the measurement. Besides, for the nodes with low sensitivity , the nodes can only receive Signals with high strength, that would cause large error. Both algorithm are weak in this case, method to improve the sensitivity and the auxiliary positioning of AUV and UUV may help.

Keywords: Power system communication network, alarm management, CORBA

Abstract. With the development of communication technology, the increasing scale of power communication network is bigger and bigger. Based on the important significance of electric power communication network to establish an alarm information acquisition system is necessary. CORBA, as a distributed processing environment interconnect solutions in hardware and software, is widely used in the field of network management for its high versatility. In this paper we use real-time CORBA platform TAO as a network management platform to develop a kind of electric power communication network alarm acquisition system.

Introduction

Electric power communication network is one of the national special communication network and an indispensable important part of power system. It is the foundation of the power grid dispatching automation and marker-oriented operation [1]. Therefore, on the basis of original network management system to establish integrated alarm information processing platform is very important.

The article is as an example of CORBA northbound interface and detailed analysis the application of CORBA technology in the northbound interface. So we put forward a design scheme based on CORBA northbound interface and realize the acquisition of SDH transmission network alarm information in the TAO platform.

CORBA overview

Common Object Request Broker Architecture (CORBA) defined by the object management group (OMG) is a language-independence object interoperation model in heterogeneous environment platform. In an object-oriented distributed computing environment, an object request proxy can provide key communication facilities between applications, servers and network facilities for distributing message.

The design of northbound interface based on CORBA system. The overall structure of northbound interface is mainly divided into two layers. Near the EMS is data adapter layer. The layer mainly realizes EMS package and information model processing. Near the NMS is agreement processing layer. The layer mainly realizes the CORBA object implementation, parameter analysis and report processing module. In addition, the layer can generate structured events and passes the events to the client through Event Channel [2]. The structure of northbound interface is shown in figure 1.

The overall design of system. The realization of alarm acquisition function is the foundation of alarm integrated management system. According to the alarm information processing, the function structure of whole system can be divided into three layers, including: alarm information collection layer, alarm information analysis processing layer and alarm information reporting storage layer.

Alarm information collection layer

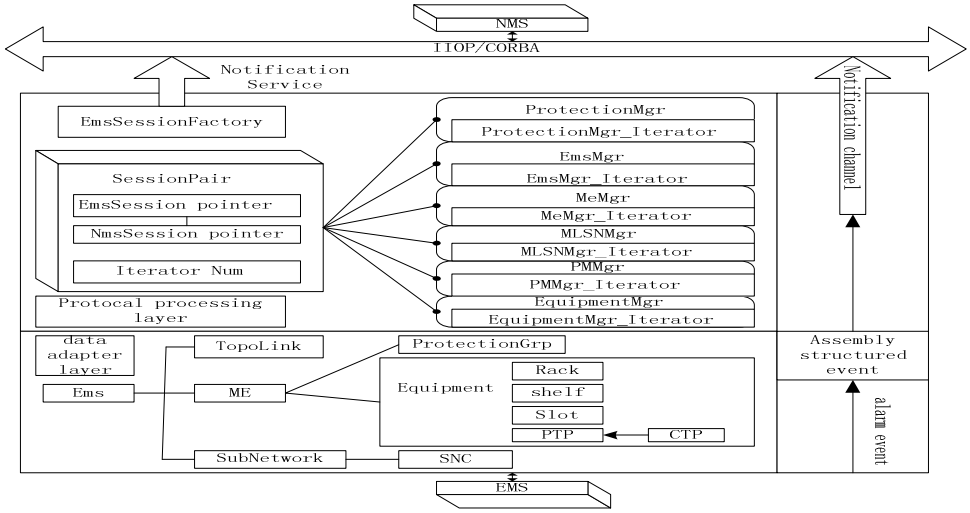

Fig. 1 The structure of northbound interface

Establish session interface. To complete alarm information collection, the system first needs to realize communication between NMS and EMS. In the building of session interface, EmsSessionFactory interface calls the only function getEmsSession to get EmsSession interface. Each manager can be obtained through EmsSession. In the meantime, NmsSession parses names by naming service and gets object reference registered under EmsSessionFactory to realize the establishment of the NMS - EMS session [3].

The process of alarm information acquisition. The system mainly realizes electric power communication network alarm information acquisition based on CORBA northbound interface. The main means used in collecting alarm interface are naming service and notification service in CORBA interface mode.

In the network management of alarm collection, alarm information collection can be divided into two parts, for respectively the real-time alarm collection and the non real-time alarm collection. The alarm information collection process is shown in figure 2.

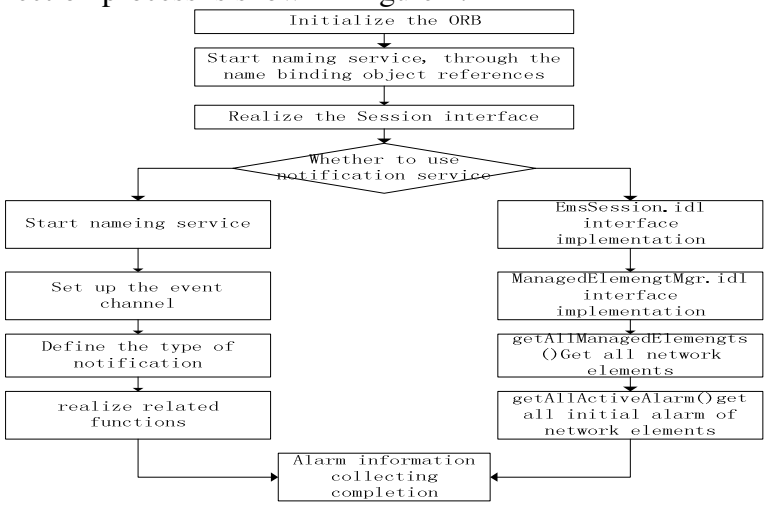

Fig. 2 The process of alarm information collection

CORBA notification service can realize real-time alarm information collection. Notification service with its own unique management quality of service can obtain real-time alarm information collection to establish event buffer queue.

Using the method of ManagedElement_I can realize non real-time collection of alarm information network elements. The ManagedElement interface provides getAllManagerElements and getAllActiveAlarms function to realize alarm collection[4] . Function call sequence diagram is shown in figure 3.

Alarm information analysis processing layer. The collected alarm information can give operation staffs huge interference because of its rich content. You have to gather alarm data of refining and normalized for pretreatment. As a result, the different formats of alarm information can be converted into key alarm information's unified format which is needed by the system and then passed key alarm information to the application server. Key alarm information mainly includes network elements ID, alarm name, alarm object name, alarm object type, alarm time and alarm status.

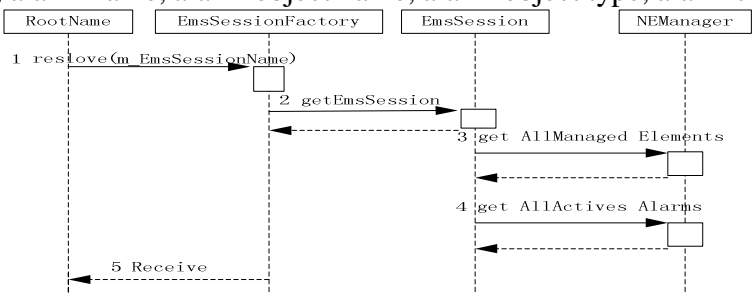

Fig. 3 The function call sequence diagram

Alarm information reporting storage layer. In the completion of alarm information analysis processing, the alarm information is stored in the database by the ODBC source for later alarm statistical analysis and then send the unified format of alarm information to the cache space which will form alarm sent queue [5]. By using CORBA notification service event channel can realize the alarm information sequentially take the initiative to report to the backend server.

Notification service inherits the event service of Push and Pull two communication modes. In Push mode, notification provider actively push notification to consumers; In Pull mode, notification consumer pull the notification from the providers .In actual system we usually choose Push mode. Realizing a Push mode for events sending contains two aspects. First, connect provider to the event channel. Second, connect consumers to the event channel [6]. This process is shown in figure 4.

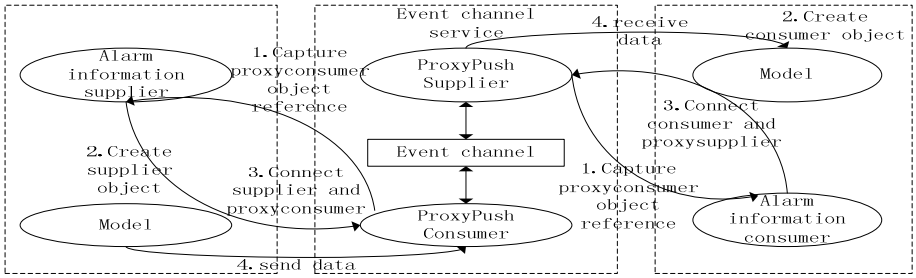

Fig. 4 The process of push model event transmission

The result of alarm acquisition system

The TAO platform can realize the alarm data collection. The alarm collection display interface is shown in figure 5.

	AlarmSerialNo	NOTIFICATIONID	OBJECTNAME	NATIVEEMSNAME	NATIVEPROBABLECAUSE	OBJECTTYPE	EMSTIME	NETIME	ISCLEARABLE	LAYERRATE

40	24061782	41218400334179	EMS =	Huawei/T2000;1000-	CP_SER_NOT_OR	9	20130415033028	20130415033026	1	1

Fig5. The display of collection interface

Alarm information collection display interface shows the alarm information according to the standardized format. Putting alarm ID in the first place can improve the processing efficiency of alarm information. The real-time display of different network management alarm information can accomplish the alarm information collection which will achieve the purpose of the system.

The test of alarm acquisition system

In order to verify the design of CORBA northbound interface alarm data acquisition system, it is necessary to carry out the functional test. It is mainly from the alarm reporting function to carry on the CORBA alarm interface test so that the correctness of the interface can be well verified.

Test project: alarm report function. Testing purposes: northbound interface should support manufacturer network management system report all real-time alarm to transmission network management system, the creation and disappearance of alarm should come in pairs.

Testing expected results: northbound interface supports manufacturer network management system report all real-time alarm to transmission network management system, the creation and disappearance of alarm come in pairs [4].The content of test is shown in Table 1.

Table 1.Details of alarm report function test

Parameter name	Interface parameter names	Date type	Value instructions	Test result
Event type	Event_type::type_name	String	Type_name must be NT_ALARM	OK
Alarm identifer	NotificationId	String	Notification event unique ID number	OK
Alarm source object types	ObjectType	Notifications::ObjectType_T	The reported alarm of object types	OK
Alarm level	PerceivedSeverity	Notifications::PerceivedSeverity_T	Critical alarm Major alarm Minor alarm Warning	OK
Alarm reason	Probablecause	String	Defined alarm probable cause	OK
Alarm time of ems	Globaldefs::Time_T	String	The time value of EMS to report events	OK

Summary

Based on the reusability and portability of CORBA, the TAO platform realizes alarm information collection, alarm processing and alarm report management .The implementation of alarm information acquisition system can improve the reliability of electric power communication network which will promote the automation and centralization of power grid.

Keywords: communication networks; complex networks; robustness

Abstract. The robustness of customer service system for telecommunications industry is researched. To overcome existing robustness defect of node failure in current network robust research model, node efficiency assessment of robustness is employed, generalized evolution theory is taken into, and changes process of telecommunications customer service systems is simulated. In analysis of conditions in different interference, robustness performance is presented. Simulation results show that the method considering the telecommunications industry to build robust customer service system is feasible and effective for large, complex networks, which has a good capability of computing power.

Introduction

Robust has meanings of a rugged, durable, robust. Capacity, reliability, redundancy is conducive to improve the robustness enhancement [1]. In operation, communication network is usually disturbed or damaged, leading to loss of function or decrease of performance. Robust communication networks become an important feature of network research [2]. At present, robust wired networks is mostly focused on in international field, but wireless communication network nodes become failed node due to random failures or malicious attacks [3]. Wireless failed node will lead to networks split, leading to network performance degradation and even complete loss of the network [4-6]. Measurement robustness method is presented, considering the efficiency of communications networks. Firstly, it employs efficiency of original network nodes to define to load of each node and limit load, according to changes in the network before and after the attack to determine load function of node failure model; then gives robustness assessment algorithms of network function and optimizes. Finally, experimental analysis is used to verify its effectiveness and feasibility.

Construction of communication system network model

A.Theoretical support of network communication system

Current research methods of robust communication system are based on the shortest path of network nodes, based on network connectivity, which are both based on research of network topology but ignoring network functions robustness. It is affected by not only actual operation of network system topology, but also capacity constraints of the node itself. For example, information transmission of in communication network should consider load information of each node. Once transmission overloads of information node in communication network, it will also lead to collapse of the entire network. For a simple communication network (side right of adjacent nodes are l) shown in Fig 1 if failure of the node V1 occurs, communication load of subnet A and B on the entire are superimposed on V2, communication network connectivity will be destroyed.

It is seen that in study process of complex networks robustness, network topology considerations alone is not enough, because removing nodes or edges can lead to redistribution of flow information throughout network and node load changes in the information transmission process. For actual network system, node failure on the network is global, and not just affects neighbor nodes. As FIG l node V1 failure affects node V2. Connectivity is not just the physical connectivity, but also considers in the actual system load range of capacity constraints. Even

physical side suffers a blow, as long as the node has sufficient resources, it will maintain its existing function by other means. However, if the node is overloaded, it will also lead to collapse of network.

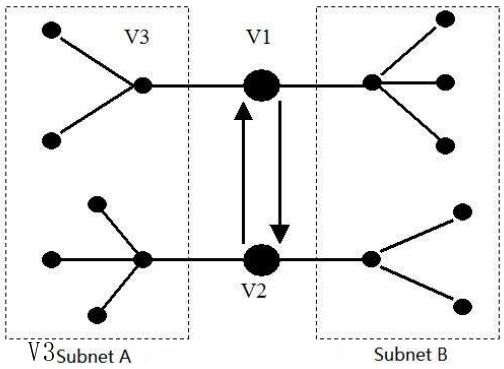

Figure1 Information distribution of schematic communications network

B.Establishment of a communication system network model

Figure G = (V, E) represents a communication system network, wherein V means the set of nodes, E represents a set of edges. | V | is number of nodes in the set, considering edges in the graph is undirected edges. If a subgraph G '= (V', E '), V' ∈ V, in V 'between any two points there is an edge, G' is a connected subgraph of G. If the graph G = (V, E) consists of connected subgraph structure, denoted G1 = (V1, E1), G2 = (V2, E2), ..., G1 = (V1, E1), then G1, G2, ... , G1 of G is called connected component. If V '∈ {V1, V2, ..., V1} and

$$|V'|=\max\{|V_1|, |V_2|, \ldots, |V_1|\} \tag{1}$$

Called G' = (V ', E') is the largest connected component of the graph G. Note

$$C=\frac{|V'|}{|V|} \tag{2}$$

G′ is coverage rate of G.

Definition1: In the node network model G = (V, E), number of nodes | V | = n, delete Nr (n) node, the remaining sub-graph consisting of m-branch communication, G1 = (V1, E1), G2 = (V2, E2), ..., Gm = (Vm, Em), 1 ≤ m ≤ Nr +1, the number of nodes available to Am (n) = max {| V1 |, | V2 |, ..., | Vm | }, if the coverage Cm (n) satisfies the equation:

$$\lim_{n\to\infty} C_m(n)= \lim_{n\to\infty} \frac{A_m(n)}{n}=1 \tag{3}$$

It is claimed that Figure G = (V, E) can tolerate the failure of Nr (n) nodes.

Assuming activity cluster head node proportion of all points is p(n), recording number of failure nodes as Nr (n), failure nodes may be a cluster head node or may be an ordinary node. Set number of failure cluster head node as N_{r1} (n) and number of failure ordinary nodes as N_{r2} (n). The N_r(n) can be expressed as:

$$N_r(n)=N_{r1}(n)+N_{r2}(n) \tag{4}$$

Failed cluster head node is represented as the proportion of total number p_1 (n), namely:

$$p_1(n)= \frac{N_{r1}(n)}{N_r(n)} \tag{5}$$

When failure is caused by random failures, failure probability of all nodes are the same, so p1 (n) = p (n); When the failure is caused by malicious attacks, failed nodes are mainly in the cluster head, so p1 (n) = 1.

Definition2: In the node network model G = (V, E), number of nodes V = n, the probability of active nodes is p(n), optionally N_r (n) nodes, wherein the proportion of active nodes is p1 (n), p_1 (n) is determined by the formula(4), (5). If Figure G = (V, E) can tolerate Nr (n) failure nodes, when p1 (n) = p (n), figure G = (V, E) is the Nr (n) fault-tolerant, when p1 (n) = 1, Figure G = (V, E) of Nr (n) invasion-tolerant.

Simulation experiments and result analysis

In the telecommunications industry, customer service system, for example, employs simple communication network structure as shown in Figure 1. With network connectivity and maximum size of subnet connectivity indicators, customer service system robustness of telecommunications network are simulated while V1, V1 and V2 both fails, experimental results are shown in Table 1 (average of multiple simulation).

Table1 Robustness results of telecom customer service system

Assessment index	Failure nodes	V1	V1，V2
Topological robustness	Network Connectivity	connected	disconnected
	Maximum Connectivity subnet model	14	12
Functional robustness（α=1， β=1.5）	Network Connectivity	disconnected	disconnected
	Maximum Connectivity subnet model	15	0
Functional robustness（α=∞）	Network Connectivity	connected	disconnected
	Maximum Connectivity subnet model	15	14

As can be seen from Table 1, when α=∞, robustness results of network function and assessment results of topology robustness are the same; Whenα=1，β=1.5, above results are different. The reason is that robustness of network function considers withstanding load of communication network node. It can be seen that, it is more accurate to consider network topology, capacity of nodes and robust assessment.

For robustness of complex networks, it is generally considered in the random attack. Random scale-free networks have a stronger network fault tolerance; but in a deliberate attack, scale-free network is extremely fragile. Experimental results of function robustness for communication network can be shown in Figure 2.

As can be seen from Figure 2, when tolerance factor α of network node load and load limit of coefficient β increases, function robustness of communication network is gradually increased. When α=∞, function robustness of communication network is stabilized, indicating that there is no failure node caused by overload in communication network. Besides hit node, the other nodes can maintain its existing communications capabilities, in communications networks at this time functional robustness is strongest.

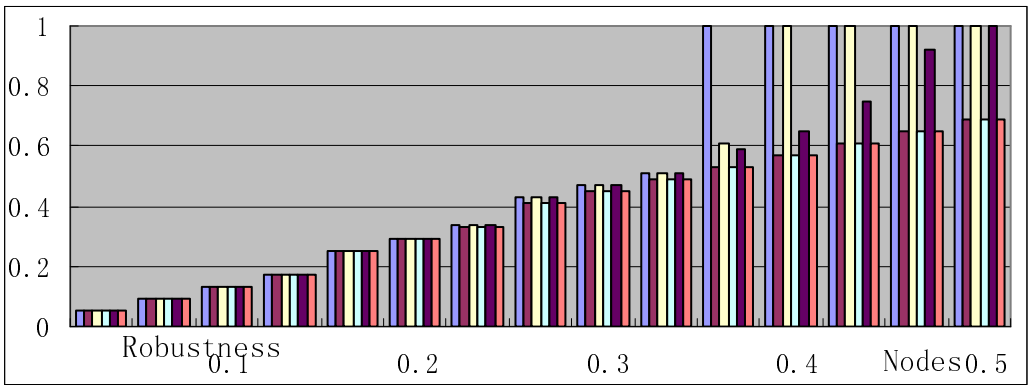

Figure 2 Robust schematic of communications network

When α and β values are fixed, on the whole: communication network in response to deliberate attack on its functional robustness is low with strong fault tolerance; different ways of attacking is little affected to random communication network, which is consistent with the conclusions of classic experiment, indicating the effectiveness of this method.

Conclusions

Detailed analysis is performed for robustness of telecom customer service system. In view of network robustness assessment model, assessment of network robustness is presented considering nodes efficiency of global network information. Experimental results show that of telecommunications customer service system is constructed, not only assessment of actual network topology, but also withstanding load of nodes. This method can be used to guide the telecommunications industry to build customer service system and solve specific issues in system control of telecommunications industry customer service.

Keywords: Cryptosystem, Image encryption, Elliptic curve, Arnold cat map.

Abstract. For decades, symmetric cryptosystems, such as chaos-based ones, are designed for image encryption. In this paper, a novel public key scheme for image encryption is presented. Based on the improved elliptic curve cryptosystem and Arnold cat map, the novel scheme can offer high security while avoid exchange and distribution of secret keys. The experiments illustrate that the presented scheme is computationally less complex than the traditional asymmetric cryptosystems and suitable for large image encryption.

Introduction

Nowadays, images play a critical role in people's private life. Consequentially, efficient image encryption methods are in great demand. Asymmetric cryptosystems, such as RSA [1], can hardly be directly used for image encryption because of the large image size. On the other hand, a number of symmetric image cryptosystems are developed [2]. Most of them rely on chaos-based maps [3]. However, chaos-based symmetric cryptosystems have intrinsic difficulty of exchange and distribution of secret keys [4]. In addition, most chaos-based maps require floating point operation and considerable iterations which is time consuming.

In this paper, a novel public key image scheme is proposed to overcome the problems above. Based on the elliptic curve cryptosystem (ECC), our scheme can solve the difficulty of secret keys management. Also, our scheme requires much less time and storing space than typical ECC because of the use of nonlinear operation as well as Arnold cat map.

This paper is organized as followed: in the next section, ECC and Arnold cat map is briefly reviewed. In section 3, our scheme is put forward. In section 4, experimental results are discussed. In section 5, we give the conclusion.

Elliptic Curve Cryptosystem (ECC) and Arnold cat map

ECC was developed by Koblitz [5] and Millier [6] in 1980s originally. Its security is based on the difficulty of solving the Elliptic Curve Discrete Logarithm Problem (ECDLP). Let p be a large prime number, and$E(F_p) = \{(x,y)|y^2 \equiv x^3 + ax + b(mod\ p), x, y \in F_p\} \cup \{O\}$. The parameters $a, b \in F_p$, *s.t.* $4a^3 + 27b^2 \not\equiv 0(mod\ p)$. O is the point at infinity. $E(F_p)$ is called an elliptic curve in finite field F_p. ECC is established based on elliptic curve $E(F_p)$ and point addition together with scalar multiplication defined on $E(F_p)$. Compared to RSA, ECC requires much shorter keys to maintain a same security level [7]. Hence, ECC occupies smaller space and consumes less time than RSA. However, the typical ElGamal ECC has two difficulties. One is that the message must be represented by a point in $E(F_p)$. The other is that ECC should not reuse keys to assure the security. As a result, it is still inefficient to apply ElGamal ECC directly for image encryption.

Arnold cat map is a two-dimensional invertible chaotic map [8] for an *N*x*N* image. In Arnold cat map, there are three parameters, *c*, *d* and *s*. *c* and *d* are integers in *{0, 1, 2,..., N-1}*. *s* is the number of iterations. Arnold cat map has high computational efficiency, though, its periodic property and disability of changing the histogram weakens its security.

In the next section, we propose a novel public key cryptosystem based on improved ECC and Arnold cat map to cipher large image more effectively without compromising the security.

The Proposed Image Encryption Scheme

In this section, we propose a public key scheme for large image. Suppose Bob wants to send a large image $X_{n\times n}$ to Alice, and that the dimension of the image is $n \times n$.

Key Generation. Alice chooses a large prime p, an Elliptic Curve $E(F_p)$ and a point $P \neq O \in E(F_p)$ carefully. Then she chooses a large secrete random number $k_a \in [2, p-2]$ and computes $Q = k_a P$. $(E(F_p), P, Q)$ is the public key and k_a is the private key. Alice should keep k_a secret.

Encryption. Bob encrypts the image as followed:

1) Select two large random numbers k_b and k_c as his private keys.

2) Compute

$$K_0 = k_b Q = (x_0, y_0). \tag{1}$$

$$L = k_c Q = (x_L, y_L). \tag{2}$$

$$R = k_b P. \tag{3}$$

$$S = k_c P. \tag{4}$$

3) Generate the key matrix K_M_{nn} with the following algorithm:

Algorithm 1 *Key Matrix Generation*

Input	***Output***
$K_0 = (x_0, y_0), L = (x_L, y_L), n$	K_M_{nn}

```
1:  Keyseq ← null
2:  i ← 0
3:  K = (K1, K2) ← (x0, y0)
4:  while length(Keyseq) <n^2 do
5:      i ← i + 1
6:      K ← K + K
7:      l ← length(K1⊕yL)
8:      Keyseq ← shiftleft(Keyseq, l)
9:      Keyseq ← Keyseq + K1⊕yL
10:     l ← length(K2⊕xL)
11:     Keyseq ← shiftleft(Keyseq, l)
12:     Keyseq ← Keyseq + K2⊕xL
13: end while
14: for i ← 1 to n do
15:     for j ← 1 to n do
16:         ptr ← (i − 1)n + j
17:         K_Mnn[i, j] ← Keyseq[ptr]
18:     end for
19: end for
20: return K_Mnn
```

4) Compute

$$c \equiv x_0 (mod\ n). \tag{5}$$

$$d \equiv x_L (mod\ n). \tag{6}$$

$$s \equiv y_0 \oplus y_L (mod\ n). \tag{7}$$

$$C_{nn} = \big(Arnold\ cat\ map(X_{nn} + K_M_{nn}, c, d, s)\big) \oplus K_M_{nn}. \tag{8}$$

Now, Bob can send (R, S, C_{nn}) to Alice.

Decryption. Once received (R, S, C_{nn}), Alice decrypts the image as followed:

1) Compute

$$K_0 = k_a R = (x_0, y_0). \tag{9}$$

$$L = k_a S = (x_L, y_L). \tag{10}$$

2) Apply *Algorithm 1* to obtain the key matrix K_M_{nn}.
3) Use (5), (6), and (7) to obtain *c, d* and *s*. Then compute

$$X_{nn} = \left(Inverse\ Arnold\ cat\ map(C_{nn} \oplus K_M_{nn}, c, d, s)\right) - K_M_{nn}. \tag{11}$$

Experimental Analysis

In this section, some experimental results are discussed to illustrate the security and efficiency of our scheme.

Security Compared to Arnold Cat Map. In Fig.1, LENA.BMP, a 256x256 size gray picture, is encrypted within our scheme and directly using Arnold cat map, respectively.

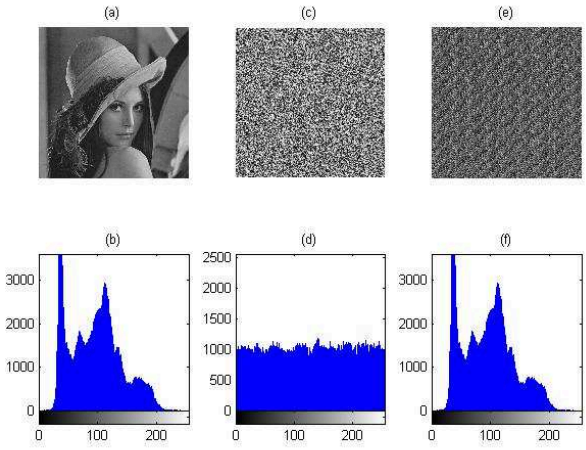

Fig.1 (a) original-image LENA; (b) the histogram of LENA; (c-d) Encryption of LENA using our scheme and the histogram; (e-f) Encryption directly using Arnold cat map and the histogram

Fig.1 shows that our scheme is more secure for image encryption than Arnold cat map. The histogram of the encrypted image resulted from our scheme is like white noise while that generated directly by the Arnold cat map is exactly the same as that of the original image.

Efficiency Compared to ECC. Our scheme and ECC are used for encryption of four different images, respectively. Fig.2 shows the comparison of encryption time and cipher image size.

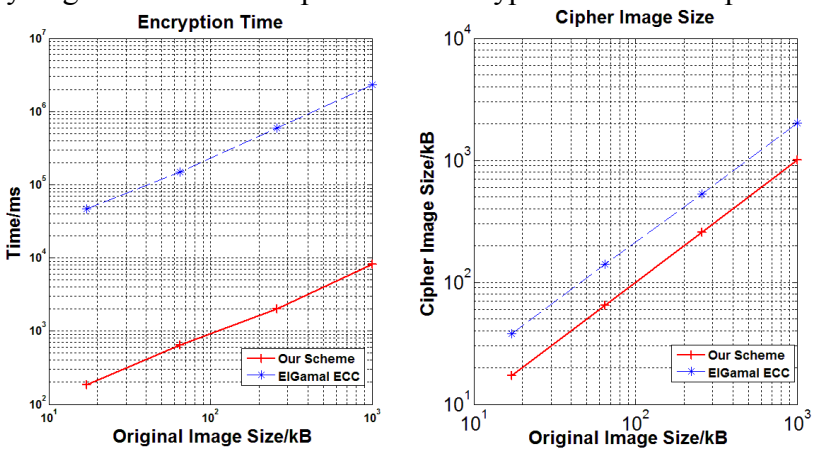

Fig.2 The comparison between our scheme and ElGamal ECC

Fig.2 demonstrates that our scheme requires much less encryption time and occupies smaller storing space than ECC. The larger the image is, the more efficient our scheme will be.

General Security Analysis. The security of the presented scheme essentially relies on ECDLP. Thus, it is difficult for an intruder to compute k_a, k_b and k_c from public keys. Because of the XOR operation and Arnold cat map, even if the adversary knows a part of the original image, he/she can hardly obtain the key matrix so that no other parts can be acquired. Therefore, our scheme can resist chosen-plaintext attack.

Conclusion

In this paper, we propose a fast public key scheme for large image encryption. The scheme is based on improved ECC and Arnold cat map. It is shown that our scheme can avoid the exchange and distribution of private keys, require much less time than typical ECC and guarantee a high security level. This scheme is suitable for massive confidential image exchange in open network.

Research on Adaptive Face Gender Recognition Based on Compressive Sensing

Zhang Lin

Jiangxi Science & Technology Normal University, Nanchang, China

zlhaze@aliyun.com

Keywords: Compressive Sensing, Adaptive, Feature Extraction, Gender Recognition

Abstract. An adaptive gender recognition method is proposed in this paper. At first, do multiwavlet transform to face image and get its low frequency information, then do feature extraction to the low frequency information using compressive sensing (CS), use extreme learning machine (ELM) to achieve gender recognition finally. In the process of feature extraction, we use genetic algorithm (GA) to get the number of measurements of CS in order to gain the highest recognition rate, so the method can adaptive access optimal performance. Experimental results show that compared with PDA and LDA, the new method improved the recognition accuracy substantially.

Introduction

The rapid development of computers has had a huge impact on human society today. In many areas, the computer is increasingly toward intelligent, and gradually replace humans do a lot of challenging work. In order to be more flexible and convenient communication between computers and humans, to achieve human-computer interaction is inevitable development. As the most obvious biological features of human, face image contains a lot of information, we can get gender, age, race, identity and other information [1]. Compared with other biological features, face features are naturalness, convenience and non-contact [2] which make gender recognition based on face features got some development. Gender recognition research has a very wide range of applications [3-5]. Firstly, gender recognition is an important research field of intelligent man-machine interfaces which let the computer to understand face information and classify. If it can achieve a certain degree of intelligence, the current inflexible, inconvenient interactive environment will be improved greatly. Secondly, gender recognition can provide the necessary sex information for a number of users which provide the basis for the user to make decisions based on the information. Thirdly, with the increasing emphasis on security, gender recognition can also play a huge role in security systems, authentication, etc. In addition, gender recognition has good application prospects in population information collection, population statistics, image retrieval, ect.

Therefore, a series of studies on gender recognition and further improve is very necessary. In this paper, we consider using CS in feature extraction of face gender recognition. The appearance of CS brought great changes to feature extraction. Optimal feature selection is no longer a key issue, substantial decline of calculation and good discrimination of sparse representation of signal is very exciting [6]. This paper is organized as follows. Section 2 introduces some background information of this method including CS and ELM. Section 3 gives a detailed description of the proposed method. Experimental results and analyses are shown in section 4. Section 5 gives the conclusion.

Background Information

Compressive Sensing. CS is proposed by proposed by Candes and Donoho in 2006 [7] which revolutionized the tradition. This theory combines with sampling and compression to break through the bottleneck of the Nyquist-Shannon sampling theorem. The advantage of CS is that the number of measurements of signal is far less than the Nyquist-Shannon sampling theorem which makes the process of broadband signals is more efficient. Therefore, the theory will help people easing the pressure of hardware facility from the requirements of the huge amount in information processing

[8] and can effectively carry valuable information in the signal which ensures accuracy in signal transmission, signal processing and reconstruction.

Extreme Learning Machine. Most existing learning algorithms are much slower and cannot satisfy the requirement. Aiming at this shortcoming, Huang and Zhu proposed Extreme Learning Machine (ELM) in 2006. Comparing with most learning algorithms, ELM has extremely fast learning speed, better generalization performance and is much simpler. ELM works for generalized single-hidden layer feedforward networks (SLFNs) which randomly chooses hidden nodes and analytically determines the output weights of SLFNs [9,10]. ELM tends to reach the smallest training error and norm of output weights [11]. Different from the traditional learning algorithm, the hidden layer in ELM need not to be iteratively tuned. ELM requires milder optimization constraints and less human intervention [12].

Based on the advantage of ELM, we consider using ELM in our new method. ELM can be described as follows [10,13]: Suppose given a training set Y, activation function G and hidden node number M. At first, randomly assign input weight a and bias Ψ. Secondly, calculate the hidden layer output matrix H. Finally, calculate the output weight ω via ordinary least-square.

The Proposed Method

Multiwavelet is developed on the basis of wavelet, it is a wavelet generated by scaling function which is composed of more than one function. Multiwavelet expands multi-resolution analysis of space generated by single scaling function of wavelet to space generated by several scaling functions of multiwavelet. Multiwavelet retains many of the advantages of wavelet and perfectly combines smoothness, short support, orthogonality, symmetry, ect. [14], so it has gained widespread attention. GA is proposed by Holland in 1975 which is an optimization method that simulates the natural selection of Darwin's evolution theory and biological evolution process of genetic mechanism which combines the survival of the fittest theory of Darwin and random exchange theory. The survival of the fittest theory can eliminate the inappropriate factor of solution and random exchange theory use existing knowledge of the original solution which speed up the search process for the optimal solution [15].

We know that most important information of a signal after multiwavelet transform focus on low frequency information. So we can directly extract feature from low frequency information replacing original signal to reduce the computational time of algorithm. In CS, the number of measurements M has a great influence to performance. Because the value of M must be integer, we use integer programming GA to ensure the value of M in our method.

The proposed method can be described as follows:

Given some face images, multiwavelet basis, a measurement matrix Φ

Step 1: read training images and testing images, do pre-treatment and normalized to them

Step 2: do multiwavlet transform to training images and testing images, gain low frequency information, we select Sa4 multiwavelet basis here

Step 3: create a N*M measurement matrix Φ obeying Gaussian distribution (0,1/M) , do CS to low frequency information to extract feature. In this step, the selection of the number of measurements M will ensure via GA which will be described below

Step 4: enter feature of training images into ELM to do learning, then enter feature of testing images into ELM to do face gender recognition, output the recognition rate

The process of GA in step 3 is shown as follows:

Step 1: determine the parameters set of the actual problem, we need find the optimal solution or approximate optimal solution of M, so the parameters set of the actual problem is M, use integer programming to generate initial population, choose 10 as the size of initial population

Step 2: define fitness function, we select face gender recognition method proposed in this paper which make M as input parameter and recognition rate as output parameter as fitness function

Step 3: use optimal individual preservation method to select individuals, arithmetic crossover to recombine individuals and non uniform mutation method to preserve diversity in the population

Step 4: set mutation rate, we choose 0.1 as mutation rate to avoid premature convergence

Step 5: evaluate offspring, we select excellent individuals, discard bad individuals and preserve excellent individuals as parents in next iteration

Step 6: judge ending condition, stop if condition is satisfied, else go to step 2. According to many times of experiments, choose 25 as the number of iteration is suitable for our method.

Experimental Results

We select FERET face database as simulation data which is a standard dataset used for face gender recognition. The FERET database which is shown in Fig.1 includes multi-pose and multi-illumination images of person. Before the experiments, we prune training images and testing images into the size of 80*80, and then normalize the gray value of them into 0 to 1.

Fig. 1. Some face images in FERET database

GA optimization trace of the new method is shown in Fig. 2. The horizontal axis represents the number of iteration of algorithm, and the vertical axis represents recognition rate of the new method. The figure shows that the trace is steady after 10 iterations, so selecting 25 iterations as ending condition is suitable for our method. Add up the recognition results which are shown in Table 1. The results illustrate that the new method has higher recognition rate. Compared with PCA and LDA, accuracy of the new method has been improved substantially.

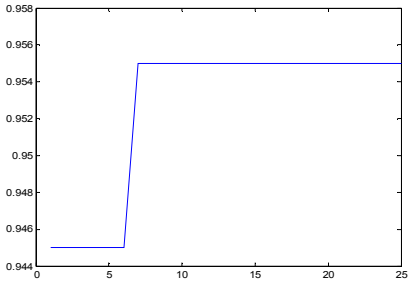

Fig. 2. GA optimization trace of the new method

Table 1. Results of gender recognition rate

A.	R.
PCA	75.5%
LDA	81%
CS+GA	95.5%

Conclusion

Aiming at low recognition accuracy of face gender recognition method currently, we proposed an adaptive recognition method. The new method gain low frequency information of original signal via multiwavelet transform firstly. Then we used CS to extract feature. Finally, ELM is used to achieve gender recognition. To achieve the purpose of adaptive recognition, the new method ensures the value of M according to integer programming GA to achieve the optimal recognition rate. The experimental results tested on a large database showed that the new method can find the value of M with the optimal accuracy adaptively and improved the recognition accuracy substantially compared with traditional methods.

Keywords: PCM/FSK, demodulation, self-adaptive

Abstract. This paper presents a new PCM / FSK digital signal demodulation method. By using an adaptive least mean square error algorithm consider wave single frequency, the tracking signal, analyzes the envelope of the output signal, demodulate the PCM / FSK signal. This paper introduces the basic principles of this demodulation method and implementation process, analyzes the factors that affect the demodulation performance. Simulation results show that this method is superior to the differential demodulation performance, strong anti-jamming capability, ease of software programming and DSP devices achieve a certain value.

Introduction

PCM / FSK telemetry as a current standard system, at home and abroad have a wide range of applications. It transceiver simple, the detection efficiency and spectrum occupancy is more reasonable. With the rapid development of modern digital signal processing methods and computer technology, implemented by software methods for PCM/FSK signal demodulation is not only possible, but also very urgent. [1] proposed a signal-based WD distribution in time-frequency two-dimensional plane of the FSK signal analysis , digital signal resolve to achieve FSK modulation method. [2] proposed a short-term based on the discrete Fourier transform in the frequency domain for the FSK signal analysis , digital signal resolve to achieve FSK modulation method . Both methods of calculation amount than the larger, the signal applied to the inconvenience software demodulation. In recent years, with the rapid rise and development of adaptive signal processing method can consider the use of adaptive signal wave frequency tracking algorithm, the realization of the demodulated signal . This paper presents an adaptive demodulation method is to consider wave LMS adaptive filtering algorithm to track the frequency of the signal based on the information detected by the phase FSK signal demodulation in order to achieve better results.

1 Adaptive consider wave device

Adaptive consider wave is a wave refers to consider the parameters can be updated with adaptive recursive way, it can be divided into the number of adjustable parameters into account wave and adaptive algorithm in two parts.

LMS algorithm is one of the steepest descent method type adaptive algorithm, due to its simple and efficient, easy to implement, is commonly used in adaptive algorithms consider wave. The basic idea of the LMS algorithm is a series of operation by adjusting the parameters, the linear combiner and the error output signal in response to a desired value between the minimum mean square, and the basic block diagram shown in Figure 1.

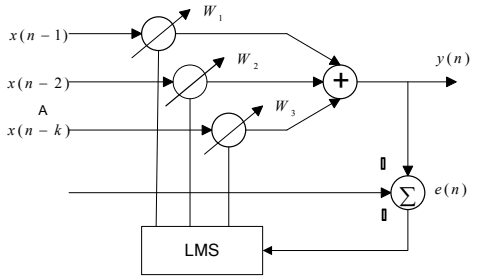

Fig 1 Schematic of adaptive consider wave

The input is $x(n-1), x(n-2), \ldots, x(n-k)$. The output is $y(n)$ weighted linear combination of these inputs, namely:

$$y(n) = \sum_{i=1}^{k} W_i x(n-i) \tag{1}$$

In response, the error signal $d(n)$ representative of the expected:

$$e(n) = d(n) - y(n) \tag{2}$$

According Window and Hoff proposed in 1960 the steepest descent method, the next time the weight coefficient vector A should be:

$$W(n+1) = W(n) + 2\mu e(n)x(n) \tag{3}$$

2 Adaptive demodulation principle

FSK is the continuous phase frequency shift keying, the mathematical expression is:

$$S_{FSK}(t) = A\cos\left[\omega_0 t + \omega_d \int_{-\infty}^{t} f(t)dt + \varphi_0\right] \tag{4}$$

Instantaneous frequency of the FSK signal is:

$$\omega_i = \frac{d}{dt}\left[\omega_0 t + \omega_d \int_{-\infty}^{t} f(t)dt + \varphi_0\right] = \omega_0 \pm \omega_d \tag{5}$$

ASK and FSK signal can be regarded as two signals of different carrier frequencies, the mathematical expression is:

$$S_1(t) = A\cos(\omega_s t + \varphi);\quad S_2(t) = A\cos(\omega_M t + \varphi) \tag{6}$$

With symbols "1" signal corresponding to an example, this time in the form of the signal can be further simplified as:

$$S_2(t) = A\cos\varphi\cos\omega_M t + A\sin\varphi_n \sin\omega_M t \tag{7}$$

Assuming $W_1 = A\cos\varphi, W_2 = A\sin\varphi$,there are:

$$S_2(t) = W_1\cos\omega_M t + W_2\sin\omega_M t \tag{8}$$

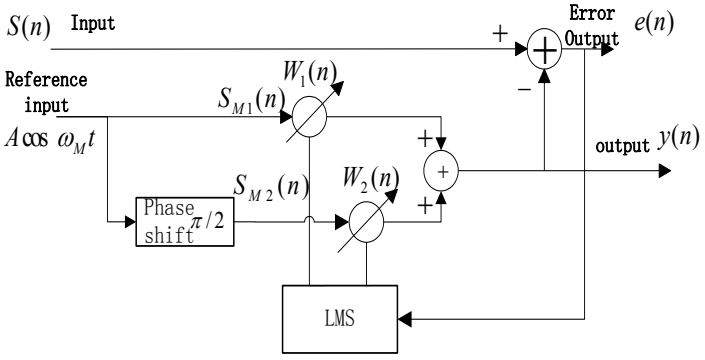

Fig 2 Schematic adaptive demodulation

$$S_{M1}(n) = A\cos\omega_M T_S n$$
$$S_{M2}(n) = A\sin\omega_M T_s n \quad (9)$$
$$y(n) = W_1(n)S_{M1}(n) + W_2(n)S_{M2}(n) \quad (10)$$
$$e(n) = S(n) - y(n) \quad (11)$$
$$W_1(n+1) = W_1(n) + 2\mu e(n)S_{M1}(n) \quad (12)$$
$$W_2(n+1) = W_2(n) + 2\mu e(n)S_{M2}(n) \quad (13)$$

Adaptive implementation process FSK signal is demodulated into account wave: first by the LMS algorithm, tracking mark frequency signal components or space frequency, and then to take into account the output of the absolute value of the wave, and then after removing the median consider wave packet envelope, the envelope waveform of the analysis, the result of demodulation. Taking into account the value of the mathematical expression for the wave:

$$M(n) = \frac{1}{2m+1}\sum_{i=-m}^{m}|y(n+i)| \quad (14)$$

Figure 3 shows a waveform of the demodulated signal at different stages of the process.

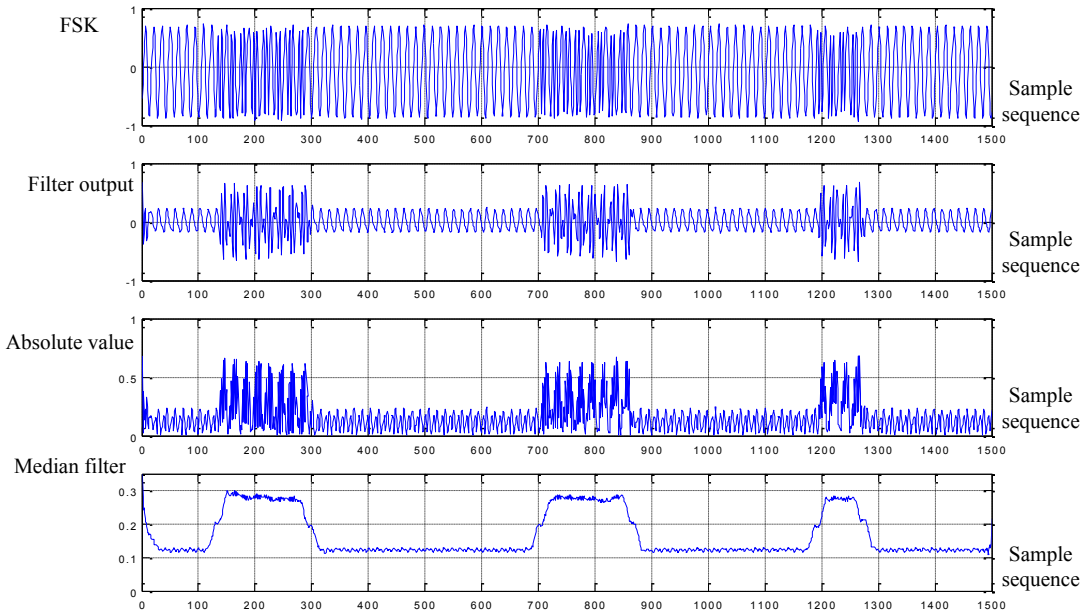

Fig 3 FSK demodulation process adaptive curve

Can be derived from Figure 3, after the absolute value, the value considering the wave, the envelope signal is obtained, then the decision threshold distinguished by the symbol "1" or "0", thereby achieving demodulation of the FSK signal.

3 Performance Analysis

Adaptive consider wave pair FSK signal tracking results will directly affect the outcome of demodulation. LMS adaptive algorithm key is to choose the learning rate parameter. Large learning rate can improve tracking performance oscilloscope into account, but the steady-state performance of the system will be reduced; Conversely, when steady state in order to improve the system performance and the use of small learning rate, the convergence performance will be affected. Therefore, in order to solve the contradiction between convergence rate and steady-state performance, time-varying learning rate can be used.

In the maximum-likelihood ratio criterion derived FSK demodulation method used (non-coherent demodulation) theoretical BER curve, as measured by the theoretical basis for such a demodulation method performance. Since the FSK modulated signal is "1" bit energy, and "0", the correlation coefficient between the energy of the code with a code rate of change varies, the correlation

coefficient will affect the BER, therefore, the code rate corresponds to a different type of BER theoretical curve. In a certain code rate (2Mbps) premise calculate different SNR BER simulation results shown in Figure 4. Visible, adaptive demodulation method is superior performance than non-coherent demodulation performance, especially in the low SNR, demodulation performance is significantly better than non-coherent demodulation.

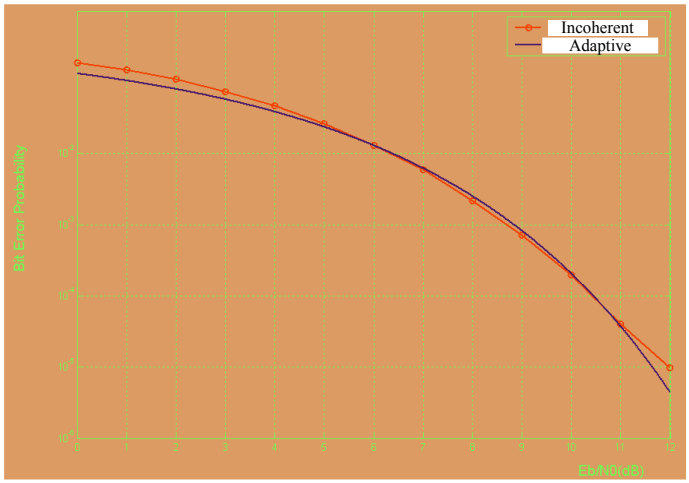

Fig 4 BER curves

Summary

Adaptive consider wave PCM/FSK signal demodulating FSK signal demodulating method is another method. The principle of this method is simple, relatively small amount of computation to facilitate the realization of software programming, suitable for the application of DSP chip to build a software radio system. BER performance and superior anti-interference ability, can effectively suppress the influence of the Doppler frequency of the received signal demodulation.

Keywords: Interpolated Finite Impulse Response; IFIR; RLG; Digital Signal Processing

Abstract. An interpolated finite impulse response (IFIR) digital filter approach was purposed to improve the demerits of traditional finite impulse response (FIR) digital filter in the case of noise attenuation for dithered Ring Laser Gyroscope (RLG). Concentrated on the time delay and computation complexity, a comparison of FIR and IIR digital filter was illustrated. By optimizing the *stretch factor* L, an IFIR digital filter was designed to reach the requirements of a typical RLG. The static experiment results show that the impulse number is decreased from 250 to below 0.15, attenuation of the dither noise is nearly 100 dB and group delay remains the same level by 11.25ms.

Introduction

With dynamic range input, high-reliability, and long working lifespan, Ring Laser Gyroscope (RLG) is widely applied into Strapdown Inertial Navigation System (SINS) , which is utilized for various backgrounds owing to its high-precision and cost-effective performance. The RLGs are dithered to prohibit the effect known as lock-in. However, mechanical dither introduces high frequency noise, which distorts the signal of angular rate from RLGs. By sampling at high rate, a commonly method to remove the noise is applying digital filters.

According to the length of its impulse response sequence, digital filter is classified into the Finite Impulse Response (FIR) digital filter and Infinite Impulse Response (IIR) digital filter. FIR filter enjoys its advantage on the behavior of the strict linear phase response, but acquires higher order to reach the effective performance on magnitude frequency response, which leads to not only an increasing amount of computational operations for two-input adders and multipliers but also an undesirable long time delay. Unlike the linear phase of FIR digital filter, the nonlinearity of IIR filter gives rise to a time delay ripple when the input signal contains different frequencies, which cannot guarantee a real-time output. As a mainstream approach, a lowpass FIR digital filter is designed to remove the dither noise [2], and some methods demonstrate a well-designed cascade of IIR digital filter [3, 4] also satisfy the requirements.

After analyzing of traditional approaches, a method based on Interpolated Finite Impulse Response (IFIR) digital filter is established to demodulate the output signal of dithered RLG. Static experiment results prove that the magnitude response of the filtered signal on the bandwidth of dithered noise is attenuated to 100dB, and it is a compromising solution to ensure the performance on both low group delay and computation complexity reduction.

Filter Analysis

Time delay analysis. There are two types of time delays considering a multi-frequency input signal processed by a digital filter, i.e time delay for operations and group delay. Group delay reflects each component of a broadband signal goes through different phase delays when filtered. For high-order digital filters, time delay for operations is comparative count for little, so the major concern goes to minimize group delay.

For an FIR digital filter which phase function $\theta(\omega_{in})$ is at the frequency ω_{in} of the input signal, the group delay is defined as below

$$\tau_g(\omega_{in}) = -\frac{d\theta(\omega_{in})}{d\omega_{in}} \tag{1}$$

In the case of a linear-phase FIR digital filter, the phase response is given by

$$\theta(\omega_{in}) = -\omega_{in}(N-1)/2 \tag{2}$$

Therefore the group delay

$$\tau_g(\omega_{in}) = -d\theta(\omega_{in})/d\omega_{in} = (N-1)/2 \tag{3}$$

The unit of Eq. 3 is measured by sampling period. Due to the nonlinearity of the phase of an IIR digital filter, which the group delay is variable, the real-time accuracy of RLGs is greatly distorted.

Therefore, the *exclusive* approach to minimize group delay of an FIR digital filter is to reduce the order.

Computation Complexity Analysis. The computation complexity of digital filter structure depends on the sum of two-input adders and multipliers to realize the structure. Table 1 illustrates the computation complexity of N-order of FIR digital filter and IIR digital filter. Under the same requirements of digital filter specifications, FIR digital filters generally load a considerably higher order comparing IIR digital filter, which leads to a heavy workload of computation complexity; the ratio of N_{FIR} / N_{IIR} is always in two-digits.

Table 1. Computation Complexity of N-order FIR and IIR Digital Filter

Digital Filter Structure	Amount of Multipliers	Amount of Two-input Adders
FIR Direct Form	$N+1$	N
FIR Linear Phase	$\left\lfloor \frac{N+2}{2} \right\rfloor$	N
IIR Direct / Cascaded Form	$2N+1$	$2N$

Principle and Design of IFIR Digital Filter

Principle of IFIR Digital Filter. Improvements should be done to solve the dilemma between time delay and computation complexity. The major drawback of FIR digital filter is the heavy computational workload and comparative long time delay on demand of the specification. [6]

As an approach to cut down the workload of traditional FIR digital filter, Interpolated Finite Impulse Response (IFIR) digital filter is an ideal adder-less and multiplier-less solution for filtering output signal of RLGs.

Shown in Fig. 1, the basic structures of bi-stage IFIR digital filter $H_{IFIR}(z)$ comprises of a linear-phase periodic FIR *model filter* $F(z^L)$ and a linear-phase FIR *image-suppressor* $I(z)$. Known as *stretch factor* L, there inserts $L-1$ units of zeros between the prototype samples in the first subfilter $F(z^L)$. As we could expect, a L-fold expansion of time-domain filter impulse response leads to an L-fold shrink in frequency-domain, meaning the transfer function $\widetilde{F}(L\omega)$ in magnitude frequency response is a periodic function with a period of $2\pi / L$. The effect of interpolation sharply shrinks the band edge of transition without employing any adders and multipliers.

The impulse response and magnitude response are shown in Fig. 2 assuming $L = 3$.

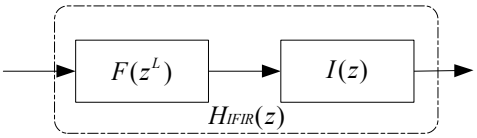

Fig. 1. Structure of $H_{IFIR}(z)$

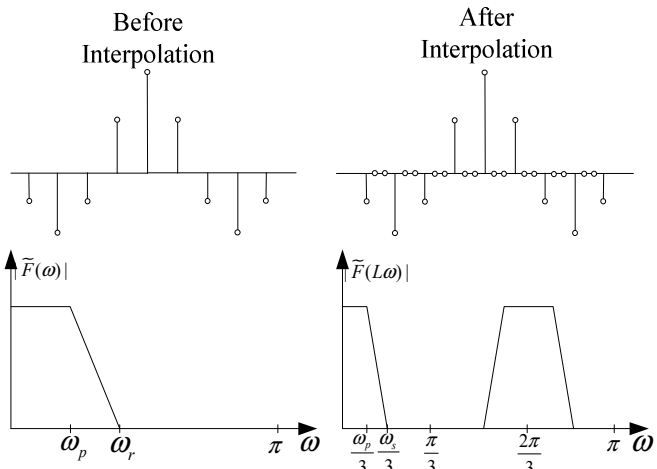

Fig. 2. Impulse Response and Magnitude Response before and after Interpolation

Design of IFIR Digital Filter. A vital step in the development of a digital filter is to determine the specifications given realizable parameters. The frequency domain of output angular rate signal from the typical RLG we focused is below 100Hz, and the high-frequency dithered noise is around 350Hz. Hence, a lowpass digital filter is feasible to attenuate the noise theoretically. According to Nyquist sampling theorem, we set the sampling rate as 4000Hz. To guarantee the efficient of attenuation, the magnitude response of the dither noise should be an order or higher than the one of angular rate [2], i.e the minimum stopband attenuation A_s should be 60dB at least. In the case of this design, specifications of the IFIR digital filter $H_{IFIR}(z)$ are given in Table 2

Table 2. Specifications of the Lowpass IFIR Digital Filter

Passband Edge Freq. ω_s [Hz]	Stopband Edge Freq. ω_p [Hz]	Peak Passband Ripple. A_p [dB]	Minimum Stopband Attenuation. A_s [dB]
100	300	0.01	80

Here, we develop the IFIR digital filter using an *ifir* Matlab function to obtain the coefficients. A standard syntax is written as [H, I, D] = ifir(L, TYPE, F, DEV, STR) where L stands for *stretch factor* and using STR to choose the algorithm level of optimization. Here, we select *advanced* option to fulfill the design. By relying on the well-established the formula of Kaiser for estimating order N of an FIR filter as

$$N = \frac{D(\delta_p, \delta_s)}{\Delta\omega} \tag{4}$$

$$\Delta\omega = \omega_s - \omega_p \tag{5}$$

As illustrated in Table 1, the total multipliers R of the FIR is calculated as

$$\mathrm{R} = \left\lfloor \frac{N+2}{2} \right\rfloor \tag{6}$$

Therefore, the total number of multipliers in the IFIR $\mathrm{R}_{\mathrm{IFIR}}$ can be approximated as

$$\mathrm{R}_{\mathrm{IFIR}} = \frac{D(\frac{\delta_p}{2}, \delta_s)}{\Delta\omega} + \frac{D(\frac{\delta_p}{2}, \delta_s)}{2\pi/\mathrm{L} - \omega_s - \omega_p} = D(\frac{\delta_p}{2}, \delta_s) \cdot f(L) \tag{7}$$

Where

$$f(L) = \frac{1}{\mathrm{L}(\omega_s - \omega_p)} + \frac{1}{2\pi/\mathrm{L} - \omega_s - \omega_p} \tag{8}$$

Assume the derivative function of $df(L)/dL = 0$. It yields

$$L_{optimum} = \frac{2\pi}{\omega_p + \omega_s + \sqrt{2\pi(\omega_s - \omega_p)}} \tag{9}$$

Specifically speaking, after normalizing the desired passband edge and stopband edge respectively to $\omega_p = 0.05\pi$, $\omega_s = 0.15\pi$ and we obtain $L_{optimum} = 3.09$. By adopt $L = 3$ to realize the specifications listed in Table 2, and shown in Fig. 3 here comes the magnitude responses of 82-order linear phase FIR digital filter as the *model filter* and 10-order linear phase digital filter as the *image-suppres*

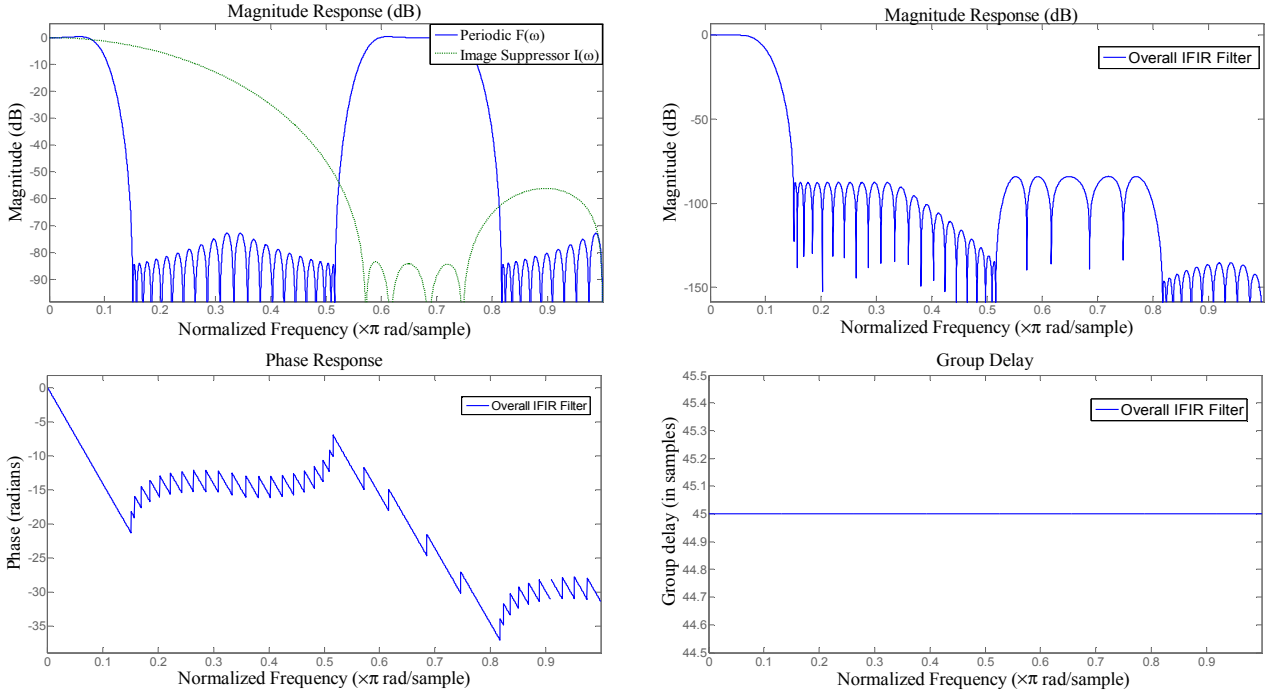

Fig. 3. The Magnitude Responses of $F(z^L)$ and $I(z)$ and the Magnitude Response, Phase Response, Group Delay of the Overall IFIR Digital Filter

Experiments and Test Analysis

To prove the feasibility of the IFIR digital filter, static experiments are implemented. Initially, we design an 81-order lowpass FIR digital filter as a contrast listed as Table 3. Next, set the RLGs IMU on a standard marble platform and keep power-on for 1 hour. Then sample the output signal using an upper IPC by the frequency of 4000 Hz.

Table 3. Specifications of Lowpass IFIR and FIR Digital Filter

Filter Structure	Order N	Passband Edge Freq. ω_s [Hz]	Stopband Edge Freq. ω_p [Hz]	Peak Passband Ripple A_p [dB]	Min. Stopband Attenuation A_s [dB]
Lowpass IFIR	82 & 10	100	300	0.01	80
Lowpass FIR	81	100	300	0.01	80

As shown in Fig. 4, the Power Spectral Density (PSD) and impulse numbers of output signal of designed filters are comparing with input signal before filtered. The impulse number results indicate that IFIR filtered signal acts a similar efficient noise-removal performance as FIR by reducing the impulse number from 250 to below 0.15. From the aspect of PSD, the IFIR filtered signal realizes the purpose of attenuating the dither noise by nearly 100 dB.

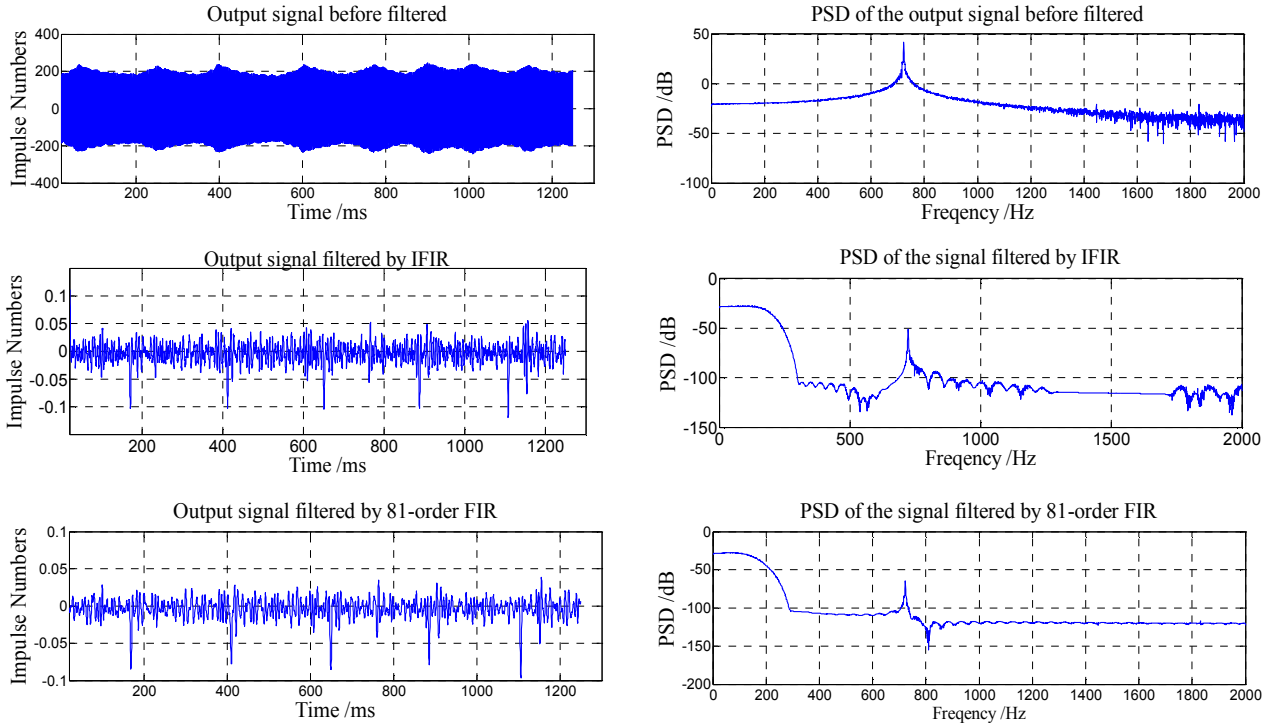

Fig. 4. The Magnitude Responses of $F(z^L)$ and $I(z)$ and The Magnitude Response, Phase Response, Group Delay of the Overall IFIR Digital Filter

As shown in Table 4, in contrast of FIR, the computation complexity of IFIR approach is reduced by around 54% and group delay almost remains the same by 11.25ms.

Table 4. Group Delay and Computation Complexity of IFIR and FIR Digital Filter

Filter Structure	Group Delay [ms]	Computation Complexity	
		Multipliers	Adders
Lowpass IFIR	11.25	38	36
Lowpass FIR	10.125	82	81

Conclusion

An IFIR digital filter is designed to solve the dilemma between time delay and computational complexity to eliminate dither noise of RLGs. In contrast of the previous FIR method, the static experiment results show IFIR digital filter has a cost-efficient performance: the computational complexity is decreased by 54% and group delay stays in the same level by 11.25ms.

Keywords: Call Data Records, Churn Prediction, Telecommunication, Influence Analysis

Abstract. Predicting customer churn is of paramount importance in telecommunication companies. The taxonomy of churn reports that, not only individual constraints but also social factors can create users' propensity to churn. This study uses real world call data records (CDR) to extract the social relationships among mobile phone users and build a multi relational social network, where the influence of users diffuses. The research is conducted to propose a framework that enhances the actionable value of social influence of predicted churners and to examine the parameters that control the churn information diffusion in the telecommunication networks.

Introduction

Nowadays, every business employs customer retention strategies in order to gain competitive advantage and ultimately to survive in a saturated and fiercely competitive environment. Behavioral science is the path that many businesses have adopted as the best lever of retention to yield advantages [1,2,3]. The focus is on understanding the customer attitude and interactions with the organization. Thus, it consists of predicting or describing a particular subscriber's future events based on his or her historical data [4,5,6]. *Customer Churn* prediction is the detection of customers with high propensity to leave the service in the near future. It is the utmost concern of mobile telecommunication operators, as they register more than 30% of annual churn rate. The principle of customer churn prediction is to build a general and simplified process that will classify the subscriber as either churner or non-churner. There are numerous researches on data mining (DM) that study the prediction of churn. A typical DM model for churn prediction includes: The identification of most suitable data for the business task; the data semantics or data preprocessing; the feature selection and building; the model development using DM methods; such as: support vector machine (SVM), neural networks (NN), logistic regression (LR), etc. A validation of the results is required before implementation [6,7,8,9]. Social influence of users has recently been introduced to the research of churn prediction to resolve some limitations of traditional predictive models. Some obvious relevant shortcomings are that: They do not provide an adequate time frame between the detection time and the moment when retention campaign can be successfully deployed. It is necessary to notice that, sufficient long forecast horizon is an advantage; since the further away the customer is from making the decision to churn, the easier it is to retain him at a significantly low cost. Also, traditional churn prediction models do not provide any information about the influence that a user can receive from other users. When people are socially connected, they can imitate behaviors that are not related to their individual patterns [9,10,11], but that are based on the influence they receive from their friends.

In this research, we use call data records or CDR, that are the characteristics of calling traffic (caller receiver IDs, date, duration etc…); to propose a framework research and conduct some experiments on the churn influence diffusion in a multi relational social network. The model is constructed based on different behaviors observed on users' interactions. We are motivated by the fact that: The number of retained or left potential churners can create an impact on the network. We also consider that the diffusion of churn influence should not only consider the growing number of churners but also the structure of the affinities linking users. To the best of our knowledge this

research is one of the first to consider a heterogeneous behavior to build a communication network based CDR.

Research Framework and Description

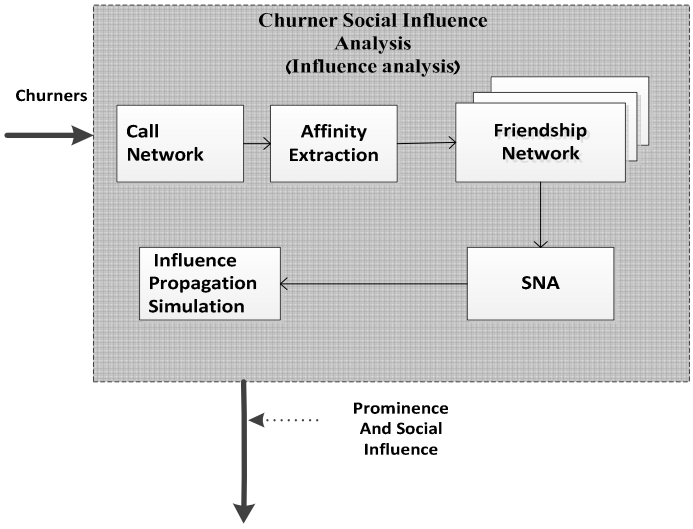

Fig.1 Churner Social Influence Analysis Framework

A call network or call graph is considered as a directed weighted graph $G = (V, E)$, where V is a set of vertices representing individual subscribers, and E is the set of directed edges representing interactive calls among the subscribers. A pairwise is formed for every two subscribers' IDs, where reciprocal calls are registered. Multiple calls between one pairwise constitute the same edge or relationship. Affinities hidden in a single relationship between 2 nodes of a pairwise are extracted using an edges clustering method. The attributes of the edges are constructed based on the call characteristics. Attributes are built targeting particular affinity behaviors. Social network analysis is performed on the multi relation call network obtained whereby churners' influence diffuses based on a diffusion model.

Datasets

The dataset used in this study represents CDR of more than 9 thousand users of one of the main telecom companies in China. It expands a whole month chronological communications of the selected subscribers, all belonging to the city area of Wuhan-Hubei Province. The data contains all the details of the communication (IDs of caller and of receiver, period of call , duration, start time and end time.); the data does not include SMS communication. Content of communication and user real ID where protected as the work where done with the collaboration of the data provider.

Table 1. Data statistics

Total number of valuable calls traffic	303257
Total number of nodes from the local network	9752

Total number of mutual correspondents (count how many numbers call both users)

Experiment and Results

Fig.2 represents the social network obtained with the nodes of our mobile telecommunication network. Fig.3 is the node distribution of the network. The network is scale free and the degree distribution follows the power law. The diffusion of churn information can be modelled in our network, where highly connected subscribers that are churners or for whom churners are close friends, are expected to convey the churn influence. Fig.4 represents the clusterring results based on the attributes in Table 4, showing different behaviors patterns in the communications of the subscribers.

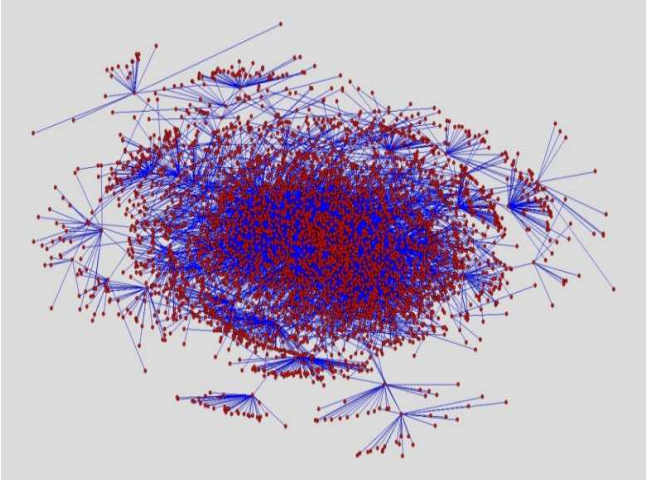

Fig. 2 Call Network

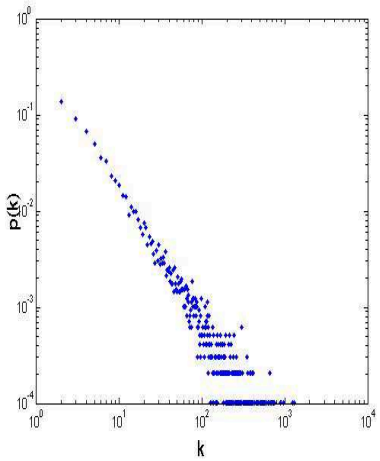

Fig. 3 Node Degree Distribution

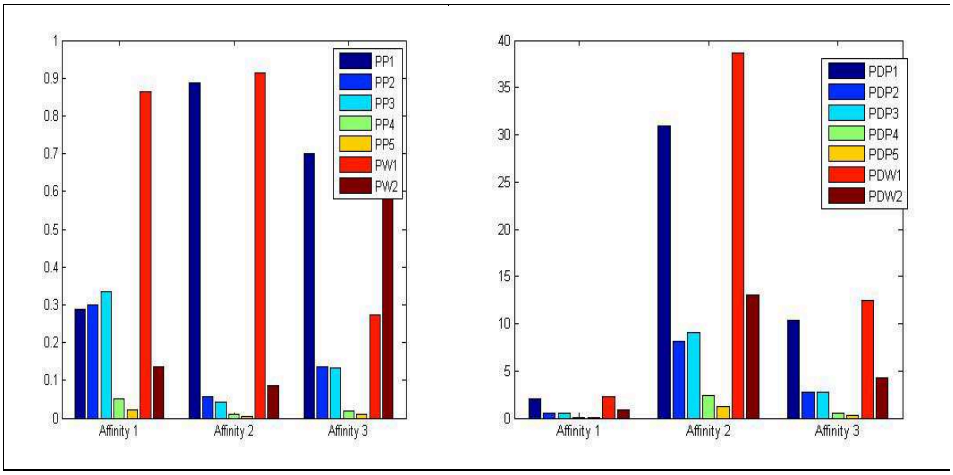

Fig. 4 Affinities Extraction based Edges Clustering: Call Frequency (L) and Call Duration (R)

Influence Diffusion

We use the linear threshold model (LT) in this study to analyze the diffusion of churn information in the different affinity networks. More details on the LT model can be found in [12,13]. Each edge $(u, v) \in E$ has a weight $\omega_{uv} \geq 0$, indicating the power of u influencing v. For convenience, we set for each $(u, v) \notin E$, $\omega_{uv} = 0$; and for each $v \in E$, we have:

$$\sum_{u \in V} w_{uv} \leq 1 \; ; \tag{1}$$

$$\sum_{u \in S_{t-1}} w_{uv} \geq \theta_v \; , \tag{2}$$

where $S_{t-1} \subseteq V$ is the seed set at the time $t-1$ with $S_0 = S$, $\sum_u w_{uv} \in [0,1]$ and $\theta_v \in_R [0,1]$
The weight of the ties is obtained by computing the characteristics of the calls between 2 nodes and the Jaccard coefficient of the similarity in their contacts.

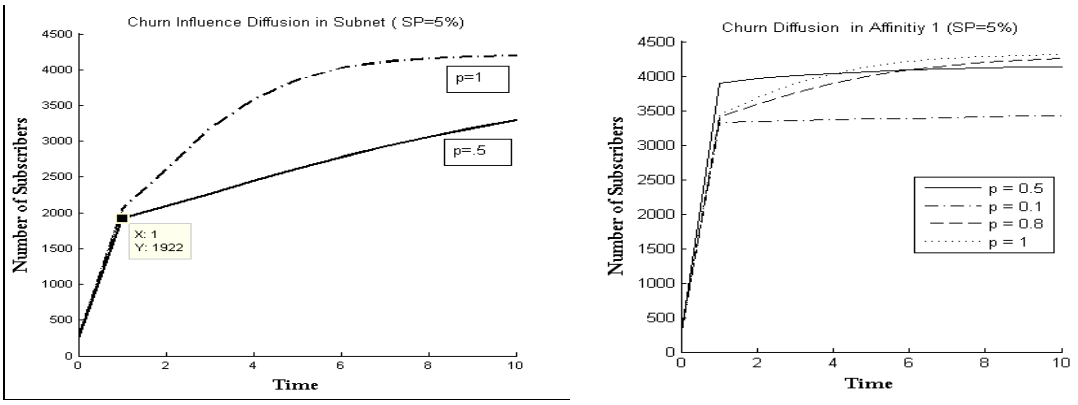

Fig. 5 Churn Diffusion in: Random network (Left) and Affinity Network(Right)

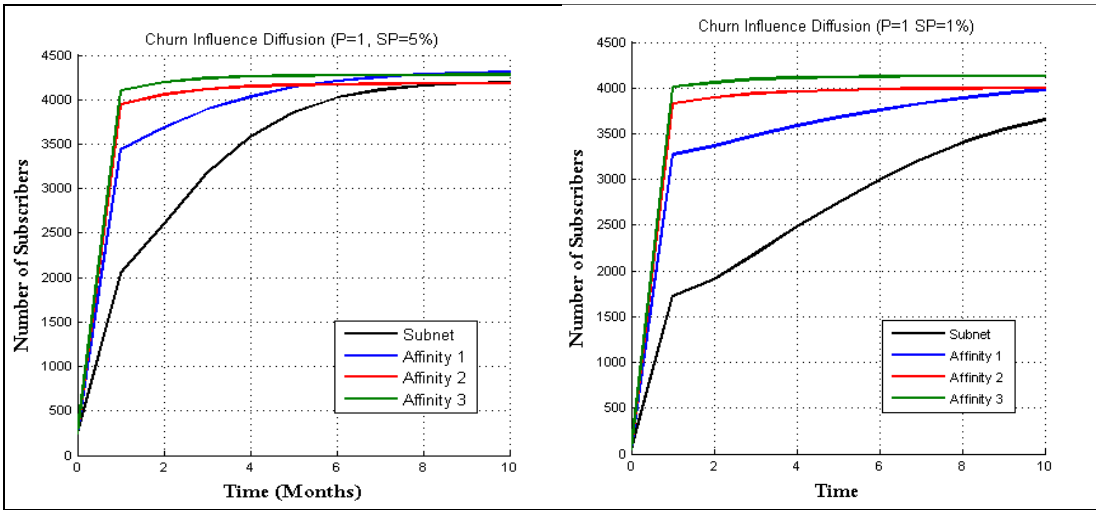

Fig. 6 State of diffusion with initial number of churners (5% and 1% spreaders)

Discussion and Conclusion

Churn happens when the telecom company loses an inherent customer. Based on social evaluation, a subscriber who has many contacts that have churned is expected to have a high propensity to also churn [11]. Current researches on that realm propose that the tie strength should be enhanced and the diffusion should be analyzed to better target churners with long forecast and introduce targeted incentives and applications [14]. We have extracted 3 different users communication behaviors based on the input data sets and have obtained a multi relational call network. All the subscribers of the networks exhibit one or all the behaviors targeted in our clustering methods. Therefore, the obtained tie structure between any two nodes reflects a particular influence weight that is based on the affinity and the similarity between the two nodes. The number of potential future churners increases faster after the first period of the diffusion. This increase is more important in a network where affinities are represented, than in a random network. This means that connectivity plays an ambiguous role in the diffusion of churn influence. This result is consistent with the online social networks. When churn diffuses over a particular behavior group, there is a good probability that most actors will be exposed as churn easily expands in a close community than in a random network (Fig 5, and Fig. 6). Churners that belong to communities represent a risk to the network. The number of initial churners (SP), the probability of transmission (p) and the affinity shared by users all co-contribute to evaluate the true influence received by the future churners. Our proposed framework can be integrated in the overall hybrid churn prediction model which would combine DM and social network analysis for a better accuracy. This

methodology will also provide a better manoeuver on the time aspect for the implementation of retention campaigns.

Keywords: Average gradient angle, image preprocessing, robust dissimilarity, face recognition.

Abstract. In order to obtain more robust face recognition results, the paper proposes an image preprocessing method based on average gradient angle (AGA). It is based on the fact that the central pixel and its neighbors are similar in the local window of an image. AGA firstly calculates the ratio between the relative intensity differences of a current pixel against its neighbors and the number of its neighbors, then employs the arctangent function on the ratio. The dimensionality of the AGA image is reduced by linear discriminant analysis to yield a low-dimensional feature vector. Experimental results show that the proposed method achieves more robust results in comparison with state-of-the-art methods in AR face database.

Introduction

Various methods have been proposed for facial feature extraction and classification, among which the representatives include subspace learning methods, local binary pattern (LBP) methods, Gabor feature based classification methods, preprocessing based approaches[1,2,3,4,5]. While most of these methods in controlled conditions has already achieved impressive performance over large-scale galleries, there still exist many challenges for face recognition in uncontrolled environments. This paper focuses mainly on the image preprocessing technology, and the issue of robustness to facial expression varying, lighting variations and partial occlusions. Zhang et al. develop a novel technique called Gradientfaces (GF) by extracting the illumination insensitive measure from the gradient domain. Wang et al. use a similar idea in the Self Quotient Image. Gross and Brajovic (GB) developed an anisotropic smoothing method that relies on the iterative estimation of a blurred version of the original image. More recently, Xiaoyang Tan and Bill Triggs (TT) present a simple and efficient preprocessing chain that eliminates most of the effects of changing illumination while still preserving the essential appearance details that are needed for recognition, and B. Wang et al. present a novel Illumination normalization technique called weberfaces(WF) by using weber's law. In order to get robustness to facial expression varying, lighting variations and partial occlusions, in this paper, we propose an image preprocessing method based on AGA. It is based on the fact that the central pixel and its neighbors are similar in the local window of an image. AGA firstly calculates the ratio between two terms: One is the relative intensity differences of a current pixel against its neighbors, the other is the number of its neighbors, then employs the arctangent function on the ratio. AGA captures the orientation information for each pixel of an image and finally generates an AGA image which achieves a more robust image dissimilarity between images. The dimensionality of the AGA image is reduced by linear discriminant analysis to yield a low-dimensional feature vector. Experimental results show that AGA achieves more robust results in comparison with state-of-the-art methods in AR face database.

Image preprocessing method based on AGA

Consider a set of images $\{\Gamma_i\}, \Gamma_i \in \Re^{h\times w}, i = 1,2...,n$. At each pixel location, we estimate its AGA. We denote by $\{\alpha_{st}\}, \alpha_{st} \in [0,255], s = 1,2,...,h; t = 1,2,...,w$ the pixel in the two-dimensional image Γ. We denote by $\{\Psi_i\}, \Psi_i \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right)^{h\times w}, i = 1,2...,n$ the set of gradient images, and by $\{\beta_{st}\}, \beta_{st} \in \left(-\frac{\pi}{2}, \frac{\pi}{2}\right), s = 1,2,...,h; t = 1,2,...,w$ the image local approximate gradient in the gradient image Ψ.

Definition 1. Neighbor pixels. We denote by $\Omega=\{b_1,b_2,...b_l\},l=\#(\Omega)$ the neighbor pixels of α. Ω is a collection of the pixels of the surrounding α in the two-dimensional image.

Definition 2. AGA. We denote by β the image average gradient angle of α. β reflects the average gradient angle between α in Ω. The formula is as follows:

$$\beta=\arctan\left(\frac{1}{l}\left(\sum_{m=1}^{l}b_m-\alpha\right)\right),\quad \Omega=\{b_1,b_2,...b_l\},l=\#(\Omega) \tag{1}$$

Expressed in Eq (1) is only an approximation of the average gradient angle. Substantially, it is reasonable to consider a gradient. Usually, the pixel values of the local region in the image tend to be relatively close. For dramatic change of the local area pixels, it often implies the emergence of contour. The contour may be the general contour of the image (such as the face, mouth, eyes, nose, etc.), and may also be caused by outlier pixel (such as sunglasses, scarf). Through the calculation of the gradient values, on the one hand the local image similarity is retained, on the other hand, the outline of the image information is also retained. In the following, we will compare the difference dissimilarity between the pixel intensity values and the local approximate gradient values by different distance metric. Let x_j be the *p*-dimensional column vector obtained by writing image Γ_j in lexicographic ordering. The same is to let y_j be the *p*-dimensional column vector obtained by writing image Ψ_j in lexicographic ordering. where the pixel values of the corresponding images Γ_j,Γ_q are represented in the range $[0,1]$. The local approximate gradient values of the corresponding images Ψ_j,Ψ_q are represented in the range $(-\pi/2,\pi/2)$.

Let us consider a motivating example in which different dissimilarity measures are applied to the images shown in Fig. 1. In Fig.1, the resolution of all images resolution is adjusted to 128×128 ,and the pixel neighbor layer is set to 2. As can be seen in Table 1, the pixel intensity values associates a smaller distance between the original image and an image from a different subject. The distance between the original and the same image with occlusion is larger. In contrast, the use of the AGA values results in a large distance between the original image and the image of a different person.

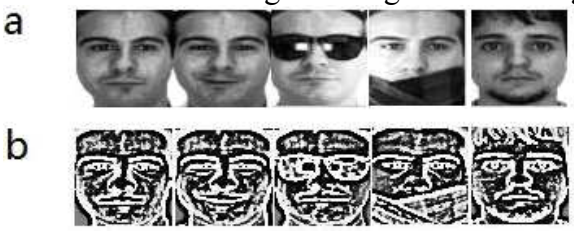

Fig. 1 Images used for the dissimilarity measurement. (a)Original images (b) AGA images. Each row from left to right in turn is the neural expression, smiling expression, occluded (sunglasses), occluded (scarves) and another person's neural expression.

Table 1 Dissimilarity comparison between neural image and the other images with different measures

	Euclidean		Cosine	
	Intensity	AGA	Intensity	AGA
Neural-Smile	0.14	1.02	0.09	0.55
Neural-Sunglasses	0.51	1.09	0.54	0.70
Neural-Scarves	0.39	1.14	0.78	0.62
Neural-Different person	0.32	**1.28**	0.39	**0.85**

Assume that we are given an images Γ ,we can obtain its AGA images Ψ by calculating AGA value. Let y be the p-dimensional column vector obtained by writing Ψ in lexicographic ordering. The dimensionality of the p-dimensional column vector is reduced by LDA to yield a low-dimensional feature vector.

Linear Discriminant Analysis

Linear Discriminant Analysis (LDA) searches for those vectors in the underlying space that best discriminate among classes (rather than those that best describe the data). More formally, given a number of independent features relative to which the data is described, LDA creates a linear combination of these which yields the largest mean differences between the desired classes. Mathematically speaking, for all the samples of all classes, we define two measures: 1) one is called within-class scatter matrix, as given by

$$S_w = \sum_{c=1}^{C} \sum_{h=1}^{l^c} (y_h^c - m^c)(y_h^c - m^c)^T \tag{2}$$

where y_h^c denotes the hth training sample in class c, l^c is the number of training samples in class c, m^c is the mean of the training samples in class c, and C is the number of class. 2) the other is called between-class scatter matrix

$$S_b = \sum_{c=1}^{C} l^c (m^c - m)(m^c - m)^T \tag{3}$$

where m represents the mean of all classes.

The goal is to maximize the between-class measure while minimizing the within-class measure. The discriminative projection basis W and eigenvalues Λ are obtained by solving the thin Linear Discriminant Analysis(LDA) eigendecomposition:

$$(S_w + \varepsilon I)^{-1} S_b W = W\Lambda \tag{4}$$

where ε is a small regularization constant (10^{-3} below) and I is the identity matrix. Thus, the original p-dimensional space is projected onto a final d-dimensional space using LDA.

Experiments

In this section we evaluate the robustness of our method for the application on face recognition. A publicly available face databases, namely, AR [6] is used for experimental evaluation. The AR database consists of more than 4,000 frontal view face images of 126 subjects. Each subject has up to 26 images taken in two sessions. The first session contains 13 images, numbered from 1 to 13, including different facial expressions(1-4), illumination changes (5-7), and different occlusions under different illumination changes (8-13). The second session duplicates the first session two weeks later. Fig. 2 shows a sample of images used in our experiments. For AR, we resize them to 128×128. To verify the effectiveness of the proposed method, in this series of experiments we evaluate the performance of the proposed method and compare it to that of several methods using the LDA and 1-NN classifier.

Fig. 2 Face images of the same subject taken from the AR database.

We investigate the robustness of our scheme for the case of facial expression varying, illumination variations, occlusions(sunglasses)-illumination changes, and occlusions(scarves)-illumination changes. Table2 provides the detailed information of each experiment. The best recognition rates are shown in Table 3. From Exp.1 to Exp.4, we use images 1-4 of session 1 for training. As our results show, AGA-LDA achieves better recognition rate compared with other methods. AGA-LDA achieves approximately 93.27% recognition rate for different expressions(Exp.1). For Exp.2, AGA-LDA achieves approximately 89.45% recognition rate for the case of illumination changes. For Exp.3 and

Exp.4, which are more difficult experiment on the AR database, AGA-LDA achieves approximately 68% recognition rate for the case of occlusions(sunglasses)-illumination changes, and achieves approximately 67.45% recognition rate for the case of occlusions(scarves)-illumination changes.

Table 2 The detailed information of different experiments

Exp.	Training Set (session 1)	Test Set (session 2)
Exp.1	1-4	1-4 expressions(neural, smile , anger and scream)
Exp.2	1-4	5-7 illumination variations
Exp.3	1-4	8-10 sunglasses-illumination
Exp.4	1-4	11-13 scarves-illumination

Table 3 Best recognition rate comparison on different experiments

Method	Exp.1	Exp.2	Exp.3	Exp.4
LDA	88%	51.33%	16%	34%
GF-LDA	88.25%	82%	39%	45.33
GB-LDA	61.5%	52.33%	20.33%	36.33%
MSR-LDA	71.75%	68.3%	12%	27%
TT-LDA	76.25%	73.67%	25.67%	50%
WF-LDA	68.5%	62.67%	31.67%	35.67%
AGA-LDA	**93.27%**	**89.45%**	**68%**	**67.45%**

Conclusions

In this paper, we propose an image preprocessing method based on AGA. AGA captures the average gradient angle for each pixel of an image and finally generates an AGA image which achieves a more robust image dissimilarity between images. The dimensionality of the AGA image is reduced by linear discriminant analysis to yield a low-dimensional feature vector. Our experiments show that the proposed method is robust.

Keywords: Kirsch masks filter, direction image, decision level fusion, linear discriminant analysis, face recognition.

Abstract. In this paper, a feature representation method based on Kirsch masks filter for face recognition is proposed. We firstly obtain eight direction images by performing Kirsch masks filter. For each direction image, the low-dimensional feature vector is computed by Linear Discriminant Analysisis. Then, a fusion strategy is used to combine different direction image according to their respective salience. Experimental results show that our methods significantly outperform popular methods such as Gabor features, Local Binary Patterns, Regularized Robust Coding (RRC), and achieve state-of-the-art performance for difficult problems such as illumination and occlusion-robust face recognition.

Introduction

Face recognition (FR) has received a great deal of attention from the scientific and industrial communities over the last three decades due to its wide range of applications in entertainment, smart cards, information security, law enforcement, access control and video surveillance. Various methods have been proposed for facial feature extraction and classification, among which the representatives include subspace learning methods [1], [2], local binary pattern (LBP) methods [3], Gabor feature based classification methods [4], the recently developed sparse representation based methods [5], and the like. While most of these methods in controlled conditions has already achieved impressive performance over large-scale galleries, there still exist many challenges for face recognition in uncontrolled environments. In this paper, we propose a feature representation method based on Kirsch masks filter for face recognition(abbreviated as FRKMF). Given a face image, for each pixel we compute its eight direction information by performing Kirsch masks filter operator. We can obtain eight direction images. LDA is performed to extract the corresponding low-dimensional features. A fusion strategy is used to combine different images according to their respective salience. The experimental results show that the proposed method significantly improves recognition performance under partial occlusions, varying illuminations.

Kirsch Masks Filter

For an input image, we can calculate eight directional edge response value of a particular pixel using Kirsch masks in eight different orientations (M0~M7) centered on its own position. These masks are shown in the Fig. 1. Applying eight masks, we obtain eight edge response value m0, m1, …, m7, each representing the edge significance in its respective direction. The presence of corner or edge show high response values in particular directions. By performing Kirsch masks filter, an input image is decomposed into eight direction images.

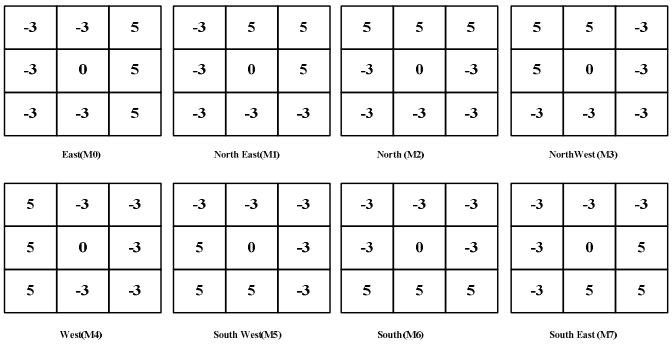

Fig. 1 Kirsch edge response masks in eight directions.

Linear Discriminant Analysis

Linear Discriminant Analysis (LDA) searches for those vectors in the underlying space that best discriminate among classes (rather than those that best describe the data). More formally, given a number of independent features relative to which the data is described, LDA creates a linear combination of these which yields the largest mean differences between the desired classes. Mathematically speaking, for all the samples of all classes, we define two measures: 1) one is called within-class scatter matrix, as given by

$$S_w = \sum_{c=1}^{C} \sum_{h=1}^{l^c} (\xi_h^{\ c} - m^c)(\xi_h^{\ c} - m^c)^T \tag{1}$$

where $\xi_h^{\ c}$ denotes the hth training sample in class c, l^c is the number of training samples in class c, m^c is the mean of the training samples in class c, and C is the number of class. 2) the other is called between-class scatter matrix

$$S_b = \sum_{c=1}^{C} l^c (m^c - m)(m^c - m)^T \tag{2}$$

where m represents the mean of all classes.

The goal is to maximize the between-class measure while minimizing the within-class measure. The discriminative projection basis W and eigenvalues Λ are obtained by solving the thin Linear Discriminant Analysis(LDA) eigendecomposition:

$$(S_w + \varepsilon I)^{-1} S_b W = W\Lambda \tag{3}$$

where ε is a small regularization constant (10^{-3} below) and I is the identity matrix. Thus, the original D-dimensional space is projected onto a final d-dimensional space using LDA.

Multiple Direction Images Fusion

Assume that we are given a sample $F \in \Re^{M \times N}$. We can obtain eight direction images Φ^s by performing Kirsch masks filter. Let x^s ($s = 1,..,8$) be the D-dimensional vector obtained by writing images Φ^s in lexicographic ordering. We can compute the average feature vector $\overline{y^{s,c}}$ of the cth person of the sth training sample set.

$$\overline{y^{s,c}} = \frac{1}{l^c} \sum_{j=1}^{l^c} W^T x_j^{s,c}, \quad c = 1,2,...C \tag{4}$$

where $x_j^{s,c}$ is jth training sample of the cth person of the sth training sample set. Then, we compute the average cosine distance $\overline{d^{s,c}}$ between $\overline{y^{s,c}}$ and $\overline{y^{s,j}}$ ($j = 1,2,...C$).

$$\overline{d^{s,c}} = \frac{1}{C}\sum_{j=1}^{C}\left(1 - \frac{(\overline{y^{s,c}})^T \overline{y^{s,j}}}{\left\|\overline{y^{s,c}}\right\|\left\|\overline{y^{s,j}}\right\|}\right) \tag{5}$$

For the *c*th person, we obtain s between-class distances which are sorted according to descending order. Each $\overline{d^{s,c}}$ characterizes the weighted coefficient of the *s*th gradient orientation feature of the *c*th person. Given a test image $F_{test} \in \Re^{M\times N}$, We can compute the corresponding eight orientation images Φ_{test}^{s}. Let x_{test}^{s} ($s = 1,..,8$) be the *D*-dimensional vector obtained by writing images Φ_{test}^{s} in lexicographic ordering. We can compute the *d*-dimensional vector $y_{test}^{s} = W^T x^s$ using LDA. The projected feature vectors y_{test}^{s} are classified using the nearest neighbor rule and the cosine "distance"

$$d^{s,c}(y_{test}^{s}, \overline{y^{s,c}}) = 1 - \frac{(y_{test}^{s})^T \overline{y^{s,c}}}{\left\|y_{test}^{s}\right\|\left\|\overline{y^{s,c}}\right\|} \tag{6}$$

When a face image is presented to the system, its eight direction images are computed, separately projected into their optimal discriminant spaces and used to compute the corresponding distance scores. Each score is normalized using the "*z-score*" method

$$z^{s,c} = \frac{d^{s,c} - \mu^{s,c}}{\sigma^{s,c}} \tag{7}$$

where $\mu^{s,c}$, $\sigma^{s,c}$ are, respectively, the mean and standard deviation of over the training set.

Finally, the eight scores are fused at the decision level. We fuse the eight similarity scores using the simple sum rule, and F_{test} is classified by solving the following optimization problem:

$$k = \arg\min_{c} \sum_{s=1}^{8} (\omega^{s,c}) z^{s,c} \tag{8}$$

where $\omega^{s,c}$ is the weighted coefficient ,and $\omega^{s,c} = \overline{d^{s,c}} \Big/ \sum_{s=1}^{8} \overline{d^{s,c}}$.

Experiments

The AR database [6] consists of more than 4,000 frontal view face images of 126 subjects. Each subject has up to 26 images taken in two sessions. The first session contains 13 images, numbered from 1 to 13, including different facial expressions (1-4), illumination changes (5-7), and different occlusions under different illumination changes (8-13). The second session duplicates the first session two weeks later. To verify the effectiveness of the proposed methods, in this series of experiments we evaluate the performance of the proposed methods and compare them to that of several methods using the simplest nearest neighbor (1-NN) classifier with the cosine distance. For LBP, the χ^2 histogram distance is used. In order to evaluate the performance of our algorithm for the case of synthetic occlusions. A series of similar experiments were also performed. In these experiments, all test images were artificially occluded by a "Dinosaur" patch at random position. We used "Dinosaur" patch of resolution 35×35. For all experiments, we used manually aligned cropped images of resolution 64×64. We carried out the following 3 experiments in AR database. In experiment 1, we used images 1-4 of session 1 for training and images 1-7 of session 2 for testing. In experiment 2, we performed a similar experiment with the experiment 1, and the only difference is that all test images were artificially occluded by a "Dinosaur" patch at random position. In experiment 3, we used images 1-4 of session 1 for training and images 8-13 of session 2 for testing. Fig. 2 shows a sample of images used in our experiments. Table 1 tabulates the best recognition rates of different methods about experiment 1,2 and 3. As shown in Table 1, the proposed FRKMF consistently outperform the other compared methods. As we can see, for the non-occluded facial experiment (experiment 1), FRKMF performed the best. For experiment 2 and 3, which are the most difficult experiments on the AR database, FRKMF largely outperformed all other methods. More specifically, the gain in recognition accuracy goes up to 5.58 and 7 percent on artificial occlusions and original occlusions. In contrast to experiments 1, these results are statistically significant.

Fig. 2 Face images of the same subject taken from the AR database.

Table 1 Recognition Rates on the AR Database for Experiment 1, Experiment 2, and Experiment 3

Methods	**Exper.1**	**Exper.2**	**Exper.3**
PCA	54.86%	25.85%	14.17%
LDA	69.57%	21.00%	25.83%
Gabor-PCA	66.43%	43.00%	14.83%
Gabor-LDA	86.14%	22.57%	45.67%
LBP-8	95.14%	84.71%	78.00%
RRC-L_1	75.57%	58.57%	39.5%
FRKMF	**96%**	**90.29%**	**85%**

Conclusions

We propose a feature representation method based on Kirsch masks filter for face recognition. Given a face image, we firstly compute its eight direction images by performing Kirsch masks filter operator. For each direction image, the low-dimensional feature vector is computed by Linear Discriminant Analysisis. Then, a fusion strategy is used to combine different direction image according to their respective salience. The experimental results show that the proposed method significantly improves recognition performance under partial occlusions, varying illuminations.

[a] QianLong@yeah.net

Key words: household sub- network; Bluetooth control technology; embedded; universal device control protocol

Abstract. With the development of household appliances, the short of communication among them is more and more becoming a problem. At present there is no central point of control among the traditional home appliances, and we cannot access them through Internet. To solve these issues, home network is proposed to connect all the appliances, home PC and portable devices together using network technology. Controlling all the appliances through one single node(the home network gateway), home network makes life much simpler and convenient. There are several local area network technologies applicable to home network. Bluetooth technology is chosen in this paper as the home networking technology due to its many advantages over others. The implementation scheme of home control sub- network based on Bluetooth serial part profile(SPP) and the standards of Home Network Platform in China is proposed. According to actual application fields, the communication protocol architecture for this scheme is established by using appliance control protocol promoted by the manufacturers and universal device control protocol(UDCP) over SPP. Many management functions of appliance terminals are realized such as appending, login, operation, logout and alarming. Implementation methods of appliance terminal based on an entirely embedded single- chip manner and mobile control terminal which is realized by computer simulation are proposed. Analysis and solution of baud rate error brought by inaccurate crystal frequencies are presented. Further discussion about applying ad hoc technology to home control sub- network is carried out.

Bluetooth

Bluetooth is a wireless technology standard for exchanging data over short distances(using short wavelength UHF radio waves in the ISM band from 2. 4 to 2. 485 GHz) from fixed and mobile devices, and building personal area networks. Invented by telecom vendor Ericsson in 1994, it was originally conceived as a wireless alternative to RS- 232 data cables. It can connect several devices, overcoming problems of synchronization.

Bluetooth is managed by the Bluetooth Special Interest Group(SIG), which has more than 19,000 member companies in the areas of telecommunication, computing, networking, and consumer electronics. Bluetooth was standardized as IEEE 802. 15. 1, but the standard is no longer maintained. The SIG oversees the development of the specification, manages the qualification program, and protects the trademarks. To be marked as a Bluetooth device, it must be qualified to standards defined by the SIG. A network of patents is required to implement the technology, which is licensed only for that qualifying device.

The use of Bluetooth

Bluetooth is a standard wire- replacement communications protocol primarily designed for low consumption, with a short range based on low- cost transceiver microchips in each device. Because the devices use a radio(broadcast) communication systems, they do not have to be in visual line of sight of each other, however a quasi optical wireless path must be viable. Range is power- class-dependent, but effective ranges vary in practice; see the table on the right.

The effective range varies due to propagation conditions, material coverage, production sample variations, antenna configurations and battery conditions. Most Bluetooth applications are in indoor conditions, where attenuation of walls and signal fading due to signal reflections will cause the range to be far lower than the specified line- of- sight ranges of the Bluetooth products. Most Bluetooth applications are battery powered Class 2 devices tends to set the range limit. In some cases the effective range of the data link can be extended when a Class 2 devices is connecting to a Class 1 transceiver with both higher sensitivity and transmission power than a typical Class 2 device. Mostly however the Class 1 devices have a similar sensitivity to Class 2 devices. Connecting two Class 1 devices with both high sensitivity and high power can allow ranges far in excess of the typical 100m, depending on the throughput required by the application. Some such devices allow open field ranges of up to 1 km and beyond between two similar devices without exceeding legal emission limits.

While the Bluetooth Core Specification does mandate minima for range, the range of the technology is application specific and is not limited. Manufacturers may tune their implementations to the range needed for individual use cases.

class	Max. permitted power		Typ. Range
	(mW)	(dBm)	(m)
1	100	20	~100
2	2.5	4	~10
3	1	0	~1

Version	Data rate	Max. application throughput
1.2	1 Mbit/ s	>80 kbit/ s
2.0 + EDR	3 Mbit/ s	>80 kbit/ s
3.0 +HS	24 Mbit/ s	See Version 3.0 + HS
4.0	24 Mbit/ s	See Version 4.0 LE

As a new idea, family network that represents family informatization has already obtained more and more attention by people. Generally speaking, family network is a combination which contains processing, governing, transmitting and storing the information that have the capability to connect and integrate so many devices in one' s family, like calculating, controlling, guarding and communicating. After that, household sub- network is in charge of controlling and governing with the relevant network parts like the family appliance, the energy resources and the security. Because Bluetooth technology has a lot of advantages like lower prime cost, lower consumption, better security, superior transmitting function and flexible network form, it has already become one of the most important wireless technology part to fulfill the family network.

The structure of family network

According to two different types, physical transmitting medium and bottom protocol, when connect devices or gateways, family network can be divided into two different network parts, one is the major family network, the other is household sub- network.

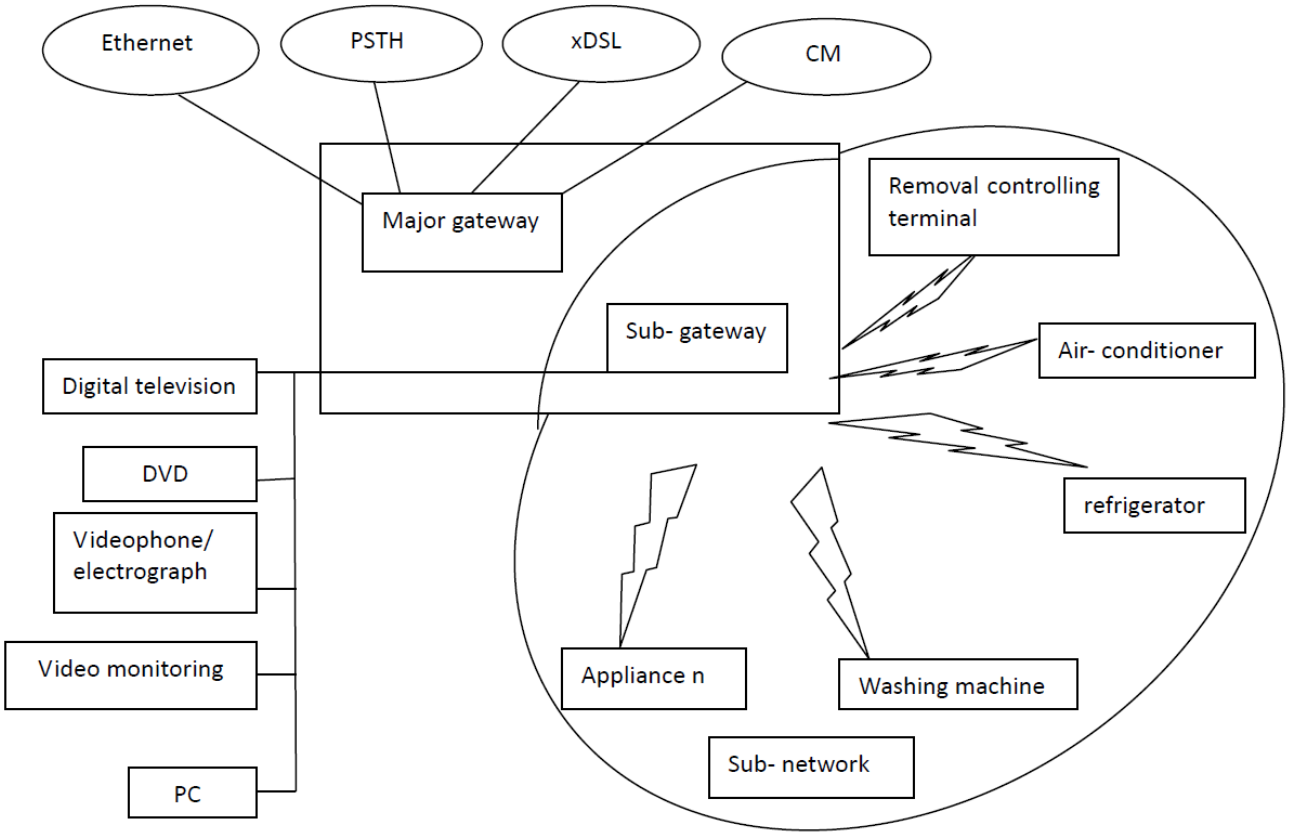

Figure 1. The structure of family network

The major family network is a network part which has the fast information transmitting rate device, including information device, amusement device, communication device, the major family network gateway(major gateway), household sub- network gateway(sub- gateway), etc. Its main function includes providing the communication with all the public network, family intelligent governing and family electrical amusement. The major gateway is a kind of gateway device in the major family network, it can accomplish the communication with the high speed information transmitting device in family network, provide the exterior network joggle to all kinds of insert devices, and as a servicer to be interviewed by the interior devices and exterior network in the meantime. However, household sub- network includes some lower speed devices network parts, like subsidiary gateway, removal controlling terminal, three expression and three prevention devices, information appliance, etc. The subsidiary gateway can accomplish the communication with household controlling sub- network and provide the major network joggle for all kinds of insert devices.

The accomplishment of household controlling sub- network hardware

Household controlling sub- network is composed of three logic substances by subsidiary gateway, removal controlling terminal and IA.

Removal controlling terminal adopts the scheme of flushbonading single chip, connecting with RS232 joggle and Bluetooth module by PC. IAC Application, working on PC, provide the user interface and accomplish UDCP(universal device control protocol), and fulfill the data communication with users and all kinds of sub- network devices by the flushbonading program of Bluetooth receive and dispatch module. Appliance controlling circuit, centralized controlling center, commonly provides by the appliance factories and makes of a mini- processor and a series of number, analogous circuit, in charge of collecting appliance' s all kinds of controlling process and data, and by universal asynchronous receiver transmitter to communicate with Bluetooth receive and dispatch module with 19.2 kbit/ s. Their communication obey the family controlling protocol.

The use of UART joggle completely obey this lower speed scene and allow the appliance manufacturer to use low side mini- processor to reduce prime cost in the process of appliance controlling circuit. Appliance controlling circuit supply electricity together by the source unit of Bluetooth receive and dispatch module. BlueCore2- Exernal cover with 8 MB Flash which consists of the smallest Bluetooth system of the complete flushbonading single chip scheme design. In the process of the actual research, we found that it must pledge both sides to have certain timing precision by using UART joggle to achieve the communication with the appliance controlling circuit and Bluetooth receive and dispatch module. Because the accumulation of timing plus- minus deviation will probably be defeated of serial communication. In general, calculating Baud rate use this formula:

$$B = \frac{f_{osc}}{kN}$$

f is the frequency of crystal oscillator; N is the factor of integer frequency division; k is the times of collecting one information code.

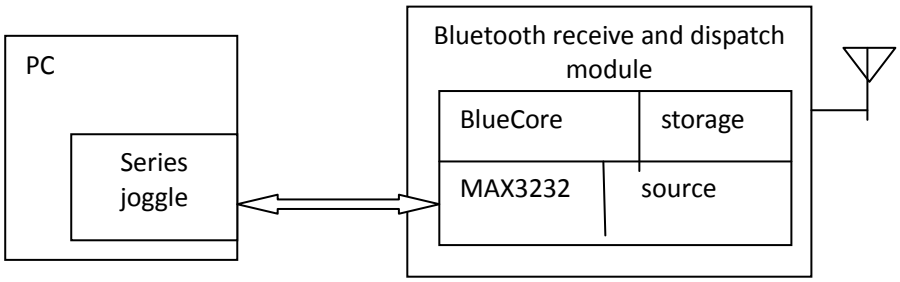

Figure 2. Removal controlling terminal

Conclusion

To use Bluetooth wireless technology, a device has to be able to interpret certain Bluetooth profiles, which are definitions of possible applications and specify general behaviors that Bluetooth enabled devices use to communicate with other Bluetooth devices. These profiles include settings to parameterize and to control the communication from start. Adherence to profiles saves the time for transmitting the parameters a new before the bi- directional link becomes effective. There are a wide range of Bluetooth profiles that describe many different types of applications or use cases for devices.

Keywords: document, archives management, office automation

Abstract. History archives, an important part of archives, records the historical process of social development and objectively reflects the process and outcome of problem-handling, decision-making, construction, research and development. With the development of reform, how to improve the management level of archives to provide the file information timely, accurately and completely to meet the demand and adapt to the new situation of development is a new topic in the archives work. The paper introduces advantages and problem brought by archives management in the environment of office automation, as well as suggestions to develop archives management.

Introduction

History archives, an important part of archives, records the historical process of social development and objectively reflects the process and outcome of problem-handling, decision-making, construction, research and development. With the development of reform, how to improve the management level of archives to provide the file information timely, accurately and completely to meet the demand and adapt to the new situation of development is a new topic in the archives work. Thus automation of files management opens a new chapter for archives work.

Advantages of office automation for archives management

Efficient and convenient filing rate. Powerful information processing ability is the biggest advantage given by computer to office automation. The archives management in the environment of office automation is fully integrated with information technology, maximizes the cumbersome procedures of traditional paper files to a minimum, and does related work of archiving. These advantages can effectively guarantee resource better utilized.

Comprehensively and efficiently realize the sharing of resources. Records management in the environment of office automation can give full play to the role of information technology, effectively implement the system of file management, and realize the resource sharing, reading and searching conveniently and quickly. At the same time, the promotion of the network and information transmission technology make the electronic archives management search, classify, arrange, optimize and filter according to different circumstances, which is conducive to strengthen the archives management and play the role of those advantages, such as high transmission speed, strong use ability and large amount of information. It is also able to share resources. Especially in government organs and institutions, the utilization of information is more comprehensive and efficient.

Storage is more stable. Compared with paper archives, electronic archives can make full use of modern science and technology to store and transmit, such as DVD disk, U disk, mobile hard disk, memory card, and so on. These equipments' advantage is not easy to be affected by object environment, but also has the characteristics of long-time storage, a large amount of information, strong stability. Transferring document resources directly through the network tool make the stability and safety of documents greatly improved.

Archives management in the environment of office automation is simpler. The traditional archival management has a complicated process, from the document information collection, classification, sorting, filing to the end. Each step not only needs a lot of manpower, material resources, but also is easy to make mistake. But in the environment of office automation, the assistance of computer make the complicated work simple and the operation not need too much time and energy, but also improve the quality of document and reduce the time and space.

The main problems existing in office automation of archives management

The security of electronic document becomes vulnerable. The biggest difference between electronic culture and paper file is that electronic culture has no fixed form and is easy to change, without traces even after being modified. However, once paper file is modified, the traces are obvious. Therefore, the confidentiality of electronic documents is not good as paper documents. Because electronic document make some file with high confidentiality become weaker, this is not conductive to safety management of file information. At present, although some related technology can prevent others increase, delete, or change the original forgery, but can not effectively identify original document. Paper draft can pass through the seal or signature. These are severe test electronic culture suffered in security aspect. In anther word, electronic culture's security exist hidden risk.

The quality of archives managers is high. The application of office automation system in archives management needs to strengthen archives personnel's quality. The theory, method and technology related to archive management is not enough, excellent computer technology is necessary. So archives management personnel not only need to reach a certain level of knowledge, but also need to master modern high technology and ability to handle related issues. At present, most archives management personnel are deficient in technology, related theoretical knowledge, and initiative in the use of office automation equipment, which is not conductive to the electronization of archives management.

The network environment of the document information exist security risks. Because the document generates in the computer, transmits and processes through the network, it is vulnerable to multiple threats from the computer and network. On one hand, illegal access on the internet is unquantifiable, the firewall is impossible to guard against the hacker master; on the other hand, internal personnel often unauthorized spread out data of document information management system through the USB flash drive, WIFI tuning demodulator, a smart phone, Bluetooth adapter, digital music player, infrared transmission, e-mail, FTP and other ways. In bad network environment attacked by both inside and outside, the document information cannot insulate itself, and document management always face security risks.

Authenticity identification and maintenance of document information become more difficult. The essential attribute of archives is the original record of the carrier, while the carrier of paper document is inseparable with the external characteristic recorded, such as handwriting, signature, and seal and so on. Electronic document is restricted in confidentiality. Due to the characteristics of electronic documents, electronic files are not only easy to be modified and without any traces, but also can be transferred and replicated between different computers and carrier. Although some technology can prevent electronic file to be increased, cut or copied in the manuscript, the content is more possible to change than paper document. People can not tell the original from the handwriting, and seal or signature for each document, so they cannot determine what is the original electronic document from seal or signature. All the problems above are severe test of authenticity, reliability, confidentiality of electronic documents.

Suggestions can be adopted on file management in the environment of office automation

Improve the comprehensive quality of archives managers. Firstly, start from hardware construction and input to continuously improve the hard environment and the business skills of personnel files. Only increasing modernization hardware facilities, can archives personnel recognize

these devices, learn to enhance the business skills, and improve the management level. Second, the mode of "self-study, training supplemented" gradually form lifelong education mechanism and guarantee the quality of archivists changed with the times. Getting knowledge by constantly study is the fundamental way to improve the quality, so set up the incentive mechanism of the unit personnel files and consider the file service learning as a part of performance evaluation. Third, strengthen cooperation between archives departments to expand communication itself. Through the exchange, learn successful experience and methods of brother units, use the network and modern communication to expand file management information source and innovative thinking.

Make efforts to solve standardization problem of electronic archives management. The appearance of office automation, paperless and other things bring great changes in the formation of archives, such as document issued, reminders, filing and other process are carried out in computer and communication line. So archives must be readable file and their management mode has big difference with paper carrier archives. This change indicates that file worker will face more machine-readable form files. Setting normative, open, service, sharing file management system and standardization of basic business is a necessary prerequisite for electronic document management.

Set up unified standard. To do the archival filing management in office automation environment, we must proceed from the following aspects. First, set up standard system of document management. At present, records management and archives management of many units are separated and belong to different management departments. Archives department are often difficult to carry out early control, which accidentally become "ultra vires". Therefore, it must be regulated from the management system, and implemented unified leadership and planning in document management and archives management in the unit. File management-guidance and control should be took into the responsibilities of archives departments, which can ensure that the file forming, processing, archiving management, consult and other aspects are carried out under the supervision of archives departments. In system design, use the software system with strong compatibility and good application performance; regulate the related technical parameters and technical standards, including the standard of data interface, data security standard and different types of data transformation standard, which can ensure different types of sub files smoothly circulate and safely manage from office automation system to archives management system.

Formulate the corresponding file management law. The automation of archives management process is more and more quickly and also the general trend of archives management in the future. The advantage of managing archives through computer is very obvious. Compared to the old paper records, electronic files have great potential of development. The managers should be active to solve the corresponding constraints, because our country is ruled by law and everything should be carried out in accordance with the relevant legal provision, but also for the future of the archives management. The electronic archives can be modified easily and difficulty to be found, so the relevant departments should formulate corresponding laws to regulate these behaviors. Only the legal norms all details of electronic archives management, electronic archives can develop better. In addition, the corresponding penalties should be set up to the personnel violating the law. Then the related laws should be resolutely implemented. Electronic archives law should conform to the national idea of the rule of law, which has a very important value for the development of electronic files management.

Conclusion

In short, in order to better carry out the archives management in the environment of office automation, we must change the thought, use scientific minds to improve the level of management, keep pace with the times, and constantly put new technology in archives management. At the same time, we should adopt a variety of ways to overcome the drawbacks brought by office automation, which can improve the utilization rate of documents and serve better for daily work and management decision-making layer.

Key word: Digital Media Arts;disputed;development;application ;effect

Abstract. In 21st century, with the leaping advances in science and technology, computers and the rapid development of science and technology industry, formed by combining human intelligence and high-tech digital content industry that corresponds to the rapid development, and developing at an astonishing speed into a pillar industry of the knowledge economy in the new century. It is well known that digital media are based on digitized text, sound, images, Graphics, animation and video images as information carriers, through means of dissemination and development of science and technology. Basic characteristics of digital media arts: Cross uses online media which contains computer-animated production, the television advertising shoot, digital music player, there are activities such as online games, virtual reality, network, performance art, video, interactive installations and DV (digital video). This paper discusses the present status of digital media art, features, applications in education, vocational orientation and analysis of the development trend.

The rapid development of science and technology promote the application and development of digital media. Humans to combine high-end network technology and digital communications technologies effectively, gradually replacing traditional radio, television, film, and quickly towards the development of digital audio, video and film industries. Therefore, computer animation, virtual reality, digital industry information industry constitutes a new world, new digital media, and gradually developed into a huge industrial chain and ultimately progressive digital media arts industry occupies a pivotal position in knowledge economy.

An Overview of Digital Media Arts

Throughout recent years, digital media arts in a swift development in the era of knowledge economy. Digital media art concepts into people's hearts, we disagree, but for the most part the understanding is the same. Simply put, digital media creation and formation process of art is art. It depends on the development of computer technology and existing scientific research achievements in the field of information, images, artistic process them, to spread use of modern media, creating a digital media art. And other arts Compared to digital media art unique is its form of expression and artistic creation, in whole or in part based on digital technology. Produced by digital media or digital art design or Visual Arts are one of its manifestations. For now, vibrant digital media art is the art design and development potential of art. With the development of society and technology, digital media technology will render more unique and attractive to everyone.

Applied to Features of Digital Media Art

2.1 creation of digital media arts

Creation of digital media art not blindly rely on exclusive old crafts techniques, but use digital platforms to create unique and self-contained works of art. It's digital art works enable the audience to get involved and into the role 。 Interactions can subvert the role of public participation, public works not only effect change and have an opportunity to become part of the work.

2.2 performance characteristics of digital media art

Digital media art can be a simple split into "digital" and "digital art". Application of existing digital and computer technology can be understood as "digital". "Digital art" through "digital" works they create. The "media" is one of the digital art media.

Digital Media Arts Employment Orientation and Development Trend

3.1 employment development of digital media technology

Digital media art talent cultivation direction of talents of both technology and art, technology and art in digital media arts and complementary. Traditional education lacked both technology and art in digital media talent and training of such personnel in line with demand from emerging markets, their career major TV stations, film and television animation producers at all levels, Art, digital media and advertising company corporate image planning, exhibit design firms, branching, multimedia and Web design, interior design, product design and other popular industry. Exposure to developments in the field of digital media art is a wise choice, because it hides the huge potential for development. Digital Media Arts undergraduate approval formally adopted at the end of 2002 the Ministry of education, become subject to a new direction for the development of Arts and culture. After approval by, Tsinghua University, Beijing University, Zhejiang University, Guangdong University of technology and other colleges and universities started adding digital media art-related professions, to meet market demand. According to who statistics reveal that China's annual Digital Arts talent gap is 150,000. TV cartoon industry will see an annual market of 20 billion yuan. Broad markets and demand for multimedia industry evolved into huge economic industry 。 Some experts pointed out that, along with the development of science and technology, and also gradually raise the public requirements for Visual beauty.

3.2 industrial background of digital media arts

United Kingdom in developed countries, for example, in 2000 alone, the digital technology industry (including digital content) of annual output value of more than NT $ 60 billion pounds, while export value far more than £ 8 billion. Digital technology industry employs a total of approximately 1.95 million people, account for one third of GDP 7.9%. Data indicate that the digital technology industry is the United Kingdom's largest industry. United States, as the world's only superpower, to films and computer software as the main industries of digital technology, an annual turnover of more than $ 400 billion, 4% per cent of GDP. Even more striking is the digital technology industry (media art, video games, anime cartoons, and so on) in Japan's output more than twice times the GDP of this steel industry output in Japan of the digital technology industry has become the second largest industry after the auto industry. According to relevant statistics show that up to now, work directly with digital art with computers of nearly 100,000 people. In addition, more than 300,000 people a year receive digital industry related vocational skills training. Korea's digital technology industry with game industry is particularly famous, and has jumped among Korea's largest industry, even the car industry has followed. Digital technology industry's development in China is quite optimistic, and online games in this sector is particularly prominent. According to the international data Corporation (IDC) concluded that China's online game market compared with 2002, 2003 online game of rapid advancement of market development, reached 3.91 billion production value reached 1.32 billion RMB,2004 year RMBB net rose 2.59 billion RMB from 2003 to 2004, production value has quadrupled over b which data indicate that China's online game market potential, hides enormous business opportunities. In terms of animation, the Expert predicts: China's cartoon industry has a huge market, the output value is expected to reach 20 billion yuan. Merely developed cities in China, such as Shanghai, Beijing and Guangzhou youth anime consumption will reach 1.3 billion yuan. Consumers aged between 13 to 30 years of age. In addition, the animation industry could promote the development of industries associated with it, such as stationery, children's food, children's clothing, children's audio and various children's publications. The annual output value of the industry total was 205 billion yuan. The output was brought about by the animation industry, is a considerable income.

3.3 development of digital media arts

New aesthetics of digital media art features is its breaking into difficult and mysterious one thing everyone can accept and understand what forms of artistic expression, giving a visual feast. Digital media art art combines elements of science and scientific elements on a simple way of deciphering appeals to many people. Works downtown and brilliant, amazing and beautiful, is for digital media art through computers programmed to automatic interpretation and understanding. Both the art form and the content on your computer they all have the same sex. In the field of art, the development of digital media art is revolutionary in the field of subversion, with milestone significance. Different art information conversion can be achieved and everyone will enjoy the extraordinary Visual effects and artistic vision.

Digital media art with a triangular prism have striking similarities. Prism from different angles to the observer, which correspond to refracted rays are also different. Digital media art as well. Digital media art as a new art form, relies on digital technology and modern media technology, human rational thinking and perceptual thinking of art as one, given as a new and unique. It consist of art, science and technology layer, the media layer, the application layer overlapping compositions, includes a wide range of commercial design and popular art. Digital media authoring tool works of digital works interactive, polymorphism, and breadth of subject characteristics. Is rendered as: was the creation by all art forms (synthesis of art, video art, net art, etc) with a combination of computer technology, the Internet as a dissemination medium, the final step is combined with intelligent software, final artwork. Technological progress and innovation will be the concept of promoting the power of digital media art development, digital media and creative industries and information design is the art of the mainstream development, leading the artistic innovation of digital media art to the more extraordinary unique and wider, broader horizons of thought.

Conclusion

Derived from review on, development on both the means of digital media technology, transmission and dissemination of space provides a broader space for artistic creation. Digital media art will accompany humanity into "being digital" era gradually become the most representative form of art. Prospects for the development of digital media technologies will be invaluable. Based on this situation, productivity in the age of new media and digital information technology and penetration of digital media art have a growing impact on the development, so that the traditional art and traditional art and aesthetics of digital media more closely.

Keyword: The film; digital technology; development trend

Abstract. With the rapid development of modern science and technology, the development of digital movie is increasingly fast, digital film technology has gradually become the mainstream trend in the development of film technology.And its significance for regulating the film industry and promoting the sustainable development of the film industry is very important.The standards of digital cinema technology and traditional film technology are different, and grasp the full digital film technology standards, to fully improve on it and in the practice of the implementation is very important for the development of digital film. Therefore, we must attach great importance to the digital film technology, to enhance the capability of independent innovation of our country, and constantly improve after repeated practice, make contribution to the promotion of China's movie industry prosperity

One, foreword

The development of science and technology makes digital and film industry more quickly, the digital process of the film industry is irreversible, digital film technology thanks to the development of information technology and the rapid development of modern high-tech industry, which is leading the current society in many industries in a huge change. Digital technology, network technology and information technology deeply reflect the connotation of this change. As an important part of cultural industry, in the promotion of digital technology, the film industry has also launched a digital revolution in the global range, film of past is gradually began to change and the change was very rapidly. At present, the worldwide digital building of traditional film cinemas is faster and faster, after years of exploration and development, digital film technology in equipment, specifications, technical standards, the market management is more perfect.We can foresee, digital film technology in the near future will replace the traditional film and become the mainstream of modern film industry.

Two, digital film technology overview

Digital film technology standard ranges wider, it includes many aspects of filming, post production, data transmission, film screenings, safety management and other aspects. In order to have a better understanding of digital cinema technology standard, we must first fully understand the basic process of digital cinema system processes, drawings for digital cinema system, from the figure we can clearly see that, digital cinema system is fundamentally a typical multimedia information communication system, this system not only has the characteristics of multimedia information communication system, also has the movie's own characteristics, the basic process of the system is composed of a receiver, digital program source program and program transmission and digital cinema program receiving, storing and showing the program consists of four aspects.

Receiving the so-called digital program source usually covers photography, film digital program to digital, computer processing these three kinds of means; then the digital program post processing, there are usually nonlinear editing, color correction, subtitle synthesis and effects processing and other aspects. At present, a digital intermediate (Digital Intermediate) technology is gradually being used in digital film processing process; after the digital movie DCDM arises, digital cinema parent

version (Digital Cinema Distribution Master) is the non compressed picture, sound and letter data., it must formate Digital Cinema Package by JPEG2000 image compression,AES data encryption, MXF/XML package. AES data encryption technology (Advanced Encryption Package) is the advanced encryption standard, MXF are an emerging media formats (Material Exchange Format) represents the material exchange format, XML (Extensible Markup Language) Extensible Markup Language. DCP (Digitally Controlled Potentiometers) can be transferred via satellite, hard drive and optical fiber channel to digital cinema, when digital programming is transmitted to movie theaters, the first step will be stored, and then by playing a server solution for packaging, data decryption as well as processes such as image compression processing, after which you can use with digital projectors and other equipment for the audience playing digital movies. This entire process can be referred to collectively as digital film technology.

Three, the development trend of digital film technology

First of all, construction of digital cinema will be broadcast from a single digital storage devices into technology and equipment, management and services in one integrated solution. With the development of digital film technology, converging trends are bound to have a profound effect on digital cinema system as a whole, thereby allowing digital cinema with a deep and rich connotation, is a more accurate concept, with more robust capabilities. Digital cinema is not just for the future of digitizing broadcast system upgrades, but the entire upgrade digital theater systems, namely digital film programs are provided for digital cinema sets receive digital broadcast, digital storage, as well as services such as operations management, content of an integrated total solution. In order to adapt to this shift, the digital cinema should be the focus of future development and reform trend from digital theater systems and related equipment to the transformation of information management services. Construction and development of digital cinema will broadcast equipment from the past provide only a movie store provides a high quality service system and standard system changes, which includes storage and viewing of digital programming, broadcast quality, TMS digital cinema (Theater Management System Management System theater), NOC (Network Operation Center network operations center), and theater security content.

Secondly, the digital film-making technology and processes in the future will be continually optimized digital film technology production and digital content creation is continuous integration. As movie digital process of constantly advance, current movie produced process in the of core technology and past produced equipment of digital has get has basic achieved, movie industry future of development gravity will established in digital technology and corresponding of digital equipment based Shang, digital movie produced process will will more efficient, produced efficiency also will get effective improve, while VFX (Visual effects) technology of constantly universal using also will will let digital movie content with to audience of audio-visual feel more enhanced, Enhance the status of digital film competition in new media in the future. currently, digital technology has been widely used in field of digital filmmaking. In the coming period, various modeling and digital special effects, motion capture technology, synthesis technology, stereo image live preview and access to technology, three-dimensional animation, stereoscopic video production technology will be more widespread promotion and application.

Finally, the digital development of the film industry is now in a very favorable environment, it will generate a lot of produce each year best digital film being sent to digital cinema, take a lot of long habit of watching pirated audio-video products in the audience back to the cinema. Digital cinema's own charm in addition to the plot of the film to the audience from the rallying point of attraction, creative staff, including digital film technology to bring viewers the kind of impact on the Visual, auditory, or tactile and stunning. Without these factors, the digital cinema's fascination cannot be fully demonstrated. Also, modern digital technology development increasingly fast, its advanced of technology means will thoroughly change past film movie of broadcast mode, so, in future of is long a times in the, digital movie technology research personnel discussion and research of focus will will is how better of uses digital technology, and information technology and network technology, means, for my of movie industry chain links created out new of movie copyright

protection measures, and new of digital movie produced method, and new of digital movie transmission means and regulatory means,.

Conclusion

To sum up, the film industry's digital revolution where the movie has fundamentally changed for the transmission means to achieve a flowing transition from traditional film movie for the transmission of information. We can believe that, using broadband satellite communication network and fiber optic communications network for Film Festival ends transmissions to occupy a central position in a future movie technology, transmission speed as well as its influence would greatly improve competitiveness in a variety of new media digital film technology. It is worth mentioning that, digital standards of film technique and traditional film technology standards of the film is somewhat different, it must be repeated in the practice of continuous improvement, full understanding of the technical standards for digital cinema mastering, to full perfection of it development and implementation in practice for digital movies are very important. So, on digital film technology we must attach great importance to actively promote China's independent innovation ability, repeatedly practice continuous improvement at the same time, to contribute to promoting the prosperity of China's film industry.

Application of Virtual Reality in Forestry

DONG Wei[1, a], GU Weijiang[2]

[1,2]Nanjing Forestry University, Nanjing 210037,China

[a]Dongwei421@yeah.net

Key words: Virtual Reality Technology; application; landscape roaming animation; landscape architecture; development;

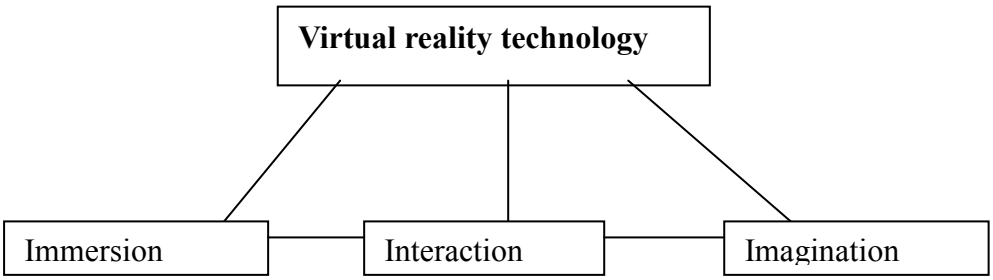
Abstract. The main characteristics and hardware requirements of Virtual Reality Technology are described in this paper, which summarize the application of virtual reality technology in landscape architecture knowledge, learning, teaching, training and scientific research process, and explore the use of digital city and landscape architecture technology platform to create multiple virtual laboratories and training station conception; it also analyze the influence of the virtual reality technology to teaching concept, teaching content, teaching means . In recent years, computer technology plays an important role in landscape design. Not only can it calculate the garden earth, draw the design of the plane and elevation renderings giving people with static visual experience, but also it implements the three-dimensional landscape animation with the development of computer hardware and software technology, especially the wide application of AutoCAD and 3dsMAX, so that people in the completion of the project can appreciate the pre-built landscape, having the strong performance of the dynamic three-dimensional force. However, the output for the landscape animation avi video format does not have real-time interactivity, which cannot satisfy people autonomy roaming; whereas the production process in the landscape roaming animation, 3D volume data in the scene has certain limitations, can not meet the 3D data volume expansion. The status of 1virtual reality technology and its application in the garden of the 1.1 virtual reality technology, virtual reality (Virtual Reality, abbreviated as VR, also known as VR) refers to the use of computer technology at the core.

Introduction

Virtual reality is a three-dimensional environment of computer simulation, which is a computer system that can create and experience the virtual world. It is related to computer, image processing, pattern recognition, speaking, audio processing, artificial intelligence technology, sensor, measurement, simulation of integrated technology and microelectronic technology. The user can get into the computer to see environment and object manipulation system and interacts with them.

The basic characteristics of virtual reality technology

The basic characteristics of virtual reality technology are showed in picture 1:



Picture 1

(1) Immersion

This refers to the true extent of the user as a protagonist in the virtual environment, virtual reality (VR) is the core of the system, the virtual environment ideal should reach the user is difficult to distinguish between true and false, the degree of be personally on the scene, even beyond the real. For example, the visual scene should be changed with the changes of viewpoint. [4]

(2) Interaction

Interaction refers to how much operational skill users control objects within virtual environment and the feedback of the natural degree from the environment, it is the key factor of interpersonal harmony. For example, the user can directly with the hand capture virtual objects in the environment, then the hand touch, and can feel the weight of an object in the scene, captured objects immediately with a hand moves. [4]

(3) Imagination

Imagination refers to the users who are enmeshed in multidimensional information space, rely on their own perception and cognitive ability in all directions to obtain the knowledge, to give play to the subjective initiative, thus generating new ideas and input to the system. [4]

Three stages in the development of virtual reality technology

The first stage: it was in the virtual exploration stage from 1950s to 1970s. America computer scientist I.E. Sutherland developed the first computer graphics driver's helmet display HMD and head tracking system in Harvard University in 1968, becoming an important milepost in the history of the development of VR technology. [3] The second stage: the basic concept of VR technology was formed from the beginning of 1980s to the mid of 1980s. It came to practical stage from test stage. The important symbol is the VIEW virtual reality system completed in 1985 under the leadership of Michael MeGreevy. The third stage: it is in virtual reality development stage from the end of 1980s to today. Virtual reality technology had from the laboratory to the market, which had been gradually applied to many fields. [1]

Application in virtual reality technology, manufacturing industry, the building and Education

Application prospect of virtual reality technology is very broad, it began in the military field, has been applied to manufacturing industry, architecture, and medicine, education, entertainment and business fields. The following a few main application examples: Virtual display of virtual design technology in the manufacturing industry mainly includes the product appearance and layout, the kinematics and dynamics simulation of products, product assembly simulation, virtual prototype and product performance evaluation, advertising and roaming product, enterprise production process simulation and optimization of virtual enterprise and cooperation simulation and optimization.

Virtual virtuous technology in architectural design, real estate and decoration has a broad application prospect. The introduction of virtual reality technology, allows the designer to design in the construction phase can be visual, dynamic way of all-round display of different construction schemes and construction measures, so that people can in a virtual environment, even roaming in the future within the building, which can quantitatively completed scheme comparison, selection and will optimize the construction scheme, realize the optimal construction. Applications of virtual reality technology in education have three kinds: (1)Virtual University, namely the use of virtual technology to create on the Internet, no consumption of educational resources, to students or

teachers for virtual classroom virtual reality object; (2) virtual laboratories, we can avoid some real test experience brings danger. [1]

Virtual plant

Virtual reality technology has penetrated into many areas in all walks of life to develop their own, seize the opportune moment, in the use of this new technology, however, the application of virtual reality technology in forestry application is few, referring to other industries, the virtual reality technology in forestry production, scientific research and teaching areas will be more and more broad prospects. This is the so-called "virtual plants". [2]Considering the plant physiological and morphological structure, virtual plants in two aspects, can be used to carry out a series of virtual experiments. For example, Hort Research Institute of New Zealand using virtual crop technology team Kiwi improved varieties of virtual reality system, three-dimensional fruit research team to develop, so that people can watch three-dimensional fruit germination, growth, branching, leaf, flower on a computer monitor, results and fruit growth, growth cycle is shortened to one year in less than a minute. Using virtual plant technology can be very intuitive to study on forest ecological system is complex, it is found that the traditional research methods and technical means it is difficult to observe the law. The position relationships between spatial distribution in post groups and pest pesticide use virtual simulation, the optimal spraying method determines pesticide.

Design and manufacture of forestry machinery

With the development of science and technology, design and development of technology for forestry machine system requirements are increasingly high, but due to the complexity of work environment and forestry machinery design limited funds, especially in the mechanical design of mechanical kinematic scheme, and all kinds of transmission machine simulation before processing, comprehensive analysis of the whole process. [3]Application of virtual reality technology imitates the mechanical movement, and through to power for the driver, and then assign to each part of different materials, not only the whole organization movement according to the predetermined manner, and the kinetic parameters and kinematic parameters of each point can be automatically generated by computer. This will greatly improve the work efficiency and the success rate of design people.

Conclusion

As the crisis spread, can establish a virtual farm using virtual plant model, make forestry production or internship students planting virtual crops and virtual forest management in the computer, the dynamic process of growth status of crop, and by the change of environmental condition and cultivation measures, visual observation of crop growth status changes, it can the traditional methods cannot achieve the effect, especially for forestry science promotion, will enable producers to more easily understand and grasp.

Virtual reality technology will be used for forestry resource allocation, the establishment of virtual system; can be beneficial to consider various factors, evaluation and comparison of design, to achieve the optimal allocation of resources. [5]For example, the quarry started in the former to make a research report on the impact; operators should make the area of vegetation restoration at the end of the work plan. It can show the various stages of the whole vegetation restoration by using virtual reality technology. Virtual forest management need to construct fusion forest object model, growth model, the forest environment model, GIS data for an interactive 3D virtual forest visualization platform. In the course of forest management in particular, simulation of the whole process and the effect of forest management in the 3D virtual scene, with the comprehensive

analysis of remote sensing, GIS, evaluation and optimization of the business plan, and provide the basis for forest management decision.

Optimized Analysis of Cyber Topology Based on Reliable Restraint

YAN Han[1, a]

[1]Kunming University of Science and Technology, Kunming 650504,China

[a]YanHan421@yeah.net

Keywords: Reliable restraint, cyber topology, optimized analysis

Abstract. As telecommunication network is rapidly developing, modern telecommunication network is inclined to be in possession of large scale, sparse topology as well as high capacity. At present, these concerns have increased in network design and enhanced the exploration in the field of cyber topology. With network technology on the rise, especially the expansion of high-speed network telecommunication, scale of network is becoming larger and larger with much more volume of chains.

According to the real situations of optimized analysis of cyber topology based on reliable restraint, this passage is to put forward optimized ideas based on reliable restraint and design solving models.

Subject backdrop and importance of research.

In the process of designing a new network, designers must make sure of the structure of cyber topology, distribution of chain volume and traffic and network's stability and reliability.

For a network at hand, people in charge of network management have to firstly ask the following questions. Does network operation work well? Is there any property neck in the network? If there is, how can we get rid of the property necks through network updating and re-installation?

As telecommunication network is rapidly developing, modern telecommunication network is inclined to be in possession of large scale, sparse topology as well as high capacity and network reliability becomes more prominent and important. Reliability plays a vital role in the design of telecommunication network and property assessment. Generally speaking, telecommunication network includes network's existence, anti-destruction and usability, involving network telecommunication devices, topology structure and telecommunication treaty. With the constant development of science technology, network reliability in electric circuit, traffic, airplane line and power grid transformation. Therefore, network reliability owns a wide range of application.

Since the 1980s, some developed countries have devoted a large amount of fund and labor to network design, simulation and property analysis, creating a set of instruments for network optimization and property assessment which are able to effectively simulate various cyber environments. However, the design of computer network in our country mainly count on manual labor. In such a circumstance, research of network optimization and design and property assessment means as well as development of a whole set of cyber simulation instruments will be meaningful in research with a wide scope of application value.

Calculation of all-node reliability.

All-node reliability, the most popular reliability assessment method for branch network design, means the probability of connection between all nodes in the whole network. Analysis of network reliability based on connection is a classic problem in the research of network reliability, greatly significant to the research of any node's reliability in a random network.

Thus, it will be necessary for researchers to research from two respects. First of all, figure out the absolute upper and lower bounds of network reliability through algebra structure. Secondly, by means of simulation of part of the entire network, acquire the sampling information and finally the point estimation between all intervals.

2.1 Factor theorem.

Topology structure can usually be depicted by an abstract graph, generally expressed with G=(V,E) in which V is the collection of nodes and E is the collection of sides.

Network reliability R(G, q) is generally defined as the probability of connected status G keeps. G=(V, E), q is the breakdown probability of all sides in the network(the working probability p=1-q).

To suppose G is an undirected graph with equal working probability p in all sides and e∈ G for any random side. According to the above principle, a formula can be demonstrated like below:

$$R(G,p)=p\times R(G*e)+q\times R(G-e) \tag{1}$$

in which q=1-p is the breakdown probability of the side e.

After the decomposition of factor theorem, the son graphs G-e and G*e will decrease with invariability of reliability degree, cycling after their combination until the graph simplifies or its number of connected branches surpasses 1(or gets unconnected).

2.2 Upper bound value of number.

d1, d2, d3.....dn is an extent queue of the nodes in G and the breakdown probability of each side is q. Thus, the formula which calculates the upper bound value of number for G's all-node reliability can be indicated like below:

$$R(G)\le 1-\{\sum_{i=1}^{n} q^{di}\prod_{k=1}^{mi}(1-q^{dk-1})\prod_{k=mi+1}^{i-1}(1-q^{dk})\} \tag{2}$$

In formula (2), mi=min(di, i-1), i=1,2,3...n.

To suppose h(d1,d2,..dn) expresses the maximum of R(G), all-node reliability of network, thus, hereby the below formula can be demonstrated:

$$h(d1,d2,...dn)=1-\{\sum_{i=1}^{n} q^{di}\prod_{k=1}^{mi}(1-q^{dk-1})\prod_{k=mi+1}^{i=1}(1-q^{dk})\} \tag{3}$$

To figure out the upper bound value of number for G's all-node reliability, the extent queue of G's nodes d1,d2,d3,...dn must be found out first. In addition, according to formula (3), h(d1,d2,d3...dn) will lead to the upper bound value of number.

The above method is relatively convenient and simple to operate compared with other ways in the process of calculating the upper bound value of number.

2.3 Comparison of the above two methods.

This paragraph is to introduce a network topology structure graph of dodecagon. Figure 1 will respectively make two topology structure graphs through eliminating chains or adding chains , including 24-chain graph and 40-chain graph.

24-chain:eliminating chains, {1,3},{5,10},{6,7},{8,9},{11,12},{15,16}.

40-chain: adding chains, {3,6}, {3,9}, {6,11}, {7,8}, {9,16}, {11,16}, {12,13}, {14,15},{15,20}, {12,20}.

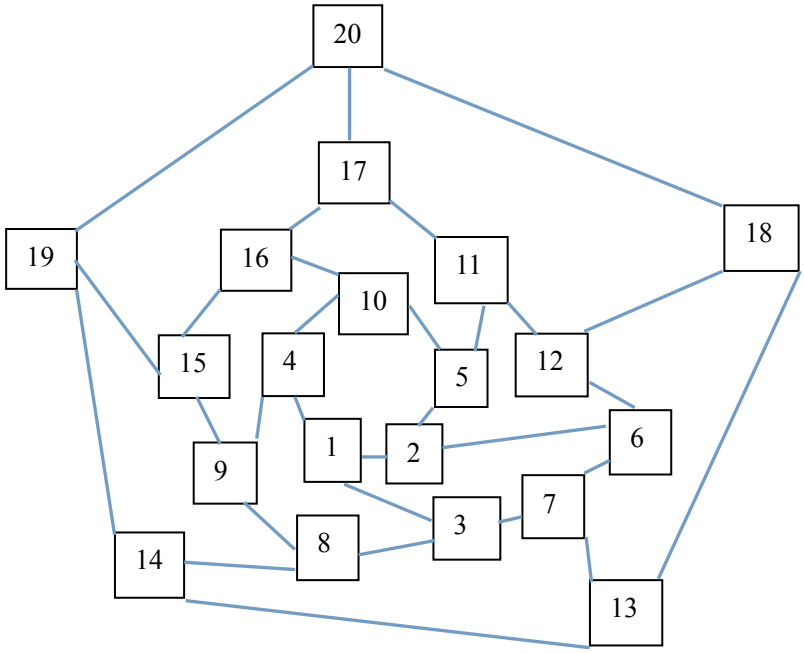

Figure 1. Graph of Topology Structure

Reliability of each chain equals to 0.9, 0.95 and 0.99. “fr” and “ur” respectively expresses the numbers of both factor theorem and upper bound value of number to calculate all-node reliability. In order to illustrate the accuracy of “ur”, this paragraph is the compare the discrepancies between “fr” and “ur”, discrepancy equal to |ur-fr|*100%. Both “fr” and “ur” are operated in the environment of VC++6.0. Figure 2 indicates the comparison between “fr” and “ur”. The following is the detail.

	Factor Theorem	Upper Bound Value	|ur-fr|*100%
G=<20,24,0.9>	0.782978	0.890838	10.79
G=<20,24,0.95>	0.945	0.969827	2.48
G=<20,24,0.99>	0.997944	0.998717	0.08
G=<20,30,0.9>	0.977131	0.980651	0.352
G=<20,30,0.95>	0.997312	0.997519	0.02
G=<20,30,0.99>	0.99998	0.99998	0.0000
G=<20,40,0.9>	0.991072	0.990769	0.0303
G=<20,40,0.95>	0.998942	0.998855	0.0087
G=<20,40,0.99>	0.999992	0.999991	0.0001

Figure 2. Comparison of All-node Reliability

To draw a conclusion from the above graph, the method of “ur” possesses more advantages than “fr”, including simple realization, relative accuracy and efficiency.

Network optimization design based on reliable restraint.

Network design problem includes Unlimited Network Design Problem and Limited Network Design Problem.

Unlimited Network Design Problem refers to the topology design meeting the needs of connection degree and reliability satisfaction with the least cost, including Steiner tree, Existence network design problem and Reliability network design.

To take into comprehensive consideration existence of network, network fee and property assessment, a concrete model can be depicted like below.

Given Conditions:
(1) Telecommunication matrix between nodes.
(2) Possible chain volume number.
(3) Telecommunication fee function.
(4) Probability of chain reliability.
Variability of What's Optimized.
L----Network topology structure.
Property Index.
Z---total network fee.
D---Prolonged time from average node to each node.
R---Network reliability.

Summary

With telecommunication network prospering in the contemporary society, modern telecommunication network is inclined to be in possession of large scale, sparse topology as well as high capacity. Currently, these concerns have increased in network design and enhanced the exploration in the field of cyber topology. With people's attention focused on network, especially the expansion of high-speed network telecommunication, scale of network is becoming larger and larger with much more volume of chains.

[a] wangzhikun022@yeah.net

Keywords: complex network theory, computer network topology, research

Abstract. If we apply the system internal elements as nodes, and the relationship between the elements as connection, then the system form a network. If we put emphasis on the structure of the system and analyze the function of the system from the angle of structure, we'll find that real network topology properties differ from previous research network, and has numerous nodes, which is called complex networks. In the real word, many complex systems can be basically described by the network, while the reality is that complex systems can be called as "complex network", such as social network, transportation network, power grids and internet etc. In recent years, many articles about the complex networks are released in the international first-class publications such as Nature, PRL, PNAS, which reflects that the complex networks has become a new research focus.

Complex network theory.

1.1Brief introduction of complex network theory

Complex network is a network which has part or all of the nature of scale-free, small world, attractor, self-similarity, self-organization. The main contents of complex network theory are: the evolution characteristics of the network, evolution law, dynamic mechanism, the statistical law of evolution and the characteristics of the network model. In natural science, the most basic part of the study of complex networks including: degrees, the degree of relevance, agglomeration, the shortest distance, the number of interfaces, and their distribution characteristics.

1.2Characteristics of complex network system

Complex network system has the following characteristics:

(1)Small world. Complex networks explain many complex networks in the reality through a simple description, and believe that no matter how large the network is any two nodes in it are connected by a path. Complex network system explains that no matter what the world is it is connected through the relationship among very small innumerable nodes.

(2)Gregariousness. Complex network will become more and more gregarious, which means it has a tendency of cohesion, in other words, many connected cohesive small network will be distributed in the same big network.

(3)The power law distribution. Degree means the nodes in the network and the quantity of the connected nodes. The degree correlation is the compactness between each node. Connection is the amount of nodes that pass one node with the shortest path.

Application of complex network.

Research on network structure is important, but the ultimate goal is to understand and explain working modes of these networks by studying structure, and then to forecast and control the behavior of the network system. We call the system dynamic properties based on the network as dynamic behavior on the network, it covers many aspects such as system seepage, synchronization, phase change, the network searching, navigation and so on.

People are becoming more and more interested in the research on network propagation behavior. The traditional network propagation models are mostly based on regular networks. the key to the research of network propagation model is the formulation of propagation rules and the selection of network topology structure.

Both in regular networks and small-world networks, there is a transmitted intensity threshold, while the threshold is very close to zero in scale-free networks. Research shows that the real world network has both the characteristics of small-world and scale-free. Once the virus infection intensity is large, we must attach great importance to the harm. We cound not completely depends on the improvement of medical and health conditions to make it under control, we should isolate it to protect some nodes, and cut off the related links to interrupt transmission in order to change the transmission network topology.

Basic models of network topology.

The simplest network is regular network and its feature is the amount of nodes close to each node is same. In the late 1940s, Paul Erdos and Alfred Renyi put forward a new kind of network model that is random-network model. But it can not perfectly describe the properties of the real network, so people put forward some new models.

3.1Small-world networks

We find from the research results that most of the real networks have the properties of small world and gregariousness, which is shown in the chart one. Although regular network has gregariousness, its average shortest path is longer; random network is just the opposite, it has the character of small world but its clustering coefficient is quite small.

Network	Size	<k>	l	l_{rand}	C	C_{rand}
WWW, site level	153127	35.21	3.1	3.35	0.1078	0.00023
Internet, domain level	3015-6209	3.52-4.11	3.7-3.76	6.36-6.18	0.18-0.3	0.001
Movie actors	225226	61	3.65	2.99	0.79	0.00027

E. coli, reaction graph	315	28.3	2.62	1.98	0.59	0.09
Silwood Park food web	154	4.75	3.40	3.23	0.15	0.03
Workds synonyms	22311	13.48	4.5	3.84	0.7	0.0006
Power grid	4941	2.67	18.7	12.4	0.08	0.005
C. Elegans	282	1.4	2.65	2.25	0.28	0.05

Chart 1 Small-world phenomenon in the real networks

We can see from chart 1 that regular networks and random networks cannot perfectly show the character of the real network, which means the real world is neither complete absolute nor random. Watts and Strogatz put forward a network model with both small-world and gregariousness. It is between regular networks and random networks (WS network for short).

3.2Scale-free networks.

For most of the massive real networks, test results suggest that using power law distribution to describe its degree distribution is much more accurate.

Network	Size	<k>	C_{out}	C_{in}	l_{real}	l_{rand}	l_{paw}
WWW, site	325729	4.51	2.45	2.1	11.2	8.32	4.77

Chart 2: Scale-free phenomenon in real network

Chart 2 shows that when compared to exponential distribution, power law distribution has no peak in its graphic, most nodes only have a small number of connections, and a few nodes have large connections. There is no characteristic scale in random networks. Barab and Albert put forward the famous BA model.

Analysis on the network topology.

4.1The features of network topology

In recent years, for the research of Internet topology, the power-law distribution of node degrees is the most important finding. This distribution shows certain stability in different scale of network topology, which also means that in different scale of Internet topology, its node degree shows some kind of power-law distribution that is:

$$P(k)=k^{-\beta} \quad (1)$$

Generally, β fluctuates in a small range within 2 to 3, k refers to the degree of node, P (k) suggests the appearing probability of the node k, which is the distribution rate.

Internet as a complex network, from the purpose of its communication network optimization, the main targets of the topology optimization are minimizing the average distance between nodes and the network edge. The trend of the future communication network is small world network. But the Internet network covers a large range; the development of its topology structure is also facing many technical problems. Although the development of the Internet can't achieve the overall optimization of topology design, its small world, less edge, high gregariousness show that Internet has the characteristics of small scale optimization. So, the Internet topology is also a dynamic process. Prior connection rule says that the new node enters into the Internet network, namely the new node to join the network will choose nodes with large number of connections.

4.2Construction of computer network topology model

More people choose network topology regulation such as prior connections and growth to build the model of Internet topology. Its main purpose is to make realistic topological model be created automatically through simple evolution.

Now, building Internet model is mainly based on autonomous domain and routers, but because the Internet network topology shows some similarities in essence in different levels and different scales, the topological model based on the rules of prior connection and growth fits the two scales.

Summary

The most important features of complex network theory are scale-free property, small world effect, the power-law distribution of node degrees. The Internet has these properties, and shows these properties during the building and forming of its topology structure. The topology rule is that the network nodes in growing and prior connection. Through its continuous growth and prior connection to the new node to make the network topology become a kind of self-organization and transfer process.

Keywords: Multiple website, browsing behavior, eye movement theory,model

Abstract. With the rapid development of computer technology and telecommunication, the whole world has been interconnected by Internet which is playing an indispensable part in our daily life. Websites are like windows for users coming into the Internet and leading us to another world. A great amount of information can be browsed in a convenient way through websites, thus, they occupy largely important positions in the contemporary society.

Therefore, research on the laws users browsing the Internet will definitely help us better get an understanding of the features of Internet. This passage is to make every effort to research multiple websites as well as users' browsing laws with some practical examples, effectively making full use of netizens' documents and statistics such as Cookie.

A general introduction of Internet.

Internet can date from the year of 1969 when American Defense Department supported a project about expansive network, named APPA net.

Four computers were interconnected with each other at the very beginning and the number of network nodes reached 57 in the year of 1977 with more than one hundred computers of various kinds. Until now, Internet has been a network in possession of over ten billion netizens in the entire world.

In view of convenience, reliability and pragmatic value, Internet is expanding in an unprecedented speed and has exert enormous influence on global politics, economy,culture as well as people's life. Different from traditional industrial economy and agricultural economy, the inter drive of new economy in the 21st century is Internet.

Like other businesses, the process of professional division of labor after Internet has developed to a special degree will make some subtle change in the internal part of Internet, forming several levels from high to low. From the common angels of the field of Internet, several structures are included: Access and Platform, Internet Content Provide as well as E-commerce. Access and Platform is one of the most original business forms of Internet, involving wire access and website maintenance. Internet Content Provide provides users various kinds of information and district service. E-commerce is a newly creative way for people trading on the Internet, involving Web technology and some electronic means. The fast rising of E-commerce will undoubtedly enrich Internet.

Analysis on features of Internet users.

2.1Users' needs

Need means a status of users who are desperate to obtain something they lack physically and psychologically. Needs can be divided into several kinds according to different principles such as physical and psychological needs, material needs and spiritual needs. In Internet consumption, consumers demonstrate some new needs. First of all, need of interest. The majority of people choose to surf the Internet for their interest which originates from exploration and success.

Exploration comes from the Internet of great abundance, containing various knowledge and information for netizens to explore. Secondly, need of gathering. Mankind, social animals virtually, have the needs to take part in the group activities. In such a circumstance, the appearance of Internet make it possible for people to get together in this fictitious world.

2.2Division of Internet users.

Characteristics of Internet users are mainly decided by external and individual factors. External factors included culture, society and family. Individual factors include life period, job, revenue, living style as well as self-conception. All of the above factors will exert influence on netizens' Internet behaviors. According to these factors, four groups can be concluded as below.

Firstly, trade group. The trade activities Internet users participate are concrete. Members of this group trade and purchase with some special purposes in the process of communicating with other members in order to acquire much more business information.

Secondly, interest group. Members of this group surf the Internet based on the interest in some activity. Compared with trade group, members of interest group pay more attention to communication of the information they are interested in.

Thirdly, illusion group. Members of this group fail to demonstrate themselves and addict themselves in illusion, imagining to create a character which is far from reality, such as writing novels or playing Internet games.

Lastly, relation group. Members of this group usually experienced some life frustration such as disease or failed marriage, searching for chances to communicate with other on the Internet with real identity.

2.3 Browsing behaviors.

Netizens' behavior changes can be divided into three phases when they are visiting the websites.

Leave right away. When a consumer is surfing a website, if the website design is totally far from what they favor or much too complicated, the consumer will leave right away without hesitation. As a consumer is visiting the website, if the website design is totally far from what they favor or extremely complex, the consumer will leave right away without any hesitation.

Browsing. The elegant design of website surface causes consumers' interest. However, interest fails to lead consumers to further registering or consume on the Internet.

Browsing and consuming. Consumers purchase something on the Internet due to stimulation of the beautiful website surface design as well as the desires caused in the process of browsing. Finally, they succeed in consuming on the Internet. Therefore, Internet users' browsing behaviors constantly change in the process of browsing.

Analysis on clicking frequency based on hours.

This paragraph is to draw a figure based on hours with netizens' Cookies to investigate the netizens' clicking frequency and visiting situation in all websites.

Figure 1 is drawn according to the clicking number every hour in Pchome online, MSN and Hinet.

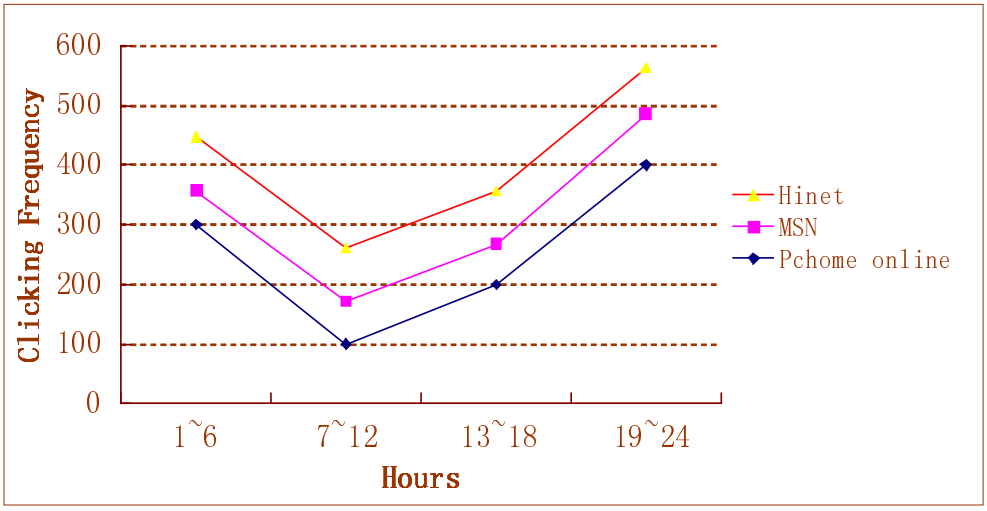

Figure 1. Clicking Frequency in 24 hours

Figure 1 clearly indicates the changing conditions in 24 hours. According to the above figure, netizens' browsing behaviors in a single day can be divided into fours phases: Dormancy Hours (one o'clock to six o'clock), Revival Hours (seven o'clock to twelve o'clock), Stable Hours (thirteen o'clock to sixteen o'clock), Peak Hours (nineteen o'clock to twenty-four o'clock).

In Dormancy Hours, the number of visitors surfing the Internet severely decreases and clicking frequency of users correspondingly reduces. In Revival Hours, the number of visitors surfing the Internet gradually increases and clicking frequency of users is also constantly rising. In Stable Hours, both the number of visitors and clicking frequency are kept in a smooth condition. In Peak Hours, most of the users take active part in the network and the number of visitors reaches a peak status.

ARMA model.

According to Figure 1, the clicking frequency in Pchome online, MSN and Hinet fluctuate in a special period. Thus, this paragraph is to apply ARMA model, analyzing users' browsing behaviors in websites.

Box-Jenkins modeling recognition method will be applied so as to initially recognize AR(p), MA(q) and ARMA(p, q).

According to the statistic features of ARMA sequence's self-correlation function and partial autocorrelation function, the model type can be initially confirmed. Figure 2 shows the model judging codes.

Model	AR(p)	MA(q)	ARMA(p,q)
Self-correlation Function	Trailing	Truncation	Trailing
Partial Self-correlation Function	Truncation	Trailing	Trailing

Figure 2. Codes of Model Judging

If the sequence ρ_k is truncated at q (when $k<q$, ρ_k approaches zero weakly, but when $k>q$, ρ_k apparently approaches zero) and the sequence φ_{kk} is restraint to zero, it can be judged that X_t belongs to sequence MA(q).

In addition, AIC code can also used to initially judge the model. To suppose $\{X_t$， 1<t<N$\}$ is a random sequence and the function of AIC code can be shown through the below formulas:

$$AIC(p) = In\overset{2}{\underset{a}{\sigma}}(p) + 2p/N \quad (1)$$

$$AIC(p_0) = \min_{1 \le p \le P(p)} AIC(p) \quad (2)$$

In the above formulas, the number of AIC increases with the increasing of p.

Summary

As computer technology is rapidly developing in the contemporary society, people's way of communication as well as life structure are largely changed. In this revolution, websites undoubtedly play a vital role. What's more, website enterprises are also faced with great challenges and opportunities. These enterprises must get a good understanding of the laws of users' browsing behaviors in the process of development and survival. Besides, interactive activities and rich details of the websites are essential for the existence of websites.

Keywords: network, access control protocol, AES, virtual private network.

Abstract. This paper mainly analyzed the security of AES(Advanced Encryption Standard) protocol and virtual private network technology ， the network 802.3 and 802.1x/EXP security vulnerabilities: defects of Service Set Identifier and MAC Address Filtering, defects of User Authentication Method, security vulnerabilities of WPA Algorithm, defects of 802.1x / EAP and RADIUS Authentication, etc. The authentication and encryption method to improve network security measures.

Introduction

It has been proven that there are serious flaws in the security technology of network, which brings serious harm to the users. Therefore, it is necessary to implement technological improvement and take effective security solutions to improve the security.

Security Flaws of 802.3 Wirelesses network

1.1 Service Set Identifier (Service Set Identifier) and MAC Address Filtering Defects. Service Set Identifier is mainly used for carrying out access control for closed networks. There is access MAC list for recording the address of Network Interface Card, refusing station whose MAC address is not in the list. As the information of Service Set Identifier and MAC address is transmitted in the form of plain text in the network, it can easily be stolen by the attackers, and most network card is allowed to be changed by the software, the attackers could invade the network by impersonating legitimate users.

1.2 The defects of User Authentication Method. 802.3

Standard defines two authentication methods [1]: open authentication and shared key authentication. The former allows any stations to access the networks, communication package is transmitted in the form of plain text. This method does not have authentication mechanism and security. The latter belongs to request-response authentication mechanism: AP receives the request for access to information of STA sending the inquiry information, STA uses shared key to encrypt for the inquiry information and return to the AP, AP decrypts and verifies the integrity of the message. If authentication is successful, you can access the Wnetwork. As long as the attackers grasp the inquiry information before and after the encryption the inquiry and get through simple mathematical operation to get pseudo random stream ciphers generated by shared key, and then forge the legitimate response message to access Wnetwork through AP authentication.

1.3 WPA (Wired Equivalent Privacy) Algorithm with Huge Security Vulnerabilities

1.3.1 WPA encryption and decryption mechanism. WPA algorithm is RC-4 stream cipher algorithm based on the design of RSA Company. WPA encryption is executed on the second layer of the MAC sub-layer. AP and all workstations connected to the access point must use the same shared key. For package transmitted in any direction, the transmission process connects the contents of the packet with the inspection and combination of the package. And then, WPA standard requires transmission procedure to create an IV (Initialization Vector), which is specific to the package, the latter is combined with the secret key for encrypting the data packet. The receiver generates its own secret key matching data packet and with it used to decrypt the data packet. As shown in Fig. 1.

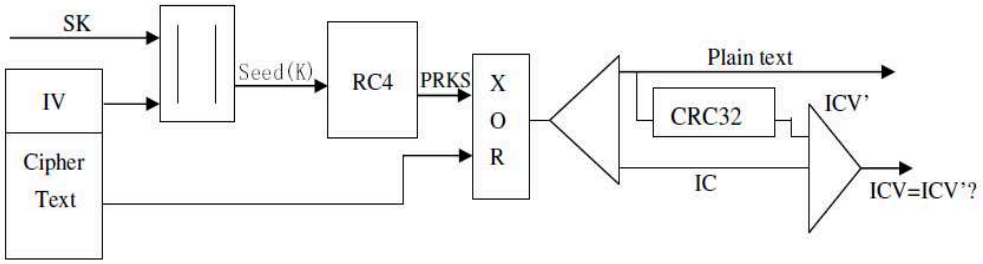

Fig. 1 Block diagram of WEP protocol decryption

1.3.2 WPA security issues. (1) Limitations of IV. In the actual products, the IV is generally achieved by the counter whose capacity is only 24Bit [2]. IV will be repeated and cycled once a few hours each in the busy Wnetwork. The two sides provide up to four frame shared WPA secret key in the communication protocol. Each WPA frame can select a WPA secret key, and is combined with IV in the frame to form the seeds of WPA PING, and generate WPA encryption key stream. However, there are only four selections for WPA secret key, it is prone to duplicate. And it is easy to identify whether two different frames use the WPA secret key because of IV and WPA secret key are transmitted in the form of plain text in the WPA frame. When the attackers find two different WPA frames use the same IV and WPA secret key, carry out XOR operation on the cipher text of WPA frame.(2) CRC-32 Issue. CRC-32 check-up algorithm in the WPA is linear, which is used for detecting whether the WPA frame is tempered by the intruders. But it does not have message authentication function required by the resistance to malicious attacks. Suppose the plaintext is P, cipher text is C, tampering data of the attackers is Δ, the plain text and cipher text tampered are P' and C'. Since CRC-32 is without secret key, carry out XOR operation with WPA frame data to complete encryption. However, in the WPA data frame, the first byte is header information, it is the same for each WPA frame, and the attackers can easily break: XOR with the cipher text can get the first byte of the key. IV is transmitted in plain text, which is easy to be intercepted. S.Fluhrer, I.Mantin and A.Shamir prove: use IV and the first byte key stream and combined with RC-4 features, you can gain the WPA key. And in RC-4 algorithm contains weak key, that is, secret key and the encrypted data packet are related. If the attackers collect enough weak keys, they can use the statistical analysis to obtain the entire key.

The Defects of 802.1x / EAP and RADIUS Authentication

IEEE 802.1x protocol (Port Based Network Access Control Protocol), the main purpose is to solve the access authentication issues for users of network, and provide a kind of authentication and authorization for the users connecting to the network to accept the legitimate users and protect the network security. IEEE 802.1x port control structure is shown in Fig. 2.

The authentication server will open the controlled port of validating entities (it is AP in the Wnetwork) When the terminal is authenticated, the terminal can access the network through the port, otherwise, the terminal is prohibited from sending data. There will be problems of lacking of mutual authentication, because the "Man-in-Middle" just need to fake the successful authentication information, it can make the terminal enter the "authenticated" status, successfully deceive the terminal and steal its transmission data. The various authentications of EAP are not perfect yet, there are still many security vulnerabilities, and you will suffer the rejection of service and the attacks from Man-in-Middle, etc.

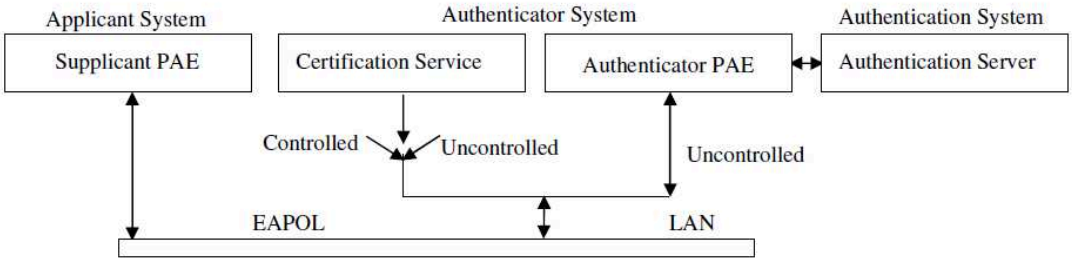

Fig. 2 IEEE 802.1x

AES(Temporal Key Integrity Protocol) and virtual private network (Virtual Private Network) Security

Analysis

AES [4] is improvement program of WPA. AES extended WPA key's length from 40Bits to 128Bits, and extended IV from 24Bits to 48Bits, and added the "Key Mixing Function", "Replay Protection Mechanism" and "Message Integrity Checking", etc, which increased the intensity of encryption security. However, AES is based on RC4 encryption algorithm the same as WPA, even if it increases the length of the encryption key, it is impossible to enhance its security level because of the lack of RC4. Increasing the length of IV can enhance the difficulty in decrypting to limited extent, it can't solve the problem fundamentally such as extending collection time of decrypting information. AES is just a temporary transition program rather than a final program.

Development and Security Strategy of network Security

There are more security flaws in the security mechanism based on WPA protocol and security risks in AES protocol applied in network, which make many security threats to current network. A new generation of security technology IEEE802.1 II protocol proposes a long-term and complete security assurance framework of network.

4.1 Improved Data Encryption Protocol. Given there are various security flaws in WPA, WI-Fi Alliance releases a interim agreement WPA (Wi-Fi Protected Access), WPA uses a new algorithm to solve the flaws of WPA on encryption and data checking. WPA mainly completes the following tasks: solve the main security issues of WPA, especially for its vulnerabilities on shared key: Add user-level authentication measures; solve the problem of system upgrade. The existing Wi-Fi certified products of network can achieve WPA through software upgrade.

4.2 Improved Authentication Mechanism. Since the basic authentication mechanism specified by IEEE 802.3 standard is too simple to provide the reliable security defense for network. 802. Ix authentication protocol uses EAP to handle the authentication request of client. Authenticators create a logical port for them according to association ID of each applicant; each logical port has two states: unauthorized and authorized. When the port is unauthorized, it can only send and receive 802.Ix protocol data packet, while data packet of other protocol type is blocked.

Conclusions

For continuing expansion and increasing demand of network, it puts forward higher requirements for network security. It is impossible for simple enhancement of security protocol of single layer or using one kind of means to solve all security issues of the network. Therefore, the network can use various technologies, such as IPSec virtual private network, Service Set Identifier access control, upgrade Wi-Fi encryption, MAC address filtering, firewall and intrusion detection, etc. to protect network security. Using various security technologies to establish multi-level security system is developing direction of network security.

A radio Link Logical Relationship Between And One Network Apparatus

Wu Chuansheng

Software College, University of Science and Technology Liaoning,China

gykwcs@163.com

Keywords: radio Link,network apparatus,network, handling barred ,cell

Abstract. MAC layer, a radio link control (RLC) layer and a broadcast and multicast control (BMC) layer exist in a second layer. The MAC layer maps various logical channels to various transport channels and performs logical channel multiplexing to map a plurality of logical channels to one transport channel.The MAC layer is connected to the RLC layer, which is a higher layer, through a logical channel. The logical channel is divided into a control channel for transmitting information on a control plane and a traffic channel for transmitting information on a user plane, according to the kind of transmitted information.

0 Introduction

The MAC-b sublayer is responsible for management of a Broadcast Channel (BCH) which is a transport channel for broadcasting system information, the MAC-c/sh sublayer is responsible for management of a Forward Access Channel (FACH) common transport channel shared with the other UEs, and the MAC-d sublayer is responsible for management of a Dedicated Channel which is a dedicated transport channel of a specific UE. In addition, the MAC-hs/ehs sublayer manages a High Speed Downlink Shared Channel (HS-DSCH) for high-speed downlink data transmission and the MAC-e/es or MAC-i/is sublayer manages an Enhanced Dedicated Channel (E-DCH) which is a transport channel for high-speed uplink data transmission.The RLC layer guarantees Quality of Service (QoS) of a Radio Bearer (RBs) or data transmission. The RLC has one or two independent RLC entities for each RB in order to guarantee the QoS of the RB. In order to guarantee various QoSs, three operation modes, i.e., a Transparent Mode (TM), an Unacknowledged Mode (UM), and an Acknowledged Mode (AM), are provided. In addition, the RLC is responsible for adjustment of a data size to suit data transmission over an air interface and is responsible for segmentation and concatenation of data received from a higher layer[1,2].

1 The relationship between the wireless network andwireless link

The A cell, on which a general UE cannot camp in order to enable a network manager to utilize the cell for a special purpose, is referred to as a reserved cell and the other cells are referred to as non-reserved cells. In the cell selection process and the cell reselection process, the UE does not regard the barred cell as a selectable cell. The UE regards a non-barred cell or a non-reserved cell as a selectable cell.[3]

A suitable cell refers to a cell in which the UE can receive a public-use service. A suitable cell is a non-barred cell in which the intensity of a signal measured by the UE is greater than the intensity of a signal of a cell, which currently provides a service to the UE, by a predetermined value, which belongs to a Public Land Mobile Network (PLMN) which can be accessed by the UE, and in which a location area updating process or a tracking area updating process of the UE is not inhibited.[4]

From the viewpoint of the UE which uses a plurality of frequencies as in the dual cell HSDPA, the

cell includes one downlink and one uplink associated therewith. However, in the system using the plurality of frequencies, the cell does not always include one uplink and one downlink. The UE may include two downlinks or four downlinks and one uplink. In this case, a downlink without an uplink associated therewith may be present. That is, a cell including only downlinks or a cell including uplinks may be present.[5]

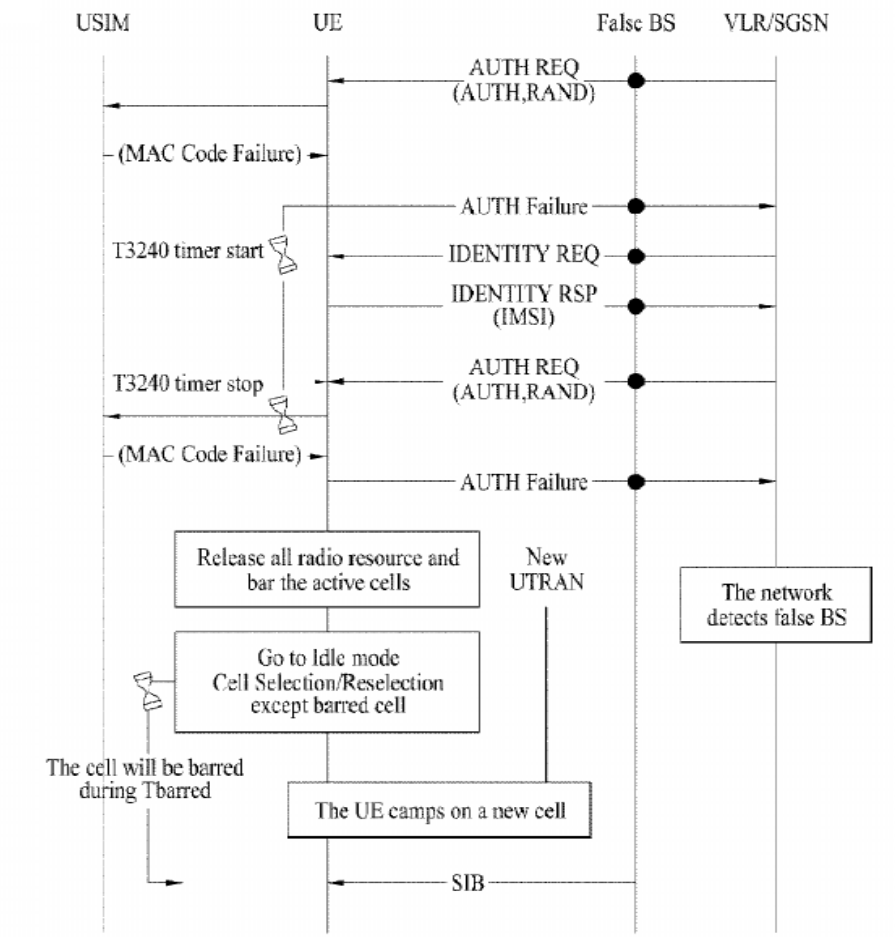

FIG. 1

Next, the active set will be described with reference to FIG. 1.

A radio link is a logical relationship between one UE and one network apparatus.

A downlink radio link is identified by a frequency and a cell identifier, and the frequency is at least one of a Universal Mobile Telecommunications system (UMTS) Terrestrial Radio Access (UTRA) Absolute Radio Frequency Channel Number (UARFCN) and an Evolved Absolute Radio Frequency Channel Number (EARFCN), and the cell identifier is at least one of a Primary Scrambling Code (PSC) and a Physical Cell Identifier (PCI).

An uplink radio link is identified by a frequency and a cell identifier. The frequency is at least one of a UARFCN and an EARFCN which are uplink frequencies to transmit data through the uplink radio link. In the UMTS, the cell identifier is an uplink scrambling code or a Physical Random Access Channel (PRACH) scrambling code. In the LTE system, the cell is identified by a PCI and a Cell Radio Network Temporary Identifier (C-RNTI).

Alternatively, the uplink radio link may be identified by the frequency and the cell identifier of the downlink radio link to receive control information necessary for uplink transmission.

The active set refers to a set of radio links for performing a specific communication service between the UE and the network, and a cell present in the active set is a cell located in an area in which soft

handover is possible. Due to handover, during actual data transmission, data transmission may be performed through one or more radio links.

FIG. 1 is a diagram showing an E-DACH active set if a UE uses one frequency. The active set includes an active set for DCH transmission and an E-DCH active set for E-DCH transmission. The active set generally refers to an active set for DCH and E-DCH transmission. The E-DCH forms a pair with a HS-DSCH. For E-DCH transmission, the UE receives a grant through an E-AGCH and receives an ACK/NACK signal of the transmitted data through an E-HICH. If the UE can receive data using three radio links C1, C2 and C3 through the HS-DSCH, radio links C1 and C2 which can perform E-HICH reception are present and a radio link C1 through which the UE receives the E-AGCH is present, C1 and C2 are included in the active set of the UE and C3 are not included in the active set of the UE.

Diagram showing an E-DCH active set of a UE which performs dual cell HSDPA. If the UE uses a plurality of frequencies, a cell having both an uplink radio link and a downlink radio link is included in the active set, but a cell having only an uplink radio link or a downlink radio link is not included in the active set. The active set of the E-DCH transmission is a radio link to receive a downlink control signal for uplink transmission. Accordingly, when data transmission is performed using one uplink frequency and two downlink frequencies, the radio link may be set as shown in FIG. 8. In this case, downlink radio links for receiving the E-HICH are included in the active set and all the other radio links are not included in the active set.Next, a cell selection method according to an embodiment of the present invention will be described with reference to is a flowchart illustrating a cell selection method according to an embodiment of the present invention.

2 Design of wireless network and wireless link

In some instances, well-known structures and devices are omitted in order to avoid obscuring the concepts of the present invention and the important functions of the structures and devices are shown in block diagram form. The same reference numbers will be used throughout the drawings to refer to the same or like parts.In the following description, it is assumed that a terminal includes a mobile or fixed user end device such as a user equipment (UE) and a mobile station (MS), and a base station includes a node of a network end communicating with a terminal, such as a Node-B, an eNode B, and a base station.First, dual cell High Speed Packet Access (HSPA) will be described with reference to FIG. 3.is a diagram showing a dual cell HSPA.As shown in FIG. 3, in the related art, a UE transmitted an Enhanced Dedicated Channel (E-DCH) using one frequency. However, in the dual cell HSPA, the UE simultaneously transmits data using two frequencies such that data transfer rate increases to twice that of the related art. In the dual cell HSPA, the UE may transmit data at a maximum rate of 20 Mbps, and an operation for transmitting data using two frequencies by the UE is referred to as a dual cell E-DCH operation. In addition, even in a downlink, in the related art, the UE received a High Speed Downlink Shared Channel (HS-DSCH) using one frequency. However, in the dual cell HSPA, one UE receives data using two frequencies so as to double a data reception rate. In the dual cell HSPA, the UE may receive data at a maximum rate of 80 Mbps, and an operation for simultaneously receiving data using two frequencies is referred to as a dual cell HSDPA operation. One UE may simultaneously receive data using four frequencies so as to increase a data reception rate to four times that of the basic HS-DSCH. This is referred to as a four-carrier HSDPA operation.

A cell which receives a downlink control signal necessary for data transmission through a primary uplink frequency of a UE in a dual cell HSPA is referred to as a serving HS-DSCH cell or a primary serving HS-DSCH cell. In addition, cells other than the serving HS-DSCH cell among cells in which a UE receives data are referred to as secondary serving HS-DSCH cells. At this time, the

primary uplink frequency is an uplink frequency in which a HS-DPCCH channel for transmitting an acknowledgement/non-acknowledgement (ACK/NACK) of the received downlink data exists.

Next, Carrier Aggregation (CA) of an LTE-A system will be described with reference to is a diagram showing the CA of the LTE-A system.

3 Summary

A cell is a wireless network object for transmitting a broadcast message from one UTRAN access point to all UEs present in one specific area and is identified by a cell identifier. A cell, on which the UE camps, refers to a cell selected after a UE successfully completes a cell selection process and a cell reselection process.Next, a cell state and cell reservation will be described. The network identifies a cell state by a barred cell and a non-barred cell in order to control the cell selection process and the cell reselection process of the UE. The barred cell indicates a cell on which the UE cannot camp and the non-barred cell indicates a cell on which the UE can camp.

Keywords: real-time communication; resources scheduling; edge-coloring; low latency

Abstract. WIA-PA network is a kind of multi-hop wireless network, which is specially designed for industrial process automation control. It uses hybrid management pattern with star and mesh structure. Intra-cluster and inter-cluster communication is scheduled simultaneously based on TDMA as well as FDMA. In this paper, a real-time cluster resources scheduling strategy for WIA-PA networks is proposed and the specific algorithm is implemented by edge-coloring. Our algorithm combines with optimal routing mechanism and arranges the order of links reasonably, resulting in avoiding conflict and improving the original communication success rate. Furthermore, the algorithm makes full use of channel resources, which greatly reduces end-to-end delay. The performance analysis shows that our algorithm is close to optimal for WIA-PA networks. In addition, compared with RSCA algorithm, our algorithm has lower latency and higher network throughput.

Introduction

Due to the huge advantage over wired communication, wireless communication technology has been a hot spot in the field of industrial automation control. Wireless process automation system can save costs and reduce the difficulty of connection among devices, which is applied to the complex industrial environment. What's more, it is easy to be maintained and very flexible, which hence has a broad prospect [1]. However, because the wireless channel is sensitive to interference, the specific requirements of industrial control application bring some challenges to wireless networks, especially in terms of strict real-time, reliability, security, low power consumption and time synchronization. These issues must be solved urgently when wireless technology is applied to industrial process automation.

Based on the IEEE 802.15.4 standard, WIA-PA (Wireless Networks for Industrial Automation-Process Automation) is the wireless communication specification used for industrial process automation and accepted by IEC in 2008 [2], which became the second Wireless industry standard after Wireless HART. WIA-PA networks adopt layered hybrid organization, divided into star and mesh structure. In the star network, router devices, as the cluster head, gather the data information from field devices and forward to the gateway. With centralized management, the network manager manages the entire network by collecting information of all devices and issuing commands, and allocates time slots and channels to clusters in mesh network. which can ensure normal communication. It accesses channels randomly with TDMA/CSMA mechanism, and supports periodic or non-periodic communication loads. Besides, frequency hopping spread spectrum and automatic retransmission technology improves the reliability of networks. WIA-PA has 16 available physical channels in all. Intra-cluster communication uses the same channel only while inter-cluster communication can use either the same or different channels, but conflict avoidance must be concerned. In this paper, according to the need of real-time communication in WIA-PA networks, time slots and channels are arranged orderly for links between each cluster, greatly improving the network performance.

The rest of this paper is arranged as following: In Section II, WIA-PA network architecture and superframe is introduced, and the relate work is summarized. Our scheduling algorithm is proposed

and the scheduling result of a specific network is given in Section III. In Section IV, compared with RSCA, we evaluate the performance of our algorithm. Finally, this paper is concluded in Section V.

BACKGROUND AND RELATED WORK

A. WIA-PA network architecture

WIA-PA network architecture is shown in fig. 1, which combines star structure with mesh structure.

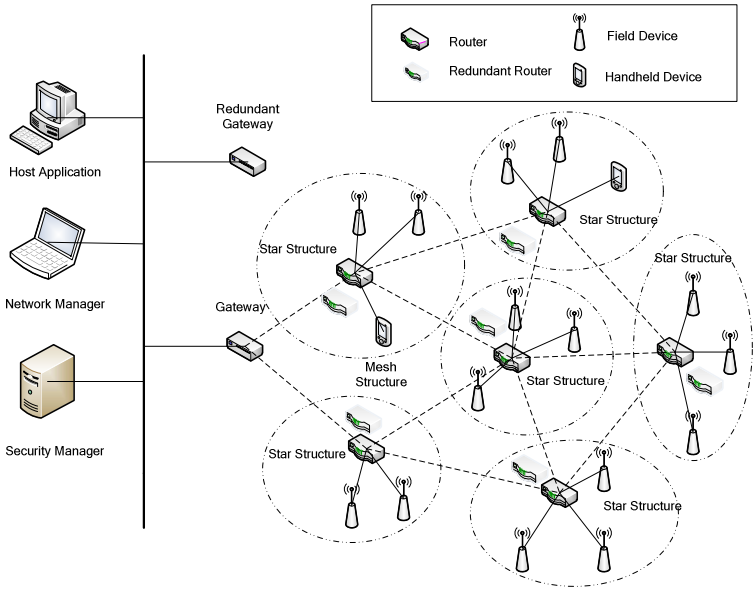

Fig. 1 WIA-PA network infrastructure

Routers, field devices and handheld devices constitute the star topology, regarded as a cluster. Field devices, as members of the cluster, collect data information and transmit to the cluster head. A handheld device is used to configure and diagnose the network. The reliable mesh network is composed of routing devices and the gateway. Routers transfer data information to the gateway which connects WIA-PA network with the upper management and application network. As the hinge, network manager is responsible for organizing the entire network, distributing communication tasks, establishing routing table and allotting communication resources. In addition, because cluster heads and the gateway may malfunction or die under very heavy loads, there are a large number of redundant equipments in WIA-PA networks, which can replace the dead nodes timely.

B. Superframe structure

WIA-PA networks coordinate communication between various devices through TDMA technology. Links are specified in time slots and channels, which ensure communication without conflict. Time synchronization is necessary among all devices.

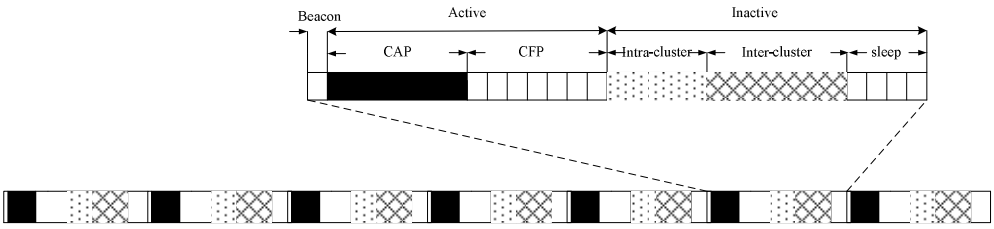

Fig. 2 WIA-PA superframe

WIA-PA superframe consists of cyclic time slots in fig. 2. The number of slots is the length of superframe. In order to facilitate the new devices joining, beacon frame is placed at the beginning of

each time slot. All routers send beacon frame through their own channel, while field devices can only receive beacon. New devices can get relevant network parameters from beacon. Next is active period, including CAP (Contention Access Period) and CFP (Contention Free Period). CAP is devoted to new devices joining, intra-cluster management and information retransmission. In CFP, communication between the cluster head and mobile devices is processed. Inactive period is used for intra-cluster and inter-cluster communication as well as sleep.

WIA-PA has rich network resources. Network manager is responsible for allocating resources to each device reasonably and the distribution result will affect the performance of network. There are two types of communication in WIA-PA networks. With intra-cluster communication, each member sends data information to the cluster head through the same channel in different time slots. Inter-cluster communication can be achieved through different channels, which also makes full use of network resources and reduces end-to-end delay. This paper mainly studies inter-cluster resource scheduling in WIA-PA networks, which assigns time slots and channels for each link in mesh network.

C. Relate work

Link scheduling strategies based on TDMA in wireless multi-hop networks have been widely researched [3,4], and many scholars propose a number of classic algorithms. However, to our knowledge, resources scheduling algorithms for WIA-PA networks are few. In [5], a cluster channel assignment strategy in WIA-PA networks is studied and a scheduling algorithm based on vertex-coloring is proposed, which can satisfy the demand of real-time communication. However its algorithm is too simple and reliability as well as throughput isn't considered. [6] describes an adaptive timeslot scheduling strategy for long cycle data in WIA-PA networks, which allocates resources for star and mesh network uniformly. Conflict is decreased owe to feedback mechanism, but isn't avoided completely. In [7], distributed and dynamic TDMA channel scheduling algorithm is presented, which reduces the channel interference by using blacklist technology. It also reduces data retransmission times effectively and improves the network throughput. [8] puts forward an improved adaptive channel hopping scheme in WIA-PA networks. The network reliability is greatly improved by the way of channel assessment and reasonable arrangement of channels sequence, but there are no specific optimization measures for network latency and network throughput is not evaluated either. In [9], a resources scheduling algorithm for multi-hop mesh networks is implemented by vertex-coloring. This algorithm avoids conflict, but the order of links is not arranged properly, leading to a high delay. In [10], a superframe scheduling algorithm for high reliability in Wireless HART networks is given. As a result of retransmission mechanism for each link, the network has a very high reliability, but the excessive consumption of network resources causes low throughput and high time-delay, which is not suitable for WIA-PA networks.

At present, most scheduling algorithms for wireless sensor networks are realized by graph theory, aimed at optimizing network performance. However, due to the special structure and application requirement of WIA-PA networks, few scheduling algorithms are satisfactory. According to the characteristics of WIA-PA networks, a resources assignment algorithm by edge-coloring is presented in this paper. Combining with optimal routing algorithm, we reasonably arrange the link order, which greatly improves the network performance.

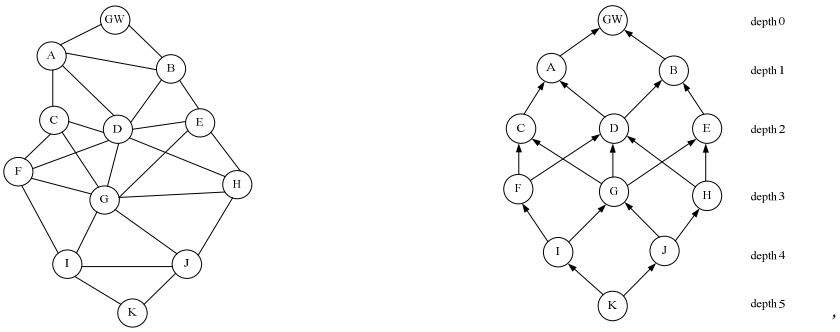
Resources Scheduling

A. Network model and definitions

Here we only consider cluster heads and gateway nodes in mesh network which can be modeled as a simple acyclic graph G = (V, E). V = {v0,v1,v2,…,vn} is the set of all nodes, where each node vi, $1 \le i \le n$, denotes a routing device and v0 is the gateway. E = {e0,e1,e2,…,em} is the set of all links, and the link ek = (vi, vj), $0 \le k \le m$, $0 \le i \le n$, $0 \le j \le n$, can be built if and only if vi and vj are in the range of

communication between each other. The set of time slots is defined as T = {t1, t2, t3,... , tl}, and the frame length is l. A kind of color corresponds to a time slot, which can be defined as S = T. Channel set is C = {c1,c2,c3,…,cr}. Scheduling issue can be regarded as assigning links to the plane composed by l slots and r channels.

In a real network environment, it is very necessary to create an optimal network topology and remove suboptimal links for network manager. If network nodes route packets through the shortest path, the network delay and power consumption can be reduced. In [9], the optimization method for mesh networks based on breadth-first search is described.



(a)The original graph G (b)The optimized graph G'

Fig. 3 Network model

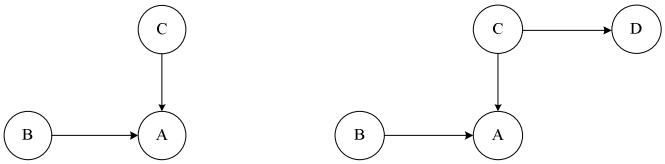
Fig. 3a illustrates an original network topology G and its optimized topology G' is drawn in fig. 3b. Uplink data is transferred from low-layer to high-layer gradually, so routing path of each node is the shortest. What's more, links between the children nodes and their uncle keep the network redundancy.

B. Scheduling algorithm

WIA-PA is applied in industrial process control, which requires real-time and reliability. Therefore, we consider the following strategies in our scheduling algorithm:

1) Based on graph routing. Graph routing contains multiple paths from the source to the destination. Data can be transmitted through other paths when a certain path is blocked. In order to ensure the fair communication opportunities of all devices and the redundancy of graph routing, resources should be allotted to each link. All links in the network graph are dyed with one colour at least.

2) Conflict avoidance. There are two types of conflict in WIA-PA networks: explicit conflict and implicit conflict.



(a)Explicit conflict (b)Implicit conflict

Fig. 4 Conflict in mesh network

As shown in fig. 4a, when the node B and C send packets to the node A at the same time, explicit conflict will appear. In order to avoid it, the links B->A and C->A should be assigned to different time slots. In fig. 4b, if the node A and C in the range of communication, and the node B communicates with A and meanwhile the node C send packets to D, then implicit conflict will occur in the node A.

We can allot the links B->A and C->D to different channels in the same time slot, which also ensures the utilization of network resources. Therefore, with the purpose of conflict avoidance, links with public node must be dyed in different colors while others can be dyed with the same color which should be arranged to different channels.

3) Reasonable links sequence. The sequence of time slots in a superframe corresponds to the order of communication, which will affect the communication latency greatly. A node should be arranged for the transmission slot as soon as possible to transfer packet when it receives a packet, which also saves the storage space of devices. Furthermore, due to real-time communication in WIA-PA networks, an edge can be colored only when its starting point has memorized received packets.

4) Optimal routing mechanism. Our resources allocation strategy combines with optimal routing algorithm. Data packets will be transferred through the best route preferentially, so links on the best route should be allocated in earlier time slots. In other words, they must be colored firstly. Here we selected a WIA-PA network oriented routing algorithm ORBV in [11], which has low latency and energy consumption.

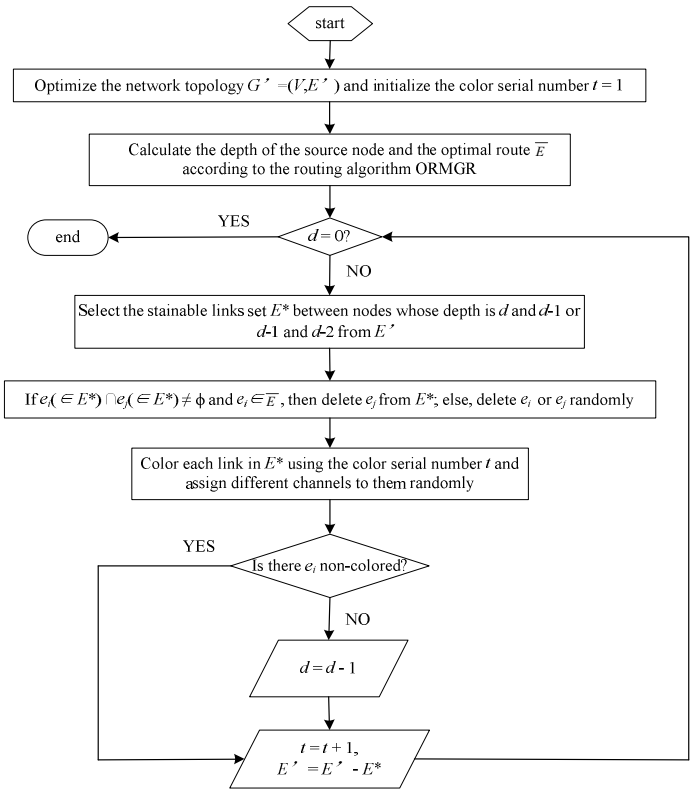


Fig. 5 Our scheduling algorithm

Our algorithm is implemented by edge-coloring which starts from the source node. An edge denotes a link and each color corresponds to a time slot. The specific scheduling algorithm is shown in fig. 5, where d is the network layer number and ei represents a link between the current layer and the upper.

C. Resources allocation

In accordance with our algorithm, the scheduling result of the graph G' in fig. 3b is showed in fig. 6. We assume that the optimal route is K->I->G->C->A->GW according to the routing algorithm ORBV.

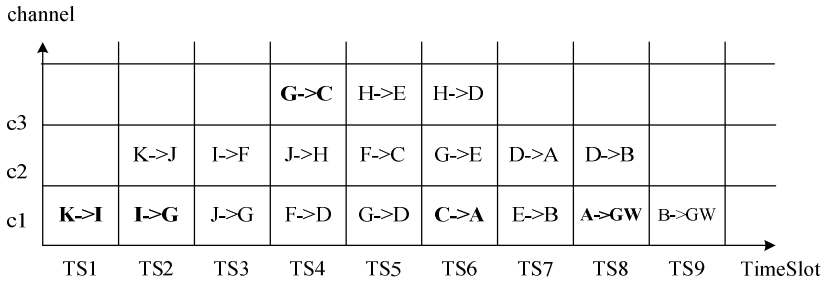

Fig. 6 The example of our scheduling result

We assign resources for each link in the mesh network, which guarantees the redundancy. In every time slot, any node appears at most once and all links are arranged to different channels, so as to avoid conflict completely. Moreover, we arrange links orderly and allocate the earliest time slots to links on the best route. For example, when the node K sends packets to the gateway, the links K->I at TS1, I->G at TS2, G->C at TS4, C->A at TS6 and A->GW at TS8 are used firstly.

Analysis and Evaluation

Our resources allocation strategy reasonably arranges time slots and channels for each link in the mesh network, resulting in conflict avoidance. Furthermore, considering limited buffer memory resources of devices, we arrange a transmission slot to the node immediately when it has received packets. The maximum of packets in each node is less than the number of its children. It can save the cost of devices and meet the requirements of industrial application.

In order to evaluate our strategy entirely, a route-based scheduling algorithm in wireless multi-hop mesh networks for collision avoidance (RSCA) proposed in [9] is compared with our scheduling algorithm. Its superframe result of the network graph G' in fig. 3b is presented in fig. 7. RSCA algorithm assigns communication resources to nodes in mesh network by the way of vertex-coloring which avoids conflict completely, but it does not arrange links orderly.

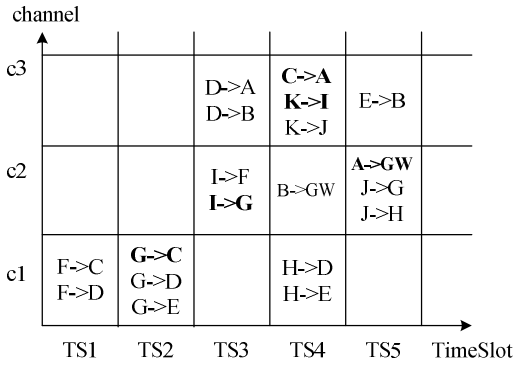

Fig. 7 The example of RSCA scheduling result

Our algorithm is based on graph routing, which rich redundant paths exist in the mesh network. Compared with multi-path routing, graph routing can effectively improve the robustness of the network [10]. Besides, because the transmission success rate on the optimal route is higher than that of other routes, the original communication success rate is greatly improved as a result of scheduling links on the optimal route preferentially. We assume that the loss probability of packets for each hop on the best route is pl = 0.05 and that on other routes is pl' = 0.1. Then the transmission success rate of our scheme shown in fig. 6 is 89.44%, which can ensure successful communication between the source and the gateway through a superframe. While RSCA arranges links with the common start to the same channel, leading to random links sequence for communication, so its transmission success rate is obviously lower than ours.

WIA-PA is applied in industrial process control which needs real-time communication. Our scheduling scheme decreases the transmission delay substantially because links are arranged in order and channel resources are made full use. In fig. 6, it takes eight or nine time slots to transfer data to the gateway from node K according to our algorithm. For RSCA algorithm shown in fig. 7, the shortest time is nine time slots, which the corresponding route is K->J->G->D->B->GW. However, in the practical application environment, wireless channel interference is generally strong. As mentioned before, our schedule has very high reliability and can guarantee successful communication through a frame. While RSCA algorithm can't ensure successful transmission through the fastest path from the source to the destination, which often requires several superframe cycle scheduling, so the network delay is very high. In addition, owe to optimal routing mechanism, our algorithm greatly improves the success rate of original communication, which also reduces the retransmission delay.

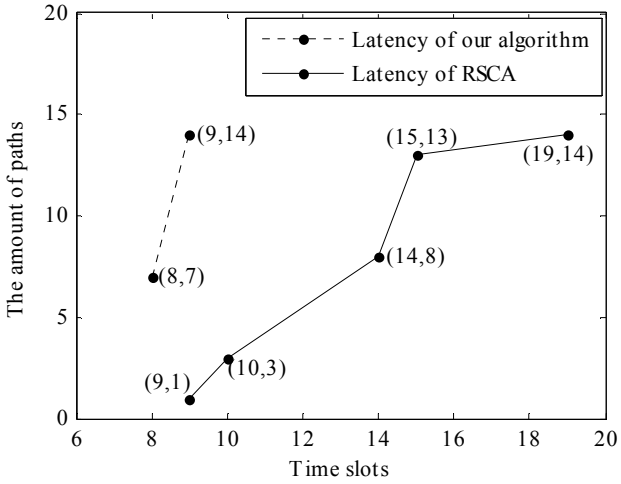

Fig. 8 The relationship between network latency and redundancy

There are 14 paths from node K to the gateway in fig. 3b. It's obvious that the network reliability is proportional to the amount of available paths from the source to the gateway which corresponds to redundancy. The relationship between network latency and redundancy is illustrated in fig. 8. The horizontal axis represents the total slots spent by transmission from node K and the gateway. And the vertical axis is the amount of homologous available paths. We can see that our algorithm has much lower latency than RSCA on the premise of the same redundancy.

Network throughput is also an important performance for WIA-PA, which is defined as the average number of packets received successfully by the gateway in each time slot. It can be expressed as following,

$$NT = \frac{n - n_l}{l}$$

Where n is the number of packets sent by all nodes in a superframe, n_l is the amount of loss packets in a superframe and l is the amount of time slots. For a specific network, n_l is fixed. However, the loss probability of packets with our strategy is lower than that of RSCA, so n_l of our scheme is smaller. In fig.6, our superframe length is 9 and node K can transfer data packet to the gateway through a superframe. While a successful communication between node K and the gateway needs twice superframe scheduling at least for RSCA in fig.7, which the total slots is 10. Thus, our algorithm improves the network throughput compared with RSCA. For the practical WIA-PA network, when cluster heads transmit data packets simultaneously, we can schedule their superframe at the same time by using channels parallelly which can achieve a high convergence speed. It's our future work.

Conclusion

A cluster resources scheduling algorithm for WIA-PA networks is implemented by edge-coloring in this paper. Communication resources are assigned to each link reasonably, which makes conflict avoidance. Based on graph routing, our strategy combines with optimal routing algorithm ORBV, which improves the success rate of original data transmission. Analysis shows that our algorithm improves the reliability and network throughput effectively, and save the storage resources of network devices. Compared with RSCA, our algorithm has lower latency and can satisfy the requirement of real-time communication in WIA-PA networks.

Research on Security Issues of the Internet of Things

Xiaofeng Wang

Langfang Teachers University, Mathematical and Information Sciences Institute, Langfang, China

Wangxiaofeng7654@126.com

Keywords: the Internet of things; information security; security policy; privacy protection

Abstract. According to the current mainstream architecture of the Internet of Things, Makes research on security threat of the Internet of things from the perception layer, network layer and application layer, Gives the corresponding security policies and measures. It provides the theoretical reference for security of the Internet of things and privacy protection.

Introduction

In recent years, with the rapid development of Internet technology and a variety of network access and intelligent computing, the Internet of Things as a new technology is being more and more concerned by people, and continues to be applied and promoted in all walks of life. The Internet of things connects the reality physical space and virtual information space, Its ubiquitous data awareness, information transmission based on wireless, intelligent information processing, can be used in all aspects of daily life, it is closely related to the national security and economic security, and has become an important factor of the competition of comprehensive national strength among countries. With the continuous development and application of the Internet of things, its own hidden security problems increasingly appear.

The Architecture of the Internet of Things

The Internet of things is a network based on the Internet, through the radio frequency identification (RFID), infrared sensors, global positioning systems, laser scanners and other information sensing device, according to the agreed protocol, connects anything with the Internet, to exchange information and communicate, to achieve intelligent identify, locate, track, monitor and manage . The Internet of Things architecture can be divided into three layers: the perception layer, network layer and application layer. It is shown in Fig. 1.

The Perception Layer. In the overall structure of the Internet of things, the perception layer exists as a basis, has a very important role. The perception layer is the beginning of the Internet of Things overall structure, its main task is to collect and transmit the data. Data is collected by GPS, camera and other reader tools, and the data is transferred to the associated device by means of short-distance transmission technology, such as ZigBee, Bluetooth and other wireless technologies or industrial field bus technology, so the device can process the data.

The Network Layer. In the overall architecture of the Internet of things, the network layer is based on the Internet. The network layer generally transmits the collected data, plays a very important function in the overall system of the Internet of things. The network layer requires the Internet of good performance; however, the situation of today's Internet can not meet the demand of data transmission. So, if we want the Internet of Things deeper and more long-term development, we need to re-integrate the current Internet, to improve performance.

The Application Layer. The ultimate aim of the Internet of things is to develop applications. Therefore, the application layer is the core of the Internet of things architecture .The application layer receives the data of collection and transmission, and then processes data through certain techniques, in order to have the right judge and control for the Internet of things. The Internet of things application

layer can be divided into the terminal device layer and application layer, which together take up the work of the Internet of things in different industries and different areas.

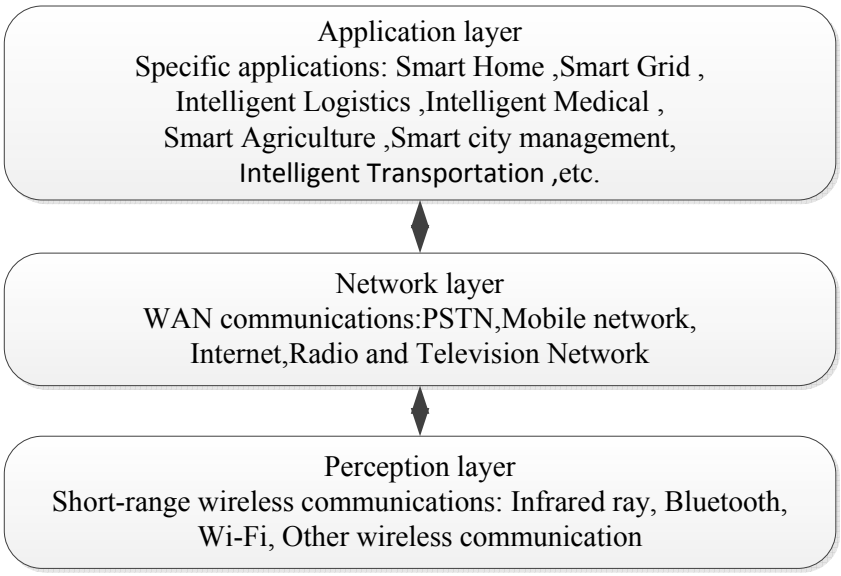

Fig. 1. The Architecture of the Internet of Things

Security Threats and Countermeasures of the Internet of Things

Perception Layer Security Threats. It is mainly related to RFID security, sensor nodes security, and intelligent terminal security.

Denial of Service: electronic tags respond to a lot of malicious requests without differentiate, resulting in not responding to legitimate requests. Safety measures: use intrusion detection techniques to identify attacks.

Node Failures: due to the destruction of the environment or the physical, leading to the perception node failure, resulting in inaccurate data, or even false data. Safety Measures: use the fault detection and tolerance techniques.

Message Damage: intruder between the source node and the destination to insert itself, tampering message content. Safety measures: use lightweight or super lightweight encryption and authentication mechanisms.

Physical Damage: sensor nodes are in the unattended state may be damaged or stolen. Safety measures: establish a remote device management platform for sensor nodes to monitor and manage.

User Privacy Violations: sensor nodes transmit information stored indiscriminately to the reader. Safety Measures: Since node computing and storage capacity constraints, can use lightweight or super lightweight encryption and authentication techniques.

Packet Loss: at the sensor network aggregation node, due to the large amount of data, is prone to channel error, the node congestion, and packet loss and packet collisions. Safety measures: use data fusion and security control techniques to improve fault tolerance of the network.

Node Camouflage: the perception layer nodes and devices are typically deployed in an open environment, the attacker obtains node identity information through the analysis of node, and then captures the nodes, masquerading as legitimate users; or posing by using other nodes. Safety measures: use access control technology for sensor nodes to verify the legality of the node.

Channel Interference: radio frequency signals and wireless network are vulnerable to interference, the attacker can issue a large number of repeat visit request, leading to the depletion of energy of active tags or the gathering node of gateway type is submerged, blocked, so that the work of the perception layer becomes failure. Safety measures: use electrostatic shielding, active jamming, and blocking labeling technology to protect the communication channel.

Information Theft: Since sensor nodes computing and storage capacity limits, unauthorized RFID reader communicates with the label directly, read, tamper or delete data. Safety measures: use lightweight access authentication control; allow only certified reader to access the label.

Security Threats and Countermeasures of the Network Layer. Network layer security issues are mainly related to transport security for wireless sensor networks, mobile communications networks, the Internet, private network and other networks, and secure issues of heterogeneous networks.

Routing Attacks: selective delivery attacks and false network routing attacks cause waste of resources and changing of the routing path or circuit. Safety measures: use secure routing protocols, routing information authentication, intrusion detection, etc.

Middle Attack: The attacker posing as an intermediate node, destruct information confidentiality, integrity and availability. Safety measures: use encryption and authentication measures to protect the network.

Information Tampering: data transmitted over the network is vulnerable to tampering. Safety Measures: use the message authentication technologies, such as digital summaries integrity protection technology.

Replay Attacks: an attacker sends a packet has been received over, to achieve the purpose of deceiving the system. Safety measures: use the time stamp, serial number, and response mechanisms to prevent replay attacks.

Across Heterogeneous Network Attacks: network interconnection of different protocols and different security domains can cause serious safety problems, such as cross-border two-way attacks, protocol conversion reliability, disclosure of sensitive information and so on. Safety measures: divide security domain, protocol conversion, isolation protocols, information ferry and other technical measures.

General Protocol Attacks: SYN Flood, ARP Spoof, Ping of Death, IP fragment and other network attacks may make the network device or transmission network in response to a service request rejected. Safety measures: enable the appropriate security module on the network devices such as intrusion prevention, packet filtering to block these conventional network attacks.

Information Disclosure: the attackers obtain confidential information, such as user privacy information on unencrypted network. Safety measures: use VPN, TLS and other security technology to protect the confidentiality of information.

Transmission Performance is Limited: node scale becomes larger, sends large amounts of data, and then lead to network congestion, resulting in intolerable delays or even denial of service. Safety measures: use data fusion and intelligent processing technology to reduce network redundant data.

Security Threats and Countermeasures of the Application Layer. Mainly related to the terminal application layer security, data confidentiality, integrity, availability, Auditability and application systems own security.

Information Disclosure: disclosure of confidential or private information in the data processing, transmission and storage. Safety measures: use encryption technology to ensure confidentiality of data transmission, processing and storage.

Access Control Vulnerabilities: access control logic confusion or control failure, may lead to serious security problems. Safety measures: use discretionary access control, mandatory access control, role-based access control, attribute-based access control policy.

Software Vulnerabilities: memory leaks, buffer overflows, SQL injection, XSS injection and other application vulnerabilities are seriously affecting the safe operation of the system. Safety measures: In software design, use technologies to avoid security loopholes. Before the on-line operation, should carry out the vulnerability scan.

Security Audit Vulnerabilities: security audit functions miss, don't audit important security event, auditing data protection is improper and so on. They may make potential or occurred security incidents not be effectively tracked. Safety measures: improve security audit function; allow users to be responsible for their actions.

Integrity Destruction: data is modified, inserted, deleted, etc. in the processing, transmission and storage. Safety measures: use cryptographic technique and hashing technology to protect data integrity.

Denial of Service: When a large-scale concurrent access, low hardware configuration or software design flaws can lead to system response slow or even denial of service. Safety measures: the application of the Internet of things should be considered in the performance and capacity of the system to avoid performance bottlenecks. Before on-line operation, the performance of stress tests should be carried out.

Insecure Terminals: mobile operating terminal and PC have not security reinforcing, security scanning, may pose security vulnerability. Safety measures: carry out terminal security checks, security certification, and prevent illegal end user to use system.

Summary

Currently the Internet of things has started preliminary development and pilot, but security and privacy protection of the Internet of things is one of the decisive factors that determine the rapid development of the Internet of things. From the three-layer structure of the Internet of things, analyzes the security threats of the Internet of things, and gives solutions, at today of the rapid development of the Internet of things, hope to provide help for the country's development and construction of the Internet of things and protect our security of the Internet of things and national security.

Research on Network Control Based on QoS of the Network

ZHOU Yang[1, a]

[1]Beijing University of Posts and Telecommunications International School, Beijing 102209,China

[a]ZhouYang2015@yeah.net

Keywords: network control, QoS, controller

Abstract. With the technology improvement of computer communication and multimedia coding, real time communication such as audio and video is introduced to networks and become a dominant way of communication. In the control of network, the optimization problem of the network controller based on network Quality of service (QoS) is a very important problem in the research of network control. Considering the influence of network quality—of service(QoS)on the control performance，a system model combining the network parameters and the control parameters is established for networked control systems(NCSs). Based on this, the condition dependent on the network parameters and control parameters is presented for the existence of guaranteed cost controllers. LMI). Within the scope of QoS perturbation，the designed controller can not only make the system as hypnotically stable but also guarantee that the system performance index is not greater than the upper bound.

1.The brief introduction of QoS.

As the name suggests, the Quality of Service often reflects the consumer's satisfaction with the services provided by servers. In computer systems, especially the Computer Network System, as a provider of calculation and information services also has the same quality problems of quality of service (QoS). From the appearance of computer system, people are tirelessly focused on working to improve service performance and service quality of the system. For present, definition of the QoS has a various forms. We see from chart 1 that RFC2386 describes QoS as: network needs to meet a series of service requests in data transmission flow, such as bandwidth, delay, delay jitter, drop rate, throughput and complexity etc. QoS reflects the ability of network in guaranteeing information transmission and meeting the services.

Types of application	Requirements for QoS	Range
FTP	bandwidth	0.2-10Mbps
Telnet	Relevant delay	<=800ms
Telephone	bandwidth	16kbs
	End-end delay	0-150ms
	End-end jitter	1ms
	Drop rate	<=le-2
HDTV	bandwidth	>=1Gbps
		500Mbps
		20Mbps
	End-end delay	250ms
	End-end jitter	1ms
	Drop rate	<=le-2
		<=le-11

Chart 1:QoS requirements of several applications

Quality of Service (QoS) is a set of service requirements, which the network must meet these requirements in order to ensure the appropriate service level of the data transfer. QoS draws a distinction between the business flow and customizes different strategies through various kinds of ways in the process of data transmission in the network, such as immediate sending, sending later,

discarding the different strategies to protect different quality service requirements of the data of different priority level .

2.Network control system.

The improvement of the performance of the network control depends not only on the algorithm design but also closely related to the shared network transmission resource scheduling. Scheduling problem of network control is based on transfer order assigned by the transmission scheduling algorithm for each entity (such as sensors, controllers and actuators, etc). Scheduling algorithm is actually a series of rules which decides the delivery order.

2.1Intrduction of the network control system.

In the network control system, we assume that the controlled object is a invariant continuous system, which can be described as:

$x(t)=Ax(t)+Bu(t)$ (1)

$y(t)=Cx(t)$ (2)

$x(t)\in R^n$ and $u(t)\in R^m$ is the state vector and controlled input vector respectively. A and B is constant. Assume that the sensor is clock-driven; controller and actuator are event-driven and single packet transmission. Data type (1) maintains and realizes the real control input must be piecewise continuous function by the zero order. In addition, considering network latency and packet loss in the process of network control, the actual network control system can be expressed as:

$x(t)=Ax(t)+Bu(t), t\in(i_kh+T_k, i_k+_1h+T_k+1)$ (3)

$u(t+)=Kx(t), \quad t\in(i_kh+T_k, k=1,2\cdots)$ (4)

H is the sampling period, K is feedback gain for the network controller, i_k (k=1, 2,...) are integers, T_k is network induced delay which shows the time interval needed from the time when sensor samples from the control object to the time when controller sends controlling signal to the actuator.

2.2QoS and network controller.

At present, research about controller design method based on the Network Quality of service (QoS) mainly focuses on two aspects: (1) according to the QoS parameters measured online to dynamically adjust the output of the controller gain; (2) to complete collaborative design of controller along with QoS in the design phase of Network control systems. The two methods are consisten twith respect to their esence, which dynamically adjust the output of the controller gainis according to off-line table controller gain parameters under different Network QoS and Network QoS.

Under the network environment, the joint control of network parameters and parameters of the control system can be described as the following general form:

$x(t)=f(x(t)),u(t),p_{x(t)},g(QoS)$ (5)

$x(t)=y(t),t\in[-d,0]$ (6)

$x(t)\in R$ ， $u(t)\in R^m$ are state vector and controlled input vector respectively, $p_{x(t)}\in R^m$ is object parameters from remote control, and quality of service (QoS) is related parameters about network services, $f\in R^m$ is conversion function of the network system, d is network system delay and (t) is the system initial state functions. Further, if the sensor system is time-driven, controllers and actuators are the event-driven, single packet transmission and the system state data are fully measurable, the state feedback controller output u (t) maintains and realizes through the zero order and discretization, then type (5) and type (6) can be described as:

$x(k+1)=f(s(k)),Kx(k-tik),px(k),y(QoS)$ (7)

And ik(k=1,2…) and are integers.

2.3Network service quality of real-time data .

From chart 1 we see that the network control system has more than more one network node and the sending node pi. In addition, according to business characteristics of network control system,

its data mainly divided into two categories: (1) real-time data with periodicity; 2) non real-time data amd non-periodicity mainly the control parameters' setting, the switch command and data report forms etc. For not the real-time data can go with dynamic input bandwidth scheduling according to the network quality of service and using "breakpoint continuingly" network technologies.

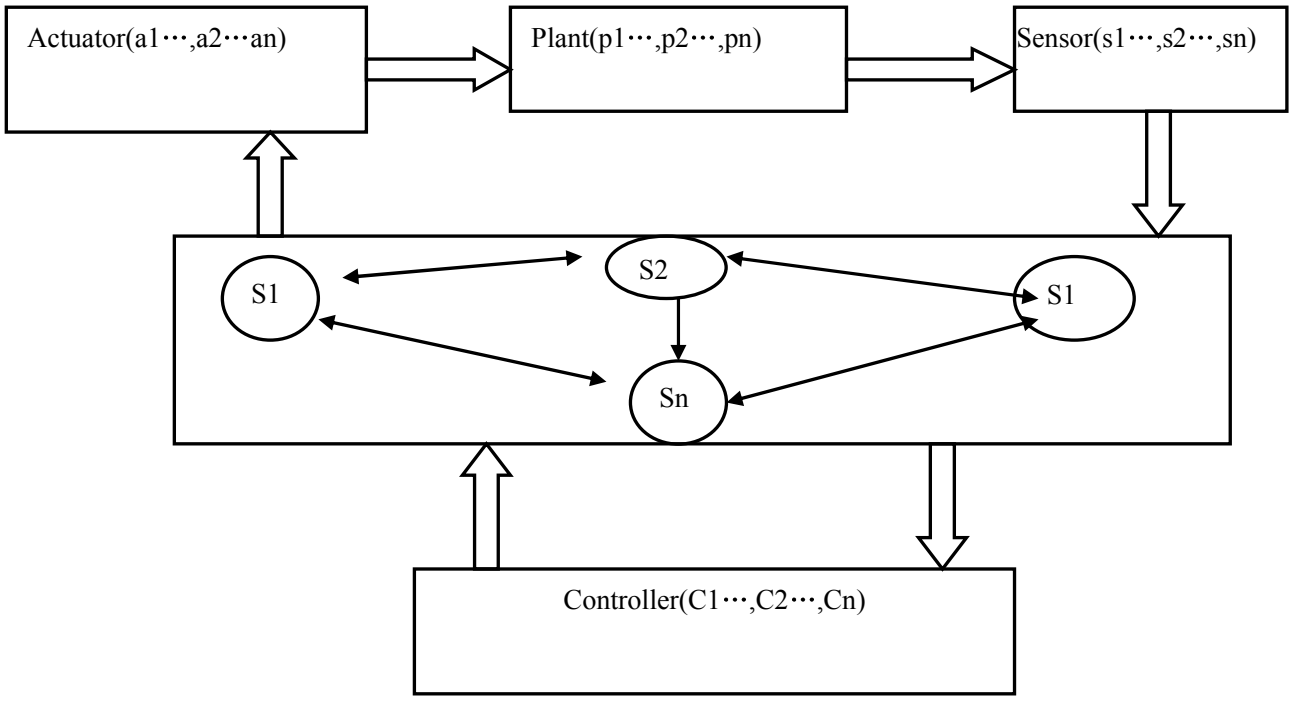

Chart 1: Network control system

3.**Numerical simulatin.**

From chart 2 we can see that with the change of the network parameters, the performance of the closed-loop system will decline, this is because different loop network parameters and control system can lead to a drop in the quality of network service and affect the performance of the closed-loop system. the Network controller design method based on the network quality of service gives the regulation of network parameters and control with the change of system parameters on the control system performance attenuation, and can provide certain theory basis for further network scheduling.

T(s)	P(k)	C(kbps)	£(kbps)	J	K
0.8	8	10	[0.1,8]	20.1655	[-1.461,-1.3395]
0.75	8.5	9.8	[0.1,8]	39.8903	[-1.8903,-1.7037]

Chart 2: Numerical simulation

Summary.

In network control problem, the collaborative problem of control and scheduling is mainly aimed at choosing the appropriate signal transmission network and designing a suitable controller according to control performance requirements. In the network, selected cases are external disturbances and network QoS is time-varying. If with the same controller gain to deal with the time-varying network control, the control performance will become worse. So according to the network QoS parameters such as transmission delay, combining network controller design and network scheduling, effective measures are taken to improve the comprehensive performance of the network control. The research questions are interaction design and scheduling of many objects of network controller and network QoS, and network quantitative and robust controller design etc.

Keywords: Computer cluster; Load balancing; Oscillating; Adaptive

Abstract. Currently it is difficult to use a single network computer application server to meet the demand of concurrent access to a large number of users. It is an ideal way to introduce in the cluster technology in the network for a computer system to solve this problem. In this paper, network computer server cluster on the basis of the existing network computer system is designed and key issues are studied.

Network computer system

With the development of computing technology, personal computing provides users with an increasingly rich personalized graphics interface and application, but costs of personal computer installation, deployment, maintenance and management continue to increase, the PC calculation mode put forward a huge challenge for users, especially for business users. Network computer system not only allows the user to use the applications and personalized settings of the server by service agreement, but also allows multiple users to share the application computing and storage resources, thus greatly reduces the installation, deployment, maintenance and management costs. The calculation mode that provides users with remote service network computer through network computer is becoming increasingly popular; its products are increasingly rich.

Basic principle

The so-called network computer system generally consists of three parts: the application server, the client and the application service agreement. The design of the application service agreement is the core of the network computer system. The application of the service agreement here refers to the mechanism of interaction between the client and server in particular. In network computer systems, multiple clients communicate with the server system through application service agreement thus be able to shared server the application service. Application logic, including window systems are running on the server side, the client only has a simple input and output capacity. Compared with the traditional mode of application, application mode based on network computer system has some typical features.

ASPNC

ASPNC system is the foundation of this article. The system is for different applications, such as the electronic government affairs, network education, financial services and software factory. With the support of all kinds of application server, it provides high cost performance, convenient solution that easy to use. Multiple users can use a variety of clients through the network to access application server and the X window system under various applications, such as office software and Internet software, etc that remote operation application server provides. In more advanced cases, the client's external equipment can automatically register as a server operating system peripherals, making the client an advanced network terminal. The application of the system model is shown in figure 1.

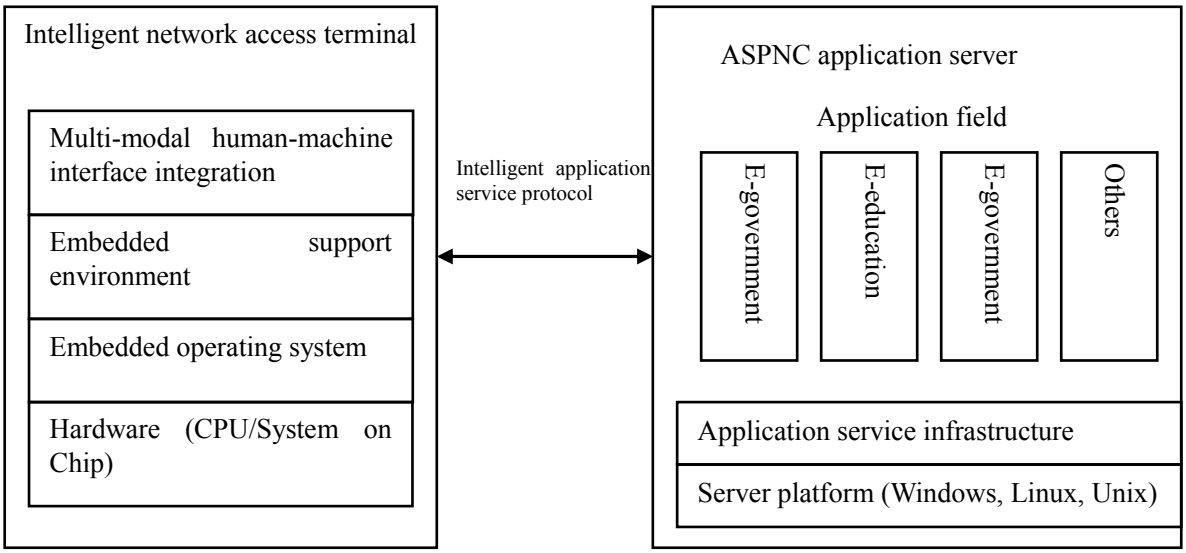

Fig1. ASPNC application mode

This paper will introduce the system from two aspects of application service protocol and system architecture.

Intelligent application service protocol (IASP)

Intelligent application service agreement (hereinafter referred to as the IASP) is the core content of ASPNC system. IASP protocol sequence consists of two parts: initialization protocol handshake and message content delivery phase. In initial handshake agreement, negotiations at the ends of the client and the server is initialized, specific work are as follows: protocol version number consultation, certification, session management, information, graphics configuration system, terminal initialization messages and server initialization. When it is in the message content it is transmitted in accordance with the input and output content categories of the transmission.

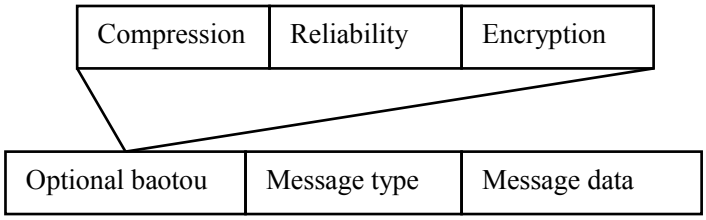

Fig2. IASP protocol message format

IASP agreement is as shown in figure 3, including four sub-protocols: user interface protocol, input information protocol, parameter control protocol and voice transmission protocol.

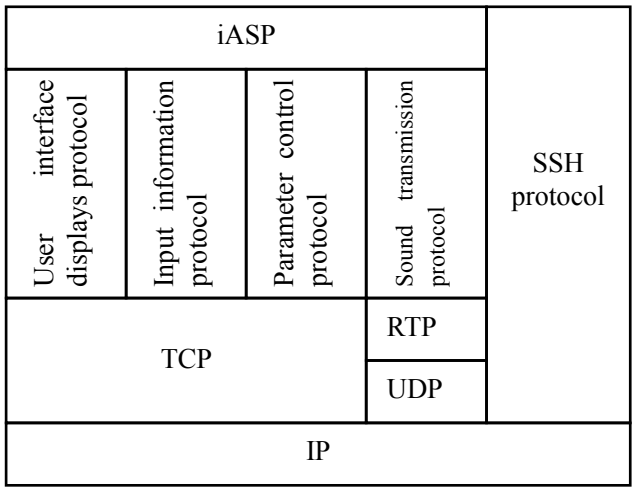

Fig3.IASP agreement

ASPNC architecture of the system

Structural view of the system structure that can only access network terminal system about IASP protocol can be abstractly divided into two key parts: one part is for processing the system input and output data on the server; output data gotten in application system will be stored in the data buffer, or input data in protocol processing engine from the client application transmitted to the system. On the client side, this section will export output data from protocol processing engine in the corresponding client module, or get the keyboard and mouse input information and then transmits it to the protocol processing engine. Another key part is for protocol processing engine, this section transmit input and output data according to certain data encoding format and strategy on network transmission.

The algorithm based on the load weight

Calculation of node performance and load

Nodes in the cluster system $S=(S_1,S_2,...,S_n)$ is often heterogeneous, so task allocation must consider the performance of different nodes in order to achieve the effect of load balance. The performance $C(S_i)$ of the node S_i is mainly evaluated from CPU number n, frequency of CPU $C(C_i)$, memory capacity $C(M_i)$, rate $C(D_i)$ of disk I/O, network throughput $C(N_i)$ and other indicators, using the type (1) to calculate.

$$C(S_i)=k_1\times n\times C(C_i)+k_2\times C(M_1)+k_3\times C(D_i)+k_4\times C(N_i) \qquad i=0,1,...,n-1,\sum k=1 \qquad (1)$$

Load $L(S_i)$ of node S_i is mainly considered from the CPU utilization $L(C_i)$, memory utilization rate $L(M_i)$, utilization $L(D_i)$ of disk I/O, network bandwidth occupancy rate $L(N_i)$ and other indicators. Use formula (2) to calculate.

$$L(S_i)=k_1\times L(C_i)+k_2\times L(M_i)+k_3\times L(D_i)+k_4\times L(N_i) \qquad i=0,1,...,n-1,\sum k=1 \qquad (2)$$

Load weight and load difference

Node load weight $W(S_i)$ is defined as the ratio of node loads $L(S_i)$ with node properties $C(S_i)$, using type (3) to calculate. The greater the weight, the heavier node load is, according which task allocation may be determined according to the size of the load weight.

$$W(S_i)=L(S_i)/C(S_i) \qquad i=0,1,...,n-1 \qquad (3)$$

Node load difference $\Delta L(S_i)$ refers to minus the difference between it from the maximum load weight $W_{\max}$ of the node load weight and then the performance of the node, using type (4) to calculate.

$$\Delta L(S_i) = (W_{\max} - W(S_i)) \times C(S_i) \qquad i = 0,1,...,n-1 \tag{4}$$

Load incremental load nodes load and correction

Because the system is updated regularly, it is unable to get the actual load of each node the update cycle; we need to introduce the load increment to forecast the node load. Load incremental δ refers to the node load type brought by some kind of a request assigned. Type (5) is used to calculate. It is associated with the type of service request, so need to calculate load increment for the different service.

$$\delta = L(S)/n \tag{5}$$

Summary

Load balancing algorithm is the core part of load balancing cluster, excellent equalization algorithm can play the advantages of cluster, make full use of the resources of the cluster, to provide users with high quality service. By analyzing the advantages and disadvantages of the commonly used load balancing algorithm, this paper proposes a dynamic feedback load balancing algorithm based on the load weight, and the algorithm of the main features are: full application node the actual load and performance of two factors, the guidance task allocation, through the load correction to ensure system stability and the experimental results show that the arithmetic
Method can better improve the efficiency of equilibrium, to improve the stability of the load balance cluster.

Keywords: LEACH protocol; residual energy; density; distance

Abstract. In order to prolong the lifetime of wireless sensor networks, improvement of cluster-head selection mechanism based on LEACH protocol is proposed. To make the energy distribution more uniform, we consider the relationship of the density of nodes, residual energy of nodes and distance between nodes and Sink node. It eliminates the defect of energy consumption imbalance in the network caused by random position of cluster-heads and the problem of premature death of nodes caused by low energy nodes becoming cluster-heads. Simulation results show that compared with LEACH algorithm, the improved algorithm extend the network lifetime.

Introduction

A wireless sensor network is composed by a large number of cheap micro sensor nodes in the monitoring area, which is a multi-hop self-organization system by wireless communication method. Its purpose is to sense cooperatively, collect and process the sensing target information within coverage area and send it to the viewer. Due to the limited resources of a single node in wireless sensor networks, reducing energy consumption and prolonging the survival time of the network have become the primary purpose of wireless sensor networks routing protocol design. Routing protocols are divided into plane routing protocol and cluster-based routing protocol [1]. Common plane routing protocols include DD [2], SPIN [3], etc.. Plane routing protocols need to maintain a large number of routing table and take up large storage space, so it is not suitable for large-scale networks [4] [5]. Currently, cluster-based routing protocol for wireless sensor networks is the mainstream protocol, this paper analyzes the advantages and disadvantages of a representative cluster-based routing protocol-LEACH protocol, and proposes an improved routing protocol. The main goal is to balance the network load, and extend the network lifetime.

LEACH Protocol

Low Energy Adaptive Clustering Hierarchy(LEACH)is the first cluster-based routing protocol proposed by Heinzelman [6]. The basic idea of the protocol is to randomly select cluster-heads by means of circulating, and cluster-heads fuse the information from the nodes in the cluster, then the cluster-heads send the information to Sink node, which reduces the transmission capacity and data transmission distance, reduces the energy consumption of the network, and extends the network lifetime [7] [8].

Algorithm description. The cluster-head selection principle of LEACH algorithm is: a sensor node generates a random number between (0,1), if it is less than the threshold T (n), then this node is selected as the cluster-head node. T (n) is defined as:

$$T(n)=\begin{cases}\dfrac{p}{1-p*[r \bmod(1/p)]} & n\in G\\ 0 & otherwise\end{cases} \tag{1}$$

Where, p represents the percentage of cluster-heads, r refers to the current round, G denotes the collection of the nodes which have not been selected as cluster-head in the past 1/p rounds.

Analysis of algorithm. LEACH algorithm selects nodes randomly as cluster-heads to balance the whole network load. But the cluster-head selection is random, node with less energy may become a cluster-head, thus it may cause the depletion and premature death of node. The cluster- head distribution is not uniform, there may be a high density of nodes where no cluster-head or cluster-heads in the network edge, which increases the communication distance. It leads to increase the energy consumption and reduce the lifetime of the network greatly [9][10][11].In view of such defects, cluster-head selection mechanism should be improved. In order to prolong the network lifetime, the residual energy, density and location of the nodes must be considered when choosing a cluster-head.

Improvement of Cluster-head Selection Mechanism

Network model. In this paper, we use the node energy consumption model shown in Fig.1:

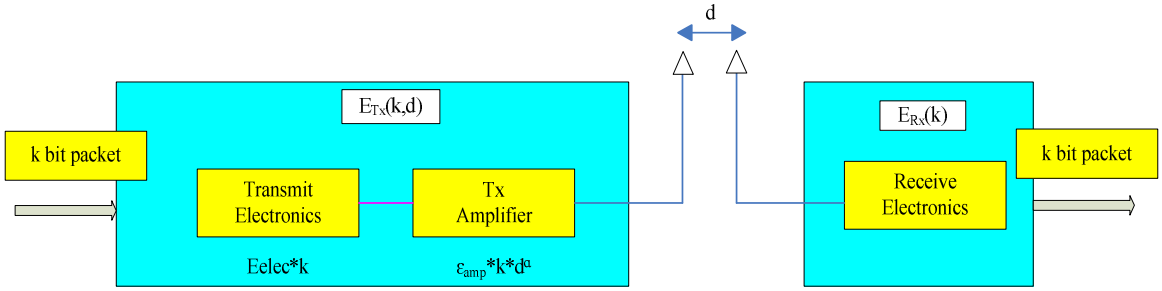

Fig.1 Node energy consumption model

The energy dissipation of the sensor nodes sending k bit data consists of two parts, one is used to produce signals, the other is used to amplify the signal. Energy is calculated by:

$$E_{Tx}(k,d) = E_{Tx_elec}(k) + E_{Tx_amp}(k,d) = \begin{cases} kE_{elec} + k\varepsilon_{fs}d^2, d < d_0 \\ kE_{elec} + k\varepsilon_{amp}d^4, d > d_0 \end{cases} \quad d_0 = \sqrt{\frac{\varepsilon_{fs}}{\varepsilon_{amp}}} \tag{2}$$

Eelec represents the circuit energy consumption, ε_{fs} and ε_{amp} are energy of the power amplifier magnification in the free space model and the model of multi-path fading, respectively.

The energy consumption of receiving k bits of data is given by:

$$E_{Rx}(k) = E_{Rx_elec}(k) = kE_{elec} \tag{3}$$

Cluster-head fuses the cluster membership information and its own data, and data fusion energy consumption is:

$$E_{fuse} = (I+1) * E_{DA} * k \tag{4}$$

I represents the node number of a cluster, E_{DA} is energy consumed by unit data fusion.

Definition. Neighbor nodes: the nodes that node i can communicate with directly in a hop range.

Node density: The number of neighbor nodes of node i.

Radius of investigation: $R = \sqrt{\frac{M}{p * N * \pi}}$, M represents the area of the detection region, p represents the probability of selected cluster-heads, N represents the number of nodes in the detection zone.

Improved of cluster-head selection mechanism.In LEACH algorithm, whether a node becomes cluster-head or not has something to do with the percentage of cluster-heads and whether the node has served as a cluster-head. It has nothing to do with node's residual energy, density and location. In the improved algorithm, the node's residual energy, density and location are considered as the threshold's impact factors. So it can increases the probability of the node becoming cluster-head which has more residual energy, greater density, shorter distance from Sink node . Improved threshold is defined as:

$$T(n) = \begin{cases} \frac{p}{1 - p*[r \bmod (1/p)]}[(\alpha \frac{E_{current}}{E}) + (\beta \frac{N(i)}{\pi R^2}) + ((1-\alpha-\beta)\frac{\overline{D_{i_\sin k}}}{D_{i_\sin k}})] & if\ n \in G \\ 0 & otherwise \end{cases} \tag{5}$$

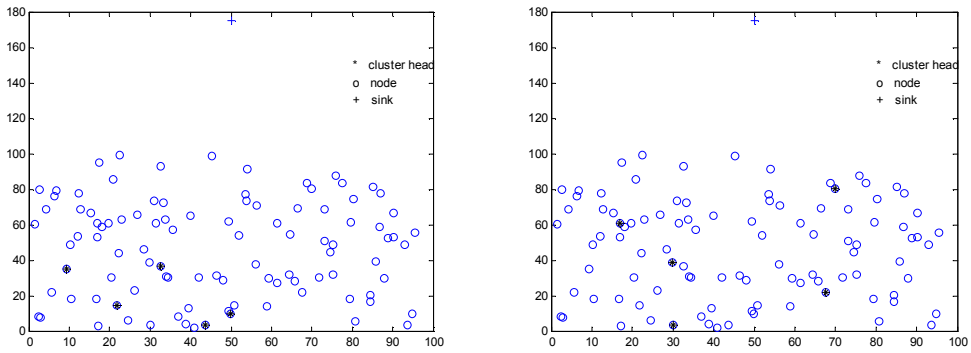
Where, p represents the percentage of cluster-heads in all nodes, r refers to the current round, G denotes the collection of the nodes which have not been selected as cluster-head in the past 1/p rounds. $E_{current}$ represents residual energy of the current node, E represents the initial energy of the node, N (i) represents the number of neighbor nodes of node i, R represents radius of investigation, D_{i_sink} indicates the distance between node i and Sink node, $\overline{D_{i_sink}}$ shows the average distance between i's neighbor nodes and the Sink node, α, β are weighting factors, respectively.

Simulation Results and Analysis

The energy consumption of the network is mainly used for data transmission, data reception and data fusion. The LEACH algorithm and the improved algorithm are compared by simulation using MATLAB in this paper. Parameters are set as: E=1J, monitoring area is 100m*100m, Sink node location is (50m,175m), E_{elec}=50/nJ(bit)$^{-1}$, ε_{fs}=10pJ/bit/m^4, ε_{amp}=0.0013nJ/bit/m^2 ,E_{DA}=5nJ.

Through simulation, we found that the best performance can be attained when the parameters are set as $\alpha = 0.6, \beta = 0.2$.

It can be seen from the simulation Fig.2 that the distribution of cluster-heads is more uniform in improve-LEACH protocol, which reduces the communication distance between nodes in the cluster and the cluster-head, so that the energy consumption is reduced.



(a)LEACH cluster-heads distribution (b)improve-LEACH cluster-heads distribution

Fig.2 LEACH protocol and improve-LEACH protocol cluster-heads distribution map

As we can see from Fig.3, the first node's death occurred in the 1580th round in improve-LEACH protocol, while 1377th round in LEACH protocol, that is, 15% delay than LEACH. The fiftieth node's death occurred in the 2245th round in improve-LEACH while 1680th round in LEACH protocol, which is 33% extend than LEACH. The reason why improve-LEACH is better than LEACH protocol lies in that when selecting a cluster-head, improve-LEACH protocol considers the residual energy of nodes, the density of nodes, and the distance between the node and the sink node, which ensure the optimal node is selected as the cluster-head so that the cluster distribution is more uniform, the energy load is more balanced.

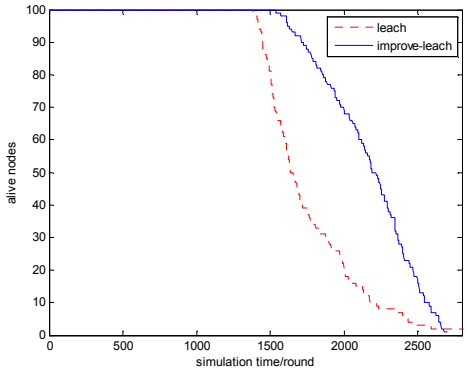


Fig.3 Relationship between survival nodes number and the simulation time

Conclusion

For the uneven distribution of nodes and random selection of cluster-heads and other defects of wireless sensor networks, this paper presents an improved cluster-head selection mechanism, that is, considering the residual energy of nodes, the density of nodes, and the distance between the node and the sink node when selecting a cluster-head, in order to solve the node load imbalance problem in LEACH algorithm. MATLAB simulation results show that compared with the LEACH algorithm, the improved algorithm balances the network load effectively, reduces the network energy consumption, and prolongs the network life cycle.

Keywords: marine incinerator; operational training system; scene simulation; web3D modeling

Abstract. In this paper, the design scheme, technical route and system structure of the interactive marine incinerator operation training system based on Web3D are proposed based on the study of the marine engine room simulator project. The virtual reality technique, visual C# and IE real-time interaction technology are introduced to the marine incinerator operation training system and the development thoughts of the interactive marine incinerator operation training system based on Web3D are elaborated based on the 3D modeling optimization and real-time interaction technology. This study is a new type of marine engineering training mode, it can better meet the STCW convention in Manila amendments on incinerator equipment management requirements.

Introduction

Large marine simulation system plays a very important role in terms of training high quality crew, it has become the effective means and methods for the maritime education and training. The STCW convention stipulated that crews can obtain certificate of competency though by undergo a certain time of simulator training[1]. But it can not satisfy the needs of student with the increasing of maritime colleges and training institutions because of the high cost of large marine simulation system were limited, the training ground were fixed, the training time was very limited. In recent years, with the rapid development of network technology and the performance improvement of personal computers, the maritime universities have established the campus network, most of the students also have a personal computer. These basic conditions makes the distributed simulation system based on Web is feasible.

At present, the simulation based on web3D attracts more attention, the simulation system based on Web3D were established in many fields, but it still very few in the field of navigation[2]. This project will combine the web3D technology closely with the marine incinerator plant simulation system. A new training pattern that the interactive marine incinerator operation training system based on Web3D is proposed, it makes that more students can perform certain online training course anytime and anywhere through the browser. This project has the properties of mobility and high interactivity, openness, easy maintenance and cost saving, etc., so that the students can easily connect to the specified Web site for training during any time any place, it can effectively make up the shortfall that the traditional remote education was limited to the predetermined learning program[3].

Overall Design

Developing the interactive marine incinerator operation training system based on Web3D is the purpose of this research by using virtual reality technology and combining with the teaching and training practice of marine engineering technology. In this paper the marine incinerator plant, web3D technology, virtual reality technology were studied, and the realization of the key research of training system based on web3D were developed, and the ActiveX control technology, server technology and multithreading technology were utilized for the operational training system. The idea is to realize the use of desktop machine and web browser to access the lifelike marine training through the network

environment. It can meet the international maritime organization and the national maritime bureau about the seafarers' training, certification and standards of the international convention on duty "competency assessment project" and "to demonstrate" continuous proficiency requirements. The concrete research content is as follows:

Mathematical Model Establishment and Optimization

The mathematical model of the marine incinerator plant was established and verified the related optimization according to the working principle structure characteristics of marine incinerator plant and the basis of thermodynamics and dynamics knowledge.

Implementation of Virtual Reality Simulation

The 3-D modeling for marine incinerator plant was realized by the 3dmax and SolidWorks[4], the virtual reality simulation of the Marine incinerator plant was accomplished by using VRML and then through the establishment of two-dimensional three-dimensional scene for communications between the interaction.

Marine Incinerator Plant Dynamic Process Simulation

On the basis of the system global model, the dynamic model simulation was realized by utilizing Matlab M-file function and by using the experimental data to validate the simulation value, correction algorithm, improve the system mathematical model, the correctness and efficiency of model were analyzed by SIMULINK software simulation.

Marine Incinerator Plant Fault Simulation Visualization Interface Development

The various fault phenomena or characteristics are analyzed though the established dynamic model of marine incinerator plant. The dynamic model was solved by VC# programming, and the correction coefficient was introduced, the value were tested for many times. Each subsystem and fault training system of marine incinerator plant were researched and developed, the results were called to monitor the system.

The Software Design and Implementation of Marine Incinerator Plant Simulation System based on Web3D

The interface design and development of marine incinerator plant simulation software were completed by combining with the established mathematical model of marine incinerator plant though Visual Studio.net 2010 that was act the development environment, with Visual computer programming language Visual c # as the programming tool, combining with VRML and Java technology solutions ,utilize GDI + technology to create control library. It adopt VRML for client interactive 3D graphics display of virtual Marine environment, and it adopt Java technology for network communication responsible, distributed simulation to more user interaction, marine simulation training and 3D scene data encoding decoding, and other functions[5].

Technical Implementation

According to the ship equipment data and practical investigation, combined with the marine incinerator plant training programs, the B/S frame was adopted to develop the simulator. The realistic 3D model of the equipment are established based on the virtual reality software, the function of virtual roaming and remote real-time interaction are developed by ActiveX technology and visual C# technology. Overall study plan is as follows:

(1).The realistic 3D model of the marine incinerator plant are established based on the actual size of the equipment by utilizing the Converse3D modeling tool and its development kit;

(2).For function simulation part, we utilize ActiveX of Converse3D by embedding C# language to develop the interactive marine incinerator operation training system based on Web3D combined with the practical of the training.

(3).For the multi-engineer cooperative training based on IE browser, we utilize the converse3D three-dimensional network platform and virtual community functions and embedding visual C# language to develop the remote visualization interactive control module[6].

(4).This paper makes some improvements aimed to the traditional B/S model: first programmed by the socket and run it in the client port to achieve real-time transition of the dynamic data, then realized the display of dynamic data in browses port by adopting ActiveX technique. Provide concrete resources for browses by using HTTP protocol to ascertain Web server through unified resources localizes. The mode of the improved project still through browses to visit embedded Web server, yet which combined the advantages of B/S and C/S.

System Structure

In order to make the engineers to simulate marine incinerator management status as far as possible, the interactive marine incinerator operational training system based on Web3D must have enough simulation environment, which can enable trainees to get and show the skills required by the training objectives. The operational training system should include simulation equipment: incinerator ontology, burner, exhaust fan, damper regulator, dirty oil circulation pump and other ancillary equipment, it can produce the random operation equipment sound simulation at the same time. It can not only more visually on a single engineer for regular working conditions and deal with the emergency case training through the operational training system[7], it can realize remote real-time operation and more engineers interaction. The software architecture is showed as Figs.1-3.

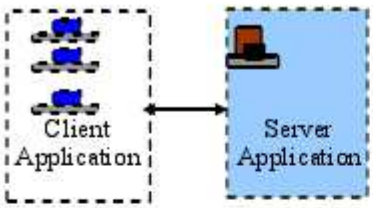

Fig 1 C/S

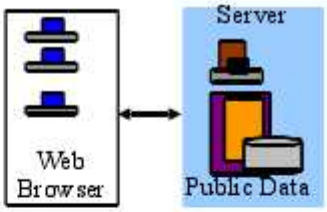

Fig 2 B/S

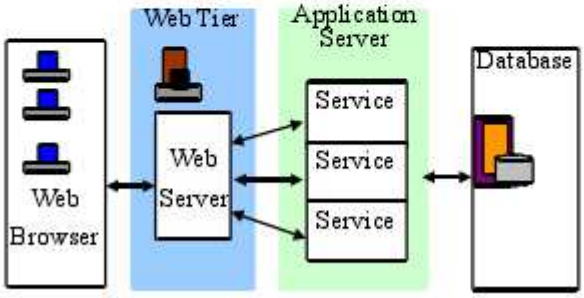

Fig 3 Multi-layer architecture based on web

Major Training Content Include:

(1) The operational training mode based on Web can be achieved;
(2) The 3D visual of marine incinerator plant can be provided;
(3) The operation control panel of marine incinerator plant can be provided in the client;
(4) The accurate mathematical model of marine incinerator plant can be provided in the client;
(5) The corresponding various operations of software control panel can be provided in the client;
(6) The fault setting and find the training function can be realized;
(7) The different training patterns can be chosen according to the requirement.

Conclusions

At present, with the rapid development of 3D virtual reality technology and the network technology, its application is becoming more and more widely in the field of education and training. It will have broad prospects to develop the online edition of the two-dimensional control system

combined with 3D simulation model of the comprehensive training of software though combining the advanced technology and marine simulator. This technology will be the focus direction of the marine engine room simulator in the future. It is believed that with the progress of science and technology, the development of shipping industry and the rapid development of virtual reality technology, the project studied operations training system will have a bigger development space, it will be more and more widely used because of its beyond the traditional simulation, and the advantages of the marine simulation training system based on Web has wide prospect of market demand and development, its role in the crew training will be more and more widely.

Keywords: Wireless sensor networks, Cluster based routing protocol, Review

Abstract. At present, cluster based routing protocols have been the main solution of routing scalability problem in wireless sensor networks. Based on the deep research on cluster based routing protocols, cluster based routing protocols were divided into two parts. The main routing protocols of each part were reviewed and analyzed. This work will contribute to the further study of cluster based routing protocols.

Introduction

In recent years, Internet of things has become a hot research topic in the academic and business circles. The wireless sensor network is the development core of Internet of Things in the current stage[1]. The research of wireless sensor networks has very high value. At present, applications of large-scale wireless sensor networks become more and more, such as coal mine environment detection, ecological monitoring of the Three Rivers Origin, etc[2-4]. Therefore, it becomes more and more urgent to research the scalability problem of wireless sensor networks. At present, cluster based routing protocols have become the main solution of routing scalability problem. Based on the deep research on cluster based routing protocols, cluster based routing protocols are divided into two parts. The main routing protocols of each part are reviewed and analyzed. This work will contribute to the further study of cluster based routing protocols.

Cluster based Routing Protocols and the Classification

The cluster based routing protocols in wireless sensor networks are routing protocols based on cluster structures. The protocols select cluster heads through some strategy. A cluster head and some cluster members constitute a cluster structure. The cluster members are responsible for collecting monitoring data and transmitting them to the cluster head. The cluster head is responsible for fusing the received monitoring data and forwarding them to the sink node. Compared with the flat routing protocols [5-9], cluster based routing protocols perform more prominent in network topology management, energy minimization and data fusion. At present, cluster based routing protocols have become the main solution of routing scalability problem. Cluster based routing protocols are divided into two-layer cluster based routing protocols and multi-layer cluster based routing protocols. We will review and analyze the above two kinds of protocols separately in this paper.

Review and Analysis of Two-layer Cluster based Routing Protocols

Two-layer cluster based routing protocols are routing protocols based on two-layer cluster structures. A two-layer cluster structure is shown in Fig.1.

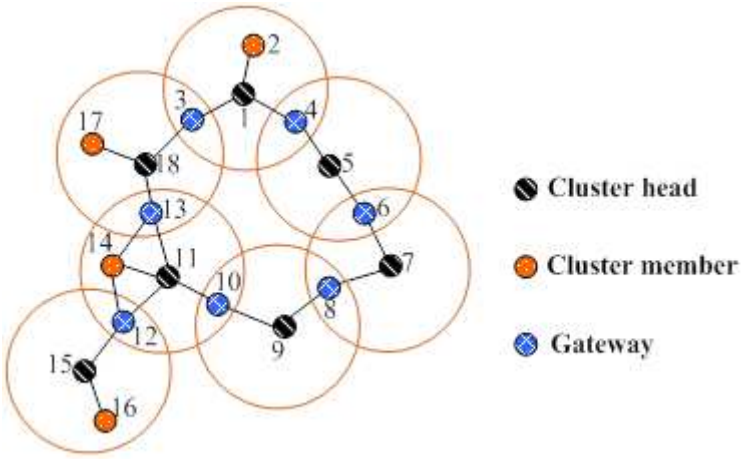

Fig.1 A two-layer cluster structure

At present, two-layer cluster based routing protocols have matured. For example, the LEACH protocol[10] is the first two-layer cluster based routing protocol in wireless sensor networks. It focus on solving the load balancing and energy control. But there are some problems in LEACH, such as "single hop communication mechanism between the cluster head and the sink node increases the energy of the cluster head" and "cluster head election strategy imbalances the energy of the cluster head". The most of the two-layer cluster based routing protocols after LEACH protocol are evolved based on LEACH protocol. They improve LEACH protocol from different angles. For example, the sink node elects the cluster heads consentrately by combining the energy and locations of all the nodes in LEACH-C protocol[11], which can solve the problem of unbalanced energy consumption of cluster heads. In HEED protocol[12], two decisive parameters are introduced during cluster constructing, such as node residual energy and intra-cluster communication cost, which can solve the problem of unbalanced energy consumption of cluster heads. The clustering method adopted by TEEN protocol[13] is the same with that adopted by LEACH protocol. And TEEN protocol adds two thresholds to reduce data amount, but it is not suitable for the application of periodic reporting data. Aiming at the problem that expensive cost is produced during the cluster constructing in LEACH protocol, PEGASIS protocol[14] is proposed. In PEGASIS protocol, only one cluster (chain) is formed in the network, and then the cluster head and the sink node communicate with each other. Aiming at the problem of "single hop" mechanism in LEACH protocol, RPBC protocol [15] is proposed in which "multiple hop" mechanism is adopted. Each cluster head establishes their own route to the sink node when the sink node broadcasts interest messages. The multi-hop communication from each cluster head to the sink node is achieved by the single-hop communications between cluster heads. Aiming at the same problem, LEACH_CHMST protocol [16] is proposed in which the minimum spanning tree of cluster heads is taken as the inter-cluster routing tree. And it can achieve the multi-hop communication between the cluster head and the sink node. HRPBC protocol [17] is proposed in which the cluster head finds the route to the sink node by broadcasting. And the cluster head arrives at the sink node with multiple hops, in which the communications between cluster heads are conducted by their common gateways.

The two-layer cluster based routing protocol is more suitable for large-scale wireless sensor networks than the flat routing protocol. But its backbone network still has the scalability problem. The routing protocol who can really solve the routing scalability problem of large-scale wireless sensor networks is the multi-layer cluster based routing protocol.

Review and Analysis of Multi-layer Cluster based Routing Protocols

Multi-layer cluster based routing protocols are routing protocols based on multi-layer cluster structures. A multi-layer cluster structure is shown in Fig.2.

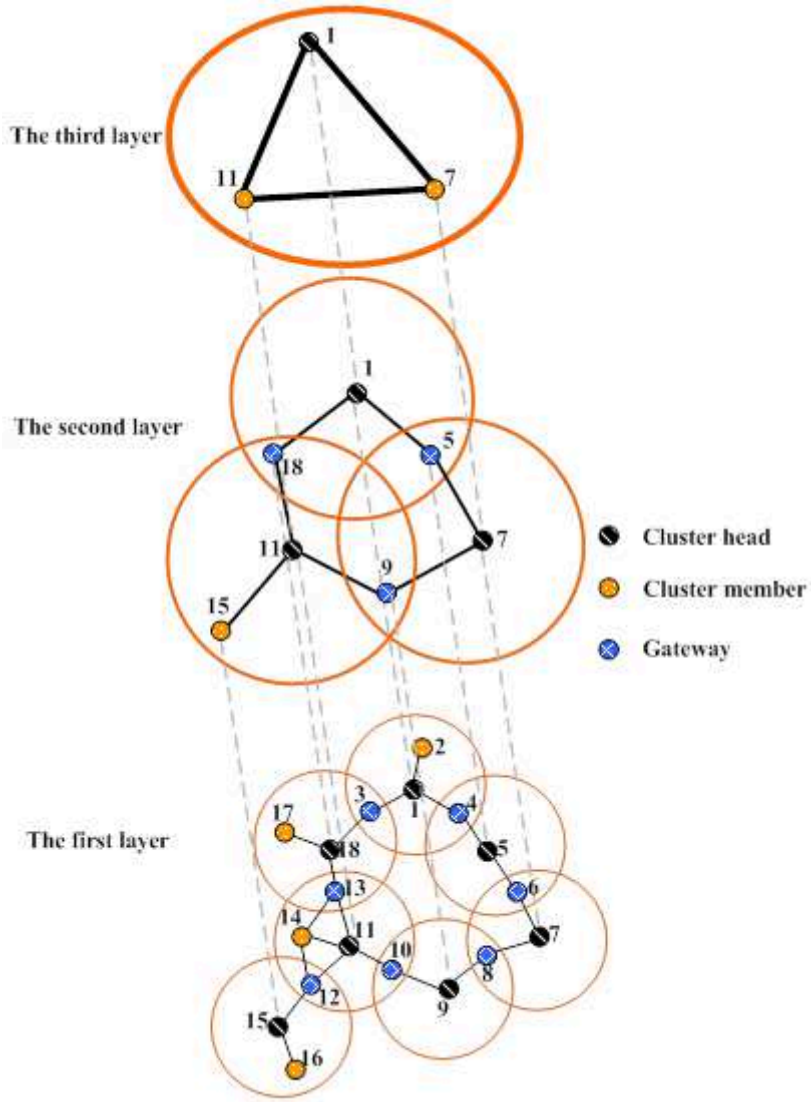

Fig.2 A multi-layer cluster structure

At present, the research results of multi-layer cluster based routing protocols are very seldom. It has not formed a perfect theory system. For example, CAMHP protocol[18] set up a context-aware cluster based routing protocol which is based on a three-layer cluster structure. But the network scalability is still limited. DETA protocol[19] is three-layer cluster based routing protocol. The constructing process of the three-layer cluster structure is that the network is divided into several square areas, which are equal size, adjacent and non-overlapping, according to the geographic location firstly; the bottom-layer cluster heads and upper-layer cluster heads are selected secondly. But the network scalability is still limited. The three-layer cluster structure constructed in literature [20] also exists the scalability problem. The constructing methods of the multi-layer cluster structure are presented in literature [21-23]. But the appropriate layers have no way to determine. The routing algorithms proposed in literature [24,25] present the methods of constructing the multi-layer cluster structure to the top layer. And they adopt multi-hop forwarding mechanism between the top-layer cluster head and the sink node. The design is complete. But the strategy "direct communication between cluster heads" makes the scalability of these algorithms limited. Therefore, the researches on multi-layer cluster based routing protocols for large-scale wireless sensor networks at home and abroad have many problems. It is necessary to carry out innovative theory researches.

Conclusion

In this paper, cluster based routing protocols of wireless sensor networks are deeply researched. The cluster based routing protocols are divided into two parts. The main routing protocols of each part are reviewed and analyzed. Cluster based routing protocols are divided into two-layer cluster based routing protocols and multi-layer cluster based routing protocols. The two-layer cluster based routing protocols have matured, but protocols still have the scalability problem. The multi-layer cluster based routing protocols take better scalability. But the relative researches have many problems. It is necessary to carry out innovative theory researches. We wish that the review and analysis in this paper will contribute to the further study of cluster based routing protocols.

Keywords: Host Scanning, Port Scanning, ICMP, TCP, UDP

Abstract. Host scanning and port scanning are the basis for attacking information system. The technologies commonly used in these scans can be classified as ICMP scanning, TCP scanning and UDP scanning. We analyze these technologies and make comparisons among them. Totally, ICMP are mainly used to discover the host, while the TCP and UDP are mainly for port scanning, except for ACK. At the same time, using certain special TCP datagram such as SYN packets and ACK packets, and UDP datagram, we can make a host scanning in a secret manner.

Introduction

Network scanning mainly includes host scanning, port scanning, service detection, operating system identification, and vulnerability scanning. Host scanning refers to host discovery and port scanning finds out the port is open or close. They are the basis for other scans and exploration in the following attack stages. The technologies commonly used in host and port scanning can be divided into three categories, which are ICMP scanning, TCP scanning and UDP scanning. We will analyze these three types of technologies and make comparisons among them. This paper is organized as following: In section 2, we introduce the ICMP scanning technologies; in section 3, scanning technologies based on TCP protocol are analyzed; in section 4, UDP scanning technologies are related; in section 5, we make comparisons among these scanning methods; we conclude this paper in section 6.

ICMP Scanning

Internet Control Message Protocol (ICMP) messages, delivered in IP packets, are used for out-of-band messages related to network operation or mis-operation. It is a key protocol to exchange control and error messages over the Internet [1].

2.1 ECHO Scanning

ECHO scanning is also called as ping. ECHO scanning works by sending specific types of network traffic, called ICMP Echo Request packets(ICMP type 8), to a specific interface on a computer or network device. If the device (and the attached network card) that received the ping packet is turned on and not restricted from responding, the receiving machine will respond back to the originating machine with an Echo Reply packet(ICMP type 0) . From this reply, we can say that the host is alive.

2.2 ICMP Sweep

An ICMP sweep is a series of pings that are automatically sent to a range of IP addresses, rather than manually entering the individual target's address. This type of scanning is suitable to scan a middle size of computer network.

2.3 Broadcast ICMP

Broadcast ICMP sets the aim of the ICMP Echo Request packets as a broadcast address or a network address, so the on-line host in this address will reply to the request packets and tell us that they are alive. But this method is only suitable to UNIX/Linux system, because the windows system will not replay to the broadcast ICMP Echo Requests. So we can identify the operating system according to this characteristic.

2.4 NON-ECHO Scanning

Except for the ECHO scanning, the ICMP Timestamp Request (ICMP type l3) and ICMP Address Mask Request (ICMP type l7) are also can be used to discover host. If the host is alive, it will reply with the ICMP Timestamp Reply (ICMP type l4) and ICMP Address Mask Reply (ICMP type l8).These methods can be used to discover host when the firewall blocks the ICMP ECHO packets.

2.5 Parameter Problem on a Datagram

If we send an IP datagram with wrong header length filed to a destination, the on-line host will reply with "Parameter Problem on a Datagram" ICMP packets (ICMP type l2). If no reply back, we can label the host as down or a firewall is in front of it.

2.6 Fragment Reassembly Timeout

If the IP datagram is fragmented, the destination host will start a timer when it gets the first fragment. In the following, if not all the fragments are received in the restricted time, the receiver will discard all the fragments and send back a "Fragment reassembly timeout" ICMP packet (Type 11, code 1) to the sender. According to this, we can discover a host by sending an incomplete IP fragments and receiving the "Fragment reassembly timeout" ICMP packet. If no reply back, we can label the host as down or a firewall is in front of it.

2.7 Protocol Unreachable

Sending an IP datagram with the wrong protocol to the destination, then the destination host will return the "Protocol Unreachable" packet which is one of the "Destination Unreachable"ICMP message. But if there is a firewall or a filter device in front of the target host, this reply will be flitted and no response will return to the source. So when sending an IP datagram with a large protocol number at least not used nowadays, the destination will return "protocol Unreachable" to the source, if so, we can get that the host is alive. Otherwise, if no "Destination Unreachable" ICMP data returned, we can infer there is a firewall in front of the host or the host is down. At the same time, we can deduce what protocols are in use according to the returned ICMP error messages. If "Destination Unreachable" is returned, the host is not using this protocol. On the contrary, if nothing back, the host may use this protocol, or the reply may be filtered by firewall, etc.

2.8 Port Unreachable

When sending a packets to unused port of the destination host, the host will reply with the "Port Unreachable"（ Type = 3, Code = 3） which is also one of the "Destination Unreachable" ICMP message. So when sending an IP datagram with a large port number little chance used, the destination will return "port Unreachable" to the source, if so, we can get that the host is alive. Otherwise, if no "Destination Unreachable" ICMP data returned, we can infer there is a firewall in front of the host or the host is down.

TCP Scanning

TCP provides reliable, ordered and error-checked delivery of a stream of octets between programs running on computers connected to a local area network, intranet or the public Internet. Resident at the transport layer, it casts congestion may happen in high-bandwidth and low-latency networks when multiple synchronized servers send data to the same receiver in parallel [2].

3.1 TCP Connect Scanning

The scan host establishes a connection to a port on the destination host based on Three-Way Handshake principle which is shown in Fig.1. In detail, this connection is started by calling the function "connect ()". If the port is open, the connection will be established. Otherwise, it will return -1 for the calling, indicating the port is closed [3].

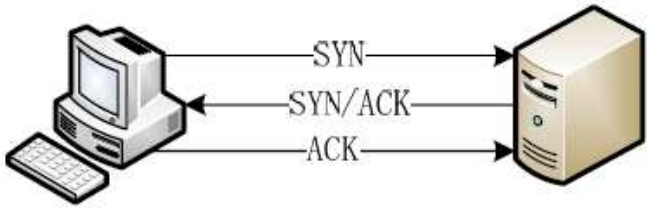

Fig.1 Three-Way Handshake

3.2 SYN Scanning

In a SYN scan, the scanning host sends a SYN packet, only with the SYN tag labeled, to the destination. If the target responds with a SYN/ACK, we can get the port is in use and then the scanning host discontinues the process by sending a "RST" to the target. Otherwise, when sending the SYN to the target, if it responds with a RST, we can get the port is close. At the same time, if we get nothing after sending the SYN to the target, we can mark the host as down. Because this process does not establish a connection, so it may not be record by some application and logs and it provides a level of obscurity or stealth [4].

3.3 ACK Scanning

The same with SYN scan, in an ACK scanning, the scanning host sends an ACK packet, only with the ACK tag labeled, to the destination. Whether the port is open or close, as long as the target host is alive, the destination will responds with a RST, for it has not sent a SYN to that scanning host and feels obscure to this ACK. If nothing back, we can label the target host as down. According to whether the ACK packet can pass the firewall, we can identify the packet filtering firewall with state inspection firewall [5,6]. This type of scan also has obscurity.

3.4 FIN Scanning

Sending a FIN packet to a certain port on the destination, if nothing replied back, we can get the host is alive and port is open. If the target replied with RST, we can get that the host is alive but the port is close. This type of scan also has obscurity. The theory basis of this scan method is the TCP RFC, which says that if a closed port receives a packet that does not have a SYN, ACK, or RST flag set, the port should respond with an RST packet of its own. Furthermore, the RFC states that if the port is open and it receives a packet without a SYN, ACK, or RST flag set the packet should be ignored.

3.5 NULL Scanning

In a NULL scans, which is also an obscures scan, the scan host sends a packet devoid of any flags to a certain port on the destination. Given TCP RFC, a NULL packet should be replied with RST when the port on the destination is close and should be replied with nothing when the port is open.

3.6 Xmas Scanning

In an Xmas scans, the scan host sends a packet with the FIN, PSH, and URG packet flags are all set to "on"to a certain port on the destination. Given TCP RFC, an Xmas packet should be replied with RST when the port on the destination is close and should be replied with nothing when the port is open.

UDP Scanning

The User Datagram Protocol (UDP) is one of the core members of the Internet protocol suite.With UDP, computer applications can send messages, in this case referred to as datagrams, to other hosts on an Internet Protocol (IP) network without prior communications to set up special transmission channels or data paths. We use UDP other than TCP for video and audio streaming service or online gaming where data travel speed or bandwidth has more priority compared to reliability [7].

For UDP is a connectionless protocol, when sending packets to a UDP port, it will return nothing to the source if the port is open, while if the port is closed, some systems will reply with ICMP Port Unreachable. It is the same with section 2.8. But since UDP is not a reliable connection-oriented protocol, this scanning method is easy to get wrong conclusion with packets dropping.

Comparisons of the Methods

Here, we make comparisons among all these 15 scanning methods related above to show for what tasks these methods can be used. The tasks refer to host scanning and port scanning. The results are shown in Table 1. As the principle of "Port Unreachable" is the same with that of "UDP Scanning", we merge them into "UDP/Port". In this table, the name of every scanning is demonstrated by the main part of its original name to save space. If the scanning method is suitable for such task, we label

a " √ " in the corresponding blank. From this table, we can see that (1) Totally, ICMP are mainly used to discover the host, while the TCP and UDP are mainly for port scanning, except ACK. (2) Though belong to the TCP datagram, ACK packets only can be used for host scanning, for it cannot tell the difference between the open and close ports. (3) SYN scanning and UDP scanning can be used for both port and host scanning. (4) SYN, ACK, FIN, NULL, Xmas and UDP scanning can complete their tasks in a secret way, which may not be logged by applications or systems.

Table 1 Comparisons among Scanning Methods

	Ping	Sweep	Broadcast	Non-echo	Parameter	Fragment	Protocol
Host	√	√	√	√	√	√	√
Port							
	TCP	SYN	ACK	FIN	Null	Xmas	UDP/Port
Host		√	√				√
Port	√	√		√	√	√	√

Conclusion

Network protocols such as ICMP, TCP and UDP can be used for host scanning and port scanning. Some of the scanning methods are elaborately designed to pass the examinations of firewalls. So, comprehensively using these methods can give us a more accurate and complete knowledge of the hosts and their ports. Totally, ICMP are mainly used to discover the host, while the TCP and UDP are mainly for port scanning, except for ACK. At the same time, using certain special TCP datagram such as SYN and ACK packets, and UDP datagram, we can make a host scanning in a secret manner.

Keywords: Multicarrier, CDMA, Internet of Things

Abstract. Massive amounts of data frequently need to be communicated in the internet of things where the channel is wireless. CDMA is a good technology to combat fading. In order to improve the system capacity or the spectrum efficiency, more than one carrier can be employed. Both the transmitter structure and that of the receiver are given in this paper. The interference item, as well as the received signal, is carefully analyzed. A summary, after some simulation results is given in the end.

Introduction

Recently, the internet of things (IOT) is one of the research hotspots [1-2]. Being a successor of internet, it has broader use. After massive data are obtained from lots of sensor nodes, communication with high quality becomes indispensable. More often than not, wireless or mobile application accounts for a large proportion. Code division multiple access (CDMA) system is famous for combating multipath fading in wireless communication [3]. Large-area-synchronized (LAS) codes are very suitable to act as the multiple access codes (MACs) due to their good auto-correlation property and cross-correlation property [4-5]. In our research, the multicarrier technology is applied to CDMA system using LS codes which is the specific LAS codes in one cell situation.

System Model

At first, we talk about the correlation function between LS code c_m and c_n, named $R_{mn}(p)$. If the absolute value of p is not greater than the width of the zero correlation zone (ZCZ), $R_{mn}(p)$ is zero except $R_{mm}(0)=1$ for normalization. Suppose that the unit pulse response function of the wireless fading channel is $h_{ku}(t)=\sum_{l=1}^{L}\alpha_{ku}^{l}\delta(t-\tau^{l})$, where α_{ku}^{l} is the fading coefficient, τ^{l} is the time delay and L is the number of multipath.

The transmitter of user k is shown in Fig. 1. The frequency of the carrier u is $f_u, u=1,2,\cdots,U$. The data of the user k is $d_k[i], i=0,1,2,\cdots$. The multiple access code of user k is c_k. So that the signal of user k corresponding to carrier u is $d_{ku}(t)=\sum_{i=-\infty}^{+\infty}d_{ku}[i]p_{T_s}(t-iT_s)$, where $d_{ku}[i]=d_k[i]\big|_{(i \bmod U)+1=u}$ and $p_{T_s}(t)$ is the forming pulse with duration time of one symbol. Therefore the transmitting signal of user k is $s_k(t)=\sum_{u=1}^{U}d_{ku}(t)c_k(t)e^{j2\pi f_u t}$, where $c_k(t)=\sum_{n=0}^{N_c}c_k[n]p_{T_c}(t-nN_c)$, $p_{T_c}(t)$ is the (rectangular) pulse with duration time of one chip and N_c is the length of MAC sequence.

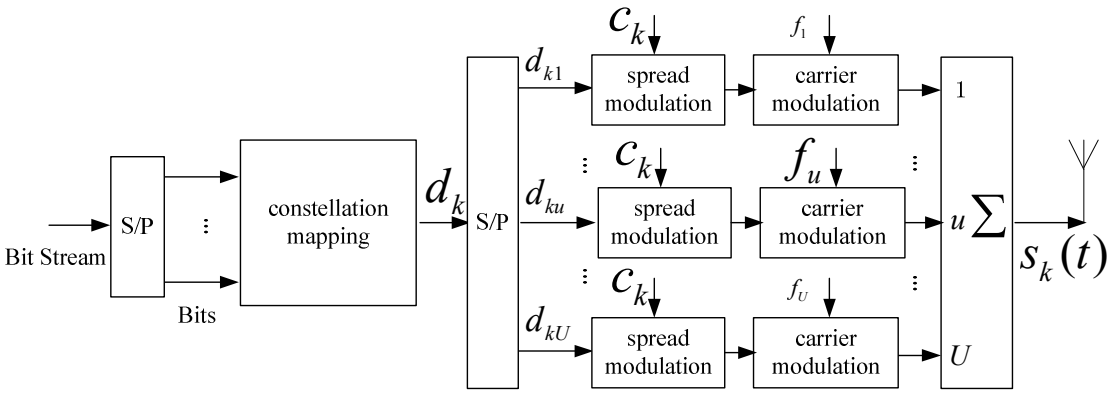

Figure 1. The transmitter model of user *k*

The receiver model of any given user *n* is showed in Fig. 2, where g_{nm}^{v} ($m=1,2,\cdots,U$; $v=1,2,\cdots,L$) are the coefficients of multipath combination.

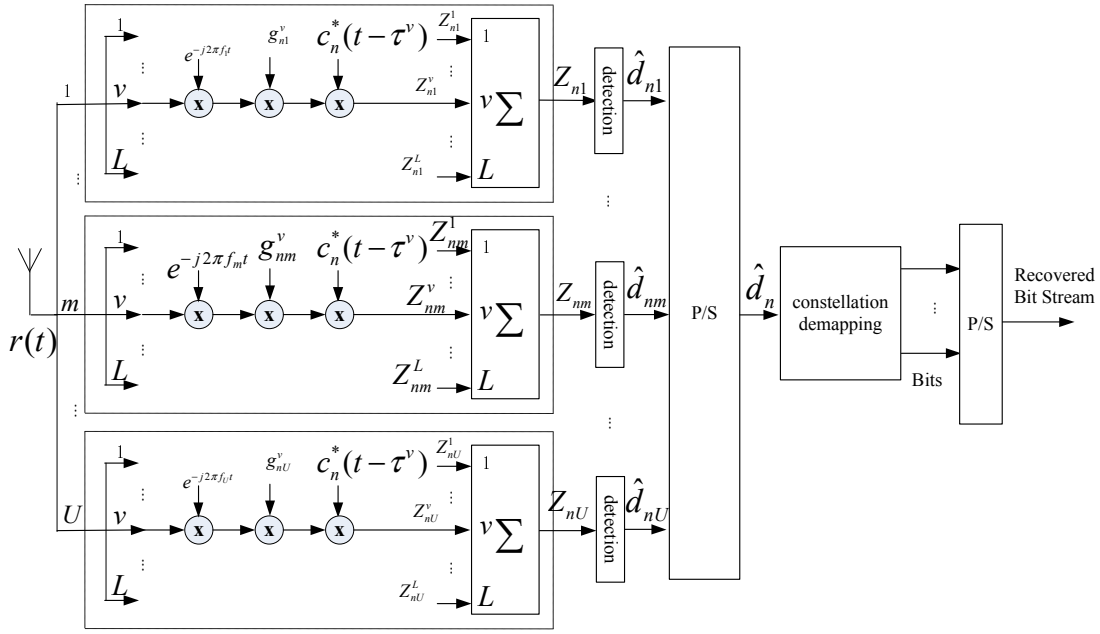

Figure 2. The receiver model of user *n*

The received signal $r(t)$ can be notated as follows, where $n(t)$ is the Gaussian noise

$$r(t)=\sum_{k=1}^{K}\sum_{u=1}^{U}\sum_{l=1}^{L}\alpha_{ku}^{l}d_{ku}(t-\tau^{l})c_{k}(t-\tau^{l})e^{j2\pi f_{u}(t-\tau^{l})}+n(t) \tag{1}$$

Thus, the *m*-th output of user *n* on decision time $T_s+(L-1)T_c$ is $Z_{nm}=\sum_{v=1}^{L}Z_{nm}^{v}$ $n=1,2,\cdots,K;m=1,2,\cdots,U$ where

$$Z_{nm}^{v}=\frac{1}{T_s}\int_{\tau^{v}}^{T_s+\tau^{v}}r(t)g_{nm}^{v}c_{n}^{*}(t-\tau^{v})e^{-j2\pi f_{m}(t-\tau^{v})}dt$$

$$=\sum_{k=1}^{K}\sum_{u=1}^{U}\sum_{l=1}^{L}\left\{\frac{1}{T_s}\int_{\tau^{v}}^{T_s+\tau^{v}}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}(t-\tau^{l})c_{k}(t-\tau^{l})c_{n}^{*}(t-\tau^{v})\ c_{n}^{*}(t-\tau^{v})e^{j2\pi[f_{u}(t-\tau^{l})-f_{m}(t-\tau^{v})]}\right]dt\right\}+\eta_{nm}^{v}$$

$$\eta_{nm}^{v}=\sum_{k=1}^{K}\sum_{u=1}^{U}\sum_{l=1}^{L}\frac{1}{T_s}\int_{\tau^{v}}^{T_s+\tau^{v}}n(t)g_{nm}^{v}c_{n}^{*}(t-\tau^{v})e^{-j2\pi f_{m}(t-\tau^{v})}dt \tag{2}$$

Therefore $Z_{nm}=\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{u=1}^{U}\sum_{l=1}^{L}\left\{\frac{1}{T_s}\int_{\tau^v}^{T_s+\tau^v}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}(t-\tau^l)c_k(t-\tau^l)\ c_n^*(t-\tau^v)e^{j2\pi[f_u(t-\tau^l)-f_m(t-\tau^v)]}\right]dt\right\}+\sum_{l=1}^{L}\eta_{nm}^{v}$.

When the width of the zero correlation zone of LS code is great enough, we obtain

$$\begin{aligned}&\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{u=1}^{U}\sum_{l=1}^{L}\Psi(n,m,v,k,u,l)\\&=\sum_{v=1}^{L}\Psi(n,m,v,k,u,l)\big|_{k=n,u=m,l=v}+\sum_{v=1}^{L}\sum_{\substack{l=1\\l\neq v}}^{L}\Psi(n,m,v,k,u,l)\big|_{k=n,u=m}+\sum_{v=1}^{L}\sum_{\substack{k=1\\k\neq n}}^{K}\sum_{l=1}^{L}\Psi(n,m,v,k,u,l)\big|_{u=m}+\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{\substack{u=1\\u\neq m}}^{U}\sum_{l=1}^{L}\Psi(n,m,v,k,u,l)\\&=D_{nm}+\Upsilon_{nm}^{(1)}+\Upsilon_{nm}^{(2)}+\Upsilon_{nm}^{(3)}\end{aligned}\tag{3}$$

where $\Psi(n,m,v,k,u,l)=\frac{1}{T_s}\int_{\tau^v}^{T_s+\tau^v}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}(t-\tau^l)c_k(t-\tau^l)\ \ c_n^*(t-\tau^v)e^{j2\pi[f_u(t-\tau^l)-f_m(t-\tau^v)]}\right]dt$

The information signal transmitted exists in D_{nm}, spoiled by channel fading of course. The last three interference items in equation (4) are respectively as follows: $\Upsilon_{nm}^{(1)}$ is the interference between paths having different delay within one user of the same carrier, $\Upsilon_{nm}^{(2)}$ is the interference between different users that use the same carrier, $\Upsilon_{nm}^{(3)}$ is the others interference that is not included in the former two interference items.

Remembering that $R_{nn}(0)=1$, we obtain the first item

$$\begin{aligned}D_{nm}&=\sum_{v=1}^{L}\Psi(n,m,v,k,u,l)\big|_{k=n,u=m,l=v}=\sum_{v=1}^{L}\frac{1}{T_s}\int_0^{T_s}g_{nm}^{v}\alpha_{nm}^{v}d_{nm}(t)c_n(t)c_n^*(t)dt=\sum_{v=1}^{L}\frac{1}{T_s}\int_0^{T_s}g_{nm}^{v}\alpha_{nm}^{v}d_{nm}[0]c_n(t)c_n^*(t)dt\\&=\sum_{v=1}^{L}g_{nm}^{v}\alpha_{nm}^{v}d_{nm}[0]R_{nn}(0)=\sum_{v=1}^{L}g_{nm}^{v}\alpha_{nm}^{v}d_{nm}[0]\end{aligned}\tag{4}$$

The last item is worked out as

$$\begin{aligned}\Upsilon_{nm}^{(3)}&=\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{\substack{u=1\\u\neq m}}^{U}\sum_{l=1}^{L}\Psi(n,m,v,k,u,l)=\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{\substack{u=1\\u\neq m}}^{U}\sum_{l=1}^{L}\frac{1}{T_s}\int_{\tau^v}^{T_s+\tau^v}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}(t-\tau^l)c_k(t-\tau^l)\,c_n^*(t-\tau^v)e^{j2\pi[f_u(t-\tau^l)-f_m(t-\tau^v)]}\right]dt\\&=\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{\substack{u=1\\u\neq m}}^{U}\sum_{l=1}^{L}\frac{1}{T_s}\int_0^{T_s}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}(t+\tau^v-\tau^l)c_k(t+\tau^v-\tau^l)\,c_n^*(t)e^{j2\pi[f_u(t+\tau^v-\tau^l)-f_m t]}\right]dt\approx\sum_{v=1}^{L}\sum_{k=1}^{K}\sum_{\substack{u=1\\u\neq m}}^{U}\sum_{l=1}^{L}\frac{1}{T_s}\int_0^{T_s}\left[g_{nm}^{v}\alpha_{ku}^{l}d_{ku}[0]c_k(t+\tau^v-\tau^l)\,c_n^*(t)e^{j2\pi[f_u(t+\tau^v-\tau^l)-f_m t]}\right]dt\end{aligned}\tag{5}$$

In the same way, we can get

$$\begin{aligned}\Upsilon_{nm}^{(1)}&=\sum_{v=1}^{L}\sum_{\substack{l=1\\l\neq v}}^{L}\Psi(n,m,v,k,u,l)\big|_{k=n,u=m}\approx\sum_{v=1}^{L}\sum_{\substack{l=1\\l\neq v}}^{L}g_{nm}^{v}\alpha_{nm}^{l}d_{nm}[0]e^{j2\pi f_m(\tau^v-\tau^l)}R_{nn}^*(\tau^l-\tau^v)=0\\\Upsilon_{nm}^{(2)}&=\sum_{v=1}^{L}\sum_{\substack{k=1\\k\neq n}}^{K}\sum_{l=1}^{L}\Psi(n,m,v,k,u,l)\big|_{u=m}\approx\sum_{v=1}^{L}\sum_{\substack{k=1\\k\neq n}}^{K}\sum_{l=1}^{L}g_{nm}^{v}\alpha_{km}^{l}d_{km}[0]e^{j2\pi f_m(\tau^v-\tau^l)}R_{nk}^*(\tau^l-\tau^v)=0\end{aligned}\tag{6}$$

So we get $Z_{nm}\approx d_{nm}[0]\left(\sum_{v=1}^{L}g_{nm}^{v}\alpha_{nm}^{v}\right)+\Upsilon_{nm}^{(3)}+\sum_{l=1}^{L}\eta_{nm}^{v}$. The first two items $\Upsilon_{nm}^{(1)}$ and $\Upsilon_{nm}^{(2)}$ are little and many parts of $\Upsilon_{nm}^{(3)}$ can be counteracted, which leads to greatly decrease the interference. The recovered signal of user n corresponding to carrier m, i.e. $d_{nm}[0]$ in equation (4) can be easily achieved. Therefore, the system performance of such multicarrier CDMA system increases greatly.

Performance Simulation

The main simulation parameters used in the computer experiments are shown in table 1.

The bit-error-rate versus signal-to-noise ratio performance simulation results of this kind of multicarrier CDMA are shown in Fig. 3. From this figure, we can easily notice that, when the number of subcarrier is relatively small, the performance is almost equivalent to that of the single carrier system. In the same time, the system capacity almost enhances linearly to the number of carriers.

Table 1. The main simulation parameters

Parameters	Values
Spread factor	512
Channel model	ITU-VA
Velocity	70 km/h
Number of carrier	1,2,4,8,16
Channel estimation algorithm	Ideal channel estimation
Mapping constellation	64QAM
Equalization algorithm	MMSE equalization

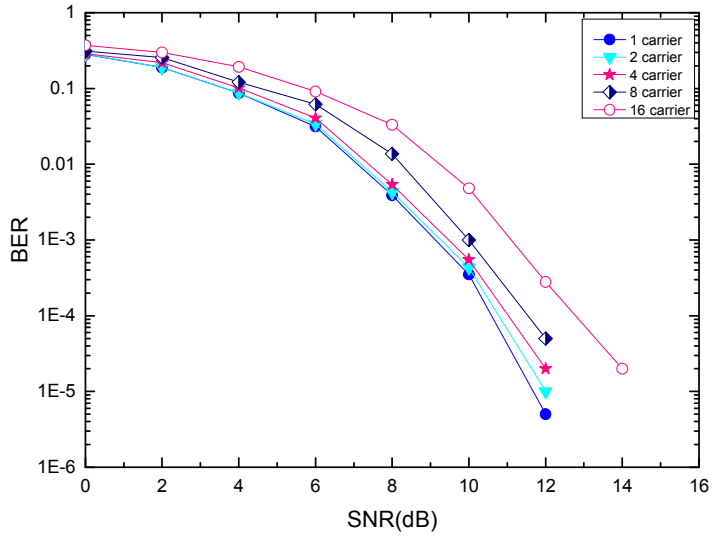

Figure 3. The bit-error-rate performance of the multicarrier CDMA system

Summary

On the one hand, thanks to the existence of zero correlation zones in the correlation functions of the LS codes, the system capacity of such kind multicarrier CDMA system can be greatly increased by employing multicarrier technology. On the other hand, the system bit-error-rate performance has little loss as compared with that of single carrier system. As the system performance of such kind of multicarrier CDMA system using LS codes is excellent, all the merits of such system make it suitable to future IOT wireless application.

Keywords: wireless sensor networks; ant colony algorithm; energy consumption; stable cluster

Abstract. Aiming at the shortcomings of slow convergence speed and instable optimal routing which will occur when ant colony algorithm is applied in wireless sensor networks, an improved algorithm is proposed in this paper, which can be used to optimize cluster heads number, cluster unequally and keep the majorizing clusters stable. In addition, the improved ant colony algorithm is used for routing in the majorizing cluster. Simulation experiments show that the stable cluster colony algorithm is useful in reducing the energy consumption and improving the speed of data package transmission.

Introduction

Wireless Sensor Network (WSN) is a new research area of computer science and technology. It consists of the convergence of sensor, micro-electro-mechanism system and network technologies. Wireless sensor network is supposed to have a variety of applications in the future [1].

A wireless sensor network (WSN) is consist of many spatially distributed autonomous sensors. It can monitor physical or environmental conditions, such as temperature, sound, pressure, etc. and cooperatively pass their data through the network to a main location. The development of wireless sensor network was motivated by military applications such as battlefield surveillance [2]. Today wireless sensor networks are used in many industrial and consumer applications, such as industrial process monitoring and control, machine health monitoring, and so on.

The WSN is built of nodes which are from a few to several hundreds or even thousands, where each node is connected to one (or sometimes several) sensors. Each such sensor network node has typically several parts: a radio transceiver with an internal antenna or connection to an external antenna, a microcontroller, an electronic circuit for interfacing with the sensors and an energy source, usually a battery or an embedded form of energy harvesting.

Because of the useful characteristics, including easy to be realized, supporting multi-path, ant colony algorithm was introduced into the routing selection of stable clusters in wireless sensor networks. Then an improved ant colony algorithm based on stable clusters was proposed in this paper. Simulation experiments show that the stable cluster colony algorithm is useful in reducing the energy consumption and improving the speed of data package transmission.

Ant Colony Algorithm

The ant colony algorithm (ACO) is a probabilistic technique for solving computational problems which can be reduced to finding optimal paths through graphs.

The first version of ant colony algorithm, which is initially proposed by Marco Dorigo in 1992 in his PhD thesis [3], was aiming to search for an optimal path in a graph, based on the behavior of ants seeking a path between their nest and a source of food. The original idea has since diversified to solve a wider class of numerical problems, and as a result, several problems have emerged, drawing on various aspects of the behavior of ants.

In the natural world, ants initially wander randomly, and upon finding food return to their nest while laying down pheromone trails. If other ants find such a path, they are likely not to keep

travelling at random, but to instead follow the trail, returning and reinforcing it if they eventually find food. When the ant k moves to the next node j from node i, the node j can be decided with the probability $P_{ij}^{k}(t)$ which can be calculated by formula (1):

$$P_{ij}^{k}(t)=\begin{cases}\dfrac{\tau_{ij}^{\alpha}(t)\eta_{ij}^{\beta}(t)}{\sum_{s\in A_k}\tau_{is}^{\alpha}(t)\eta_{is}^{\beta}(t)} & j\in A_k\\ 0 & otherwise\end{cases} \tag{1}$$

Where $\tau_{ij}(t)$ denotes the pheromone density, A_k is the set of optional nodes adjacent to node i. α is the heuristic factor of pheromone. β is the heuristic factor of expectation. $\eta_{ij}(t)$ is the distance function which denotes the heuristic information of path. $\eta_{ij}(t)$ can be described as formula (2):

$$\eta_{ij}(t)=\frac{1}{d_{ij}} \tag{2}$$

Where d_{ij} denotes the distance from node i to node j.

Over time, however, the pheromone trail starts to evaporate, thus reducing its attractive strength. The more time it takes for an ant to travel down the path and back again, the more time the pheromones have to evaporate. A short path, by comparison, gets marched over more frequently, and thus the pheromone density becomes higher on shorter paths than longer ones. Pheromone evaporation also has the advantage of avoiding the convergence to a locally optimal solution. If there were no evaporation at all, the paths chosen by the first ants would tend to be excessively attractive to the following ones. In that case, the exploration of the solution space would be constrained.

Local pheromone updating strategy is regarded as follows:

$$\tau_{ij}(t+n)=(1-\rho)\cdot\tau_{ij}(t)+\Delta\tau_{it}(t) \tag{3}$$

Where ρ is the evaporation rate of pheromone. $\Delta\tau_{it}(t)$ denotes the increment of pheromone on path (i , j) during once iteration. $\Delta\tau_{it}(t)$ can be gain by formula (4) as follows:

$$\Delta\tau_{it}(t)=\begin{cases}Q/L_k & (i,j)\\ 0 & otherwise\end{cases} \tag{4}$$

Where Q is the pheromone density and L_k denotes the total length of the route ant k passed by.

Improved Ant Colony Algorithm Based on Stable Clusters (ACA-SC)

There are several limitations when ant colony algorithm is applied in wireless sensor networks. The priority of the specific node is not focused well enough when the amount of nodes is too big. So that the optimal routing selected by ant colony algorithm is instable, and what's worse, the convergence speed is slow and energy consumption is high.

The improved ant colony algorithm (ACA-SC) proposed in this paper selects the cluster-heads based on energy. The cluster-heads exchange the information of its distance and remaining energy with its neighborhood [4]. Then the distance and remaining energy of the neighborhood are integrated into the computation of pheromone concentration. Finally the data packet will choose its next hop with probability, which is computed on the basis of pheromone value [5].

Cluster-heads Selection. The improved cluster-heads selection strategy consists of two stages including primary selection of cluster-heads and cluster-heads adjustment.

Primary Selection of Cluster-heads. First of all, set an energy threshold E_{th}. During the procedure of primary selection of cluster-heads, one node will be chosen as the candidate cluster-heads only if its energy is greater than the threshold E_{th}. The energy threshold E_{th} can be calculated as follows:

$$E_{th} = E_0 \times (1 - \frac{R}{N}) \tag{5}$$

Where R is the number of rounds being executed, E_0 is the initial energy of every node, E_{th} denotes the limiting value of energy on the cluster-heads at the Rth round.

Introducing the energy threshold into cluster-heads selection strategy can effectively prevent the nodes with low energy from being chosen as cluster-heads and void the problems that cluster-heads die and stable cluster disappear.

Cluster-heads Adjustment. In the procedure of cluster-heads adjustment, one normal node sends candidate cluster-heads broadcasting message to other normal nodes within communication radius after it has been chosen as a candidate cluster-head. The message includes the label of the new candidate cluster-head and the remaining energy value of it.

Each candidate cluster-head establishes the list of neighbor candidate cluster-heads which includes the labels of neighbor candidate cluster-heads, remaining energy values, the times being chosen as cluster-head and the adjacent relationship among other candidate cluster-heads.

If one node is near enough with another neighbor node so that the distance from the node to its neighbor is less than the distance threshold, these two nodes are called close nodes. The weight of close nodes can be calculated by formula (6) as follows:

$$W_{cn} = a \times \frac{E_r}{E_{node}} + b \times C_{cn} \tag{6}$$

Where E_r denotes the remaining energy of neighbor node, E_{node} denotes the initial energy of node. Both a and b are weight factors. The node with the maximal energy will be chosen as the final cluster-head at this round.

Improved Method for Choosing Normal Nodes into Cluster-heads. The criterion of cluster selection only focuses on the distance between normal nodes and cluster-heads according to LEACH protocol. If one normal node with the nearest distance from the cluster-heads, it can be joined into the cluster.

Suppose every distance between one cluster-head and sink node is greater than d_0. The much nearer the distance between cluster-heads and sink node is, the less energy consumed when transporting data [6]. Therefore the distance from one normal node to sink node should be considered when choosing normal node as a cluster-head.

The formula of improved method for choosing normal nodes into cluster-heads is:

$$COST\ (ch) = \begin{cases} f\ (d_{ch}) & d_{ch} > d_0 \\ g\ (d_{ch}) & d_{ch} \le d_0 \end{cases} \tag{7}$$

$$f\ (d_{ch}) = \frac{d_J - d_{\min J}}{d_{\max J} - d_{\min J}} \tag{8}$$

$$g\ (d_{ch,bs}) = \frac{d_S - d_{\min S}}{d_{\max S} - d_{\min S}} \tag{9}$$

Where d_j denotes the distance from the normal node to the temporary cluster-head, d_S denotes the distance from cluster-head to base station, $d_{\max J}$ denotes the expectation maximization distance from the normal node to temporary cluster-head, $d_{\min J}$ denotes the expectation minimization distance from the normal node to temporary cluster-head. $d_{\max S}$, $d_{\min S}$ separately denote the maximal and minimal distance from the cluster-head to base station.

ACA-SC and Its Application on Stable Cluster. Through the steps mentioned above, the wireless sensor network is divided into several small clusters. Then we apply ACA-SC to select optimal routing in small clusters and the convergence speed is quicker than before.

The improved transition probability is described as follows:

$$P_{ij}^{k}(t)=\begin{cases}\dfrac{\tau_{ij}^{\alpha}(t)\omega_{ij}^{\beta}(t)}{\sum_{s\in A_k}\tau_{is}^{\alpha}(t)\omega_{is}^{\beta}(t)} & j\in A_k\\ 0 & otherwise\end{cases} \tag{10}$$

Where $\omega_{ij}(t)$ denotes the energy grade which is calculated by formula (11):

$$\omega_{ij}(t)=\frac{(I-e_j)^{-1}}{\sum_{n\in R_s}(I-e_n)^{-1}} \tag{11}$$

Where I denotes the initial energy of nodes, e_j denotes the current energy of the receiving node.

Furthermore, ACA-SC uses local memory of each node to save the messages passing by it. If the new message received is already saved in the local memory, the repeated message will be omitted.

Experimental Results

The simulation experiments are carried out in the MATLAB by using ACA-SC and basic ant colony algorithm (ACO) separately. The simulation data include: base station position is at (50,175), sensor region is 100m×100m, the number of nodes is 300, initial energy of nodes is 0.5J, length of message is 4000bits. The experimental results are shown in Fig.1 and Fig.2.

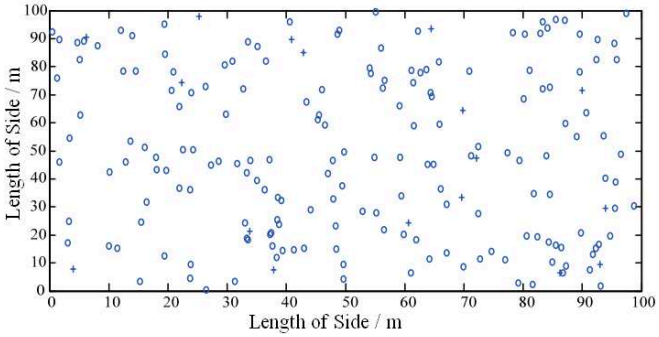

Fig.1 Topological Structure of ACA-SC

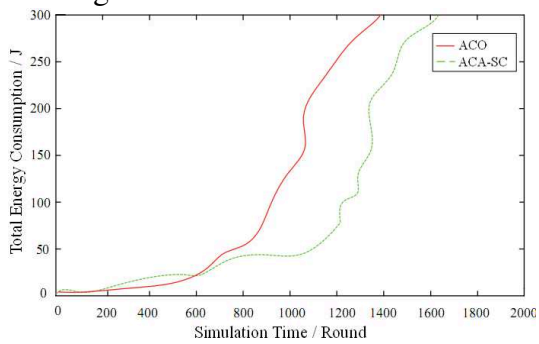

Fig.2 Comparison of Energy Consumption

Conclusion

In this paper an improved ant colony algorithm based on stable cluster was proposed. The improved algorithm takes advantages of optimal number of cluster-heads and optimal method for choosing normal nodes into cluster-heads to gain the stable clusters, and then applies ACA-SC in clusters to find the optimal routing. Furthermore the energy consumption of wireless sensor network has been decreased.

Research the architecture of a new Leisure Agriculture Intelligent System Base on the Internet of Things

Lin Yuan-guai

College of Electronics Information and Engineering, Qiongzhou University Technology, SanYa, Hainan, 572022, China

email: lyg_top@163.com

Keywords: Leisure agriculture; intelligent system; internet of thing; intelligent Cultivation Device; J2EE

Abstract. According to Hainan smart tourism problem characteristic, a new leisure agriculture intelligent system was proposed combining agricultural technology and the Internet of Things technology. The paper illustrates the overall structure of the system, then design the software platform frame of the system which on Struts, Hibernate, Spring Framework for J2EE technology. The system may provide an effective solution for leisure agricultural intelligent; the intelligent data center analyzes and processes the data, combine with the expert decision-making system, providing support for the user to better understand, then real-time tracking, make cultivation strategies or control online, the user can browse the information via the Internet .

Introduction

In recent year, leisure trips have been bloom. Leisure agriculture is a new kind of industry which combined agriculture with tourism [1]. The development of agriculture fallow and sightseeing tourism plays an important role in promoting the new rural construction, is also response to the specific implementation of the national 12th five-year plan [2]. At present, the focus of loyal tourism is being transferred to a leisurely vacationing tour with the target of building the Hainan Island into a tropical beach holiday resort in an eco-friendly environment. The Hainan international tourism island construction brings good opportunity for the development of leisure agriculture. Sanya is the most popular tourist area in Hainan, the development of leisure agriculture has the advantageous conditions, where has rich tropical agricultural landscape and varieties of agricultural resources. At present smart tourism relatively falls behind actually in Hainan province.

With the development of Internet of Things (IOT), it has become increasingly important for agricultural modernization and tourism intelligent. The development of leisure agriculture in Sanya needs the network platform based on IOT. The paper in view of the actual situation of leisure agriculture development based on the Internet of Things technology, combined with the agricultural technology, analyzes and studies the IOT application in leisure agriculture, then designs the architecture of a new leisure agricultural intelligent system. Anybody can browse the reality scenic of leisure agriculture. The system can remote manage the reality farm crops through the internet. The application of the internet of things in leisure agriculture not only meet the "low carbon" concept, but also can greatly improve the efficiency of management.

Related Theories

Internet of Things is a new research in the field of Internet. In IOT billions of objects can communicate, recognize and respond without human intervention and it is actually an internet of thing and thing. It has many examples of application in our real life, such as equipment inspection, intelligent fire protection, industrial monitoring, smart tourism, smart home, smart grid, intelligent transport, etc. IOT is the network that connects everything with internet, through various types of information sensor devices, such as radio frequency automatic identification (RFID), microwave

sensor, global positioning systems (GPS) and laser scanner, exchange information, and its final aim is to achieve intelligent identification, location tracking, monitoring and management [3]. Current research projections estimate that within 5-10 years, 100 billion devices will be connected to the internet [4].

WSN is an important wireless technology that has wide variety of applications and provides unlimited future potentials for IOT [5]. Wireless sensor network (WSN) is an important wireless technology that has wide variety of applications and provides unlimited future potentials. A WSN can have from a few to several thousand collaborating nodes with computing, data processing, and communicating components.

Tourism information in the process of advancing, the smart tourism is the advanced stage development. The Internet of things technology used in the tourism industry can accelerate the tourism information; make the tourism more intelligent, make people travel more comfortable.

Design of the Architecture of a new Leisure Agriculture Intelligent System

The Internet of Things is acted as the indispensable foundation link of terminal information sensing and will be given wide application space in the tourism management [6]. The intelligent system of leisure agriculture based on the internet of things completely changed the traditional management mode of tourism and agriculture. The proposed intelligent system for leisure agriculture based on IOT is illustrated in Figure 1. The system consists of wireless sensor networks (WSNs) in leisure agriculture scenic spot, video monitoring equipment, cultivation device, gateway, transmission network and intelligent data center.

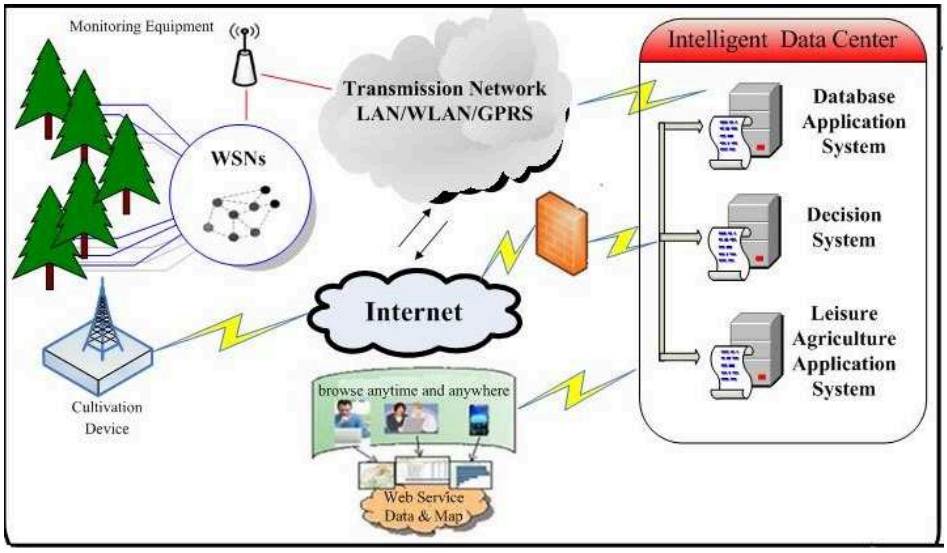

Fig.1 The architecture of the new leisure agriculture intelligent system

WSNs are composed of a great number of tiny low cost and low power consumption sensing nodes based on Zigbee technology [7]. The node is made up of four main sub modules [6]. The sensing module consists of several sensors chip as humidity, temperature sensor and On-board interfaces for optional sensor; two AA-batteries are used as power supply. The RFID reader interface can connect the RFID reader and complete the RFID cards and labels reading and writing capabilities. A great many such nodes, deployed in the leisure agriculture tourism scenic spot to be detected. The data from the monitoring nodes is transferred to the intelligent data center by the gateway via a transmission network (LAN/WLAN/GPRS). The gateway can realize the seamless access and adaptive switch through WLAN/Ethernet/cellular network.

Cultivation equipment integrated with embedded TCP/IP protocol; access the Internet through wired or wireless way, which can perform the breeding strategy on by remote control. When the Cultivation equipment receives the control command from remote intelligent center, it will make

response, such as adjusting the light intensity and irrigation time. Video monitoring equipment can transport the scene of the leisure agriculture parks in real time.

The intelligent data center analyzes and processes the plant growth quality parameters, combine with the expert decision-making system, providing support for the grower and tourist to better understand, then real-time tracking, make cultivation strategies or control, who get the information via the internet anytime and anywhere, how each factor affects growth and how to manage maximal crop productiveness. It can realize to move the physical world of farmland into the network, then manage real-time online through internet.

The intelligent data center software platform frame is shown in figure 2, which based on Struts, Hibernate, Spring Framework for J2EE technology, designs each module function of the system according to the idea of modularization. And using the method of system engineering, combine with the multiple subsystems, forming a reusable, extensible and replicable system. It includes main three parts: the leisure agriculture application system, database application system and the decision system.

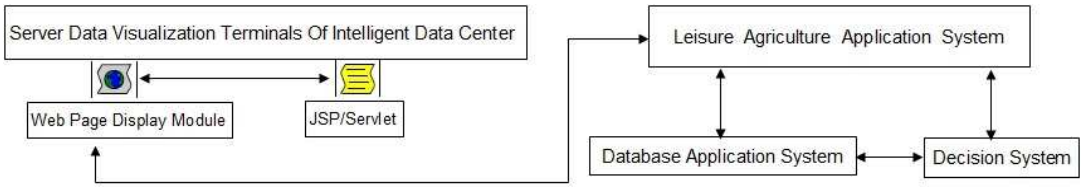

Fig.2 Intelligent Data Center Software Platform frame

The leisure agriculture application system faces to users group; this system is used for collecting new data and shows out in the website form. It can build a stable and safe bridge between intelligent data center and gateway. The database application system is used for classifying and saving the different information in the database. It mainly has three son databases: the information from leisure agriculture farmland son database, the information of communication son database and the user information son database. This system stores the data, then provides to other applications. The decision system mainly collects agricultural domain knowledge, intelligent system model and expert experience, which provide advisory services to agricultural production and management, guide the scientific farming.

Design of the leisure agriculture application system

The leisure agriculture application system includes four parts: Server data visualization terminals, data transmission module, data collection transfer module and the backstage management module. The server data visualization terminals include web page display module and JSP/Servlet. The server data visualization terminal is one part of the leisure agriculture application system, which are the interface of user and the intelligent data center.

The data transmission module includes the tripartite function mainly: Building connection element; receive data and upload element; dispatching terminal data element [8]. The data collection transfer module is mainly responsible for connecting database application system with customer data display web page.

The web page display module is used to demonstrate relevance information, which function structure chart is shown in figure 3. This module introduces the factory pattern, analyze and expand it. Based on the module, users can make online planting plan and implementation, realize remote real farm management via the Internet, and according to their own favor and need to choose the field of personalized cultivation; when the user is planted in the network, the real farm will have staff on-site service, thus it can combine virtual and reality. After planting, the customer can browse the growth of their crops and cultivate their farm online. Of course, the user can also choose to plant personally on-site in the farm. It not only enrich the farm, but also can loosen body and mind, o achieve the combination of leisure and entertainment. When the crop is mature, can be obtained by way of self pick or entrust, comfortable taste of green food.

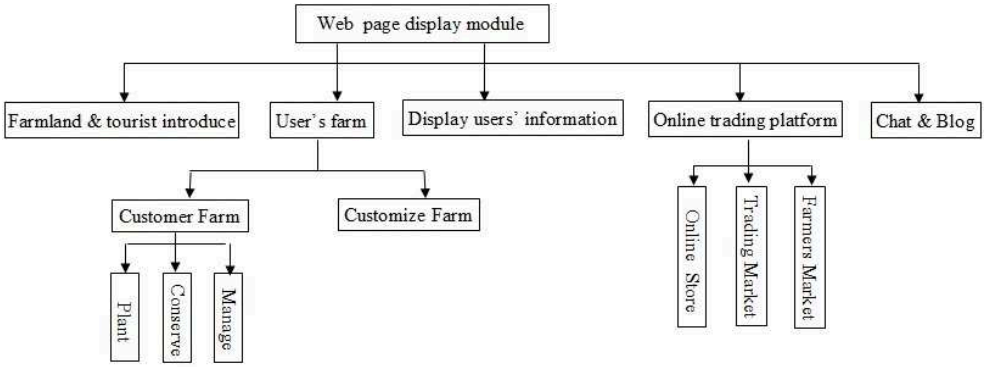

Fig.3 Web Page Display Function Structure

Conclusion

With the development of intelligent agriculture and smart tourist application of the Internet of things, based on the Internet of things the new leisure agriculture intelligent system can remote manage the reality farm, browse the live of the farm, combine virtual and reality. Therefore, based on the Internet of things the new leisure agriculture intelligent system has very big prospect and space on intelligent leisure agriculture.

Keywords: sports; E-government; development platform; technical framework; functional framework

Abstract. Constructing sports e-government platform is an important content that all levels sports departments carry out sports optimal allocation of resources, expand the development and use of sports information resources and to improve the level of development of sports undertakings. For difficult problems in the construction of sports e-government platform, this paper studies the technical framework and functional framework. The technical framework is composed of seven sub-systems that Infrastructure layer, Database layer, Basic components layer, Core services layer, Application system layer, Portal layer, Access channel layer and so on. The functional framework is composed of five sub-systems that Sports information distribution system, Sports transverse application system, Sports office automation system, Sports management information system, System maintenance management system and so on. Contents of this paper focus on improving the level of application, government information resources development and utilization as the main line, for enhancing sports work management, promoting the development of sports undertakings plays an important role.

Introduction

E-government is the application of modern information and communication technology, make management and services through network technology integrate, on the Internet to implement optimal reorganization of the organizational structure and workflow restructuring, Beyond time and space and the separate limitations of departments, to provide quality and comprehensive, standardized and transparent, in line with international standards of management and services [1, 2] to the society. With the development of information technology and application level awareness continues to improve, many local governments to upgrade and update the system, adding a new operational rules and regulations, strengthen inter-departmental coordination between regions, promoting development of China's sports undertakings.

With the development of software development technology, in multi-software development project, reusable, easy to expand, and is well-tested software components, more and more people favored. It will be ample time to analyze, build on the application of the business logic, rather than the code works complex [3]. So make same type of problem solving approaches abstract, extraction into an application framework, that framework are some proved through practice, it can be used to develop technology of highly efficient application systems, through the design and application of the framework to achieve the control software to improve the quality of software production efficiency. For existing problems in the sports e-government construction process, this paper studies its technical framework and functional framework to provide support for system construction.

Technical Framework

Technical framework is the basis of the framework supporting software development; developers accomplish specific business processing functions on the technical framework. Sports e-government technical framework is composed of Infrastructure layer, Database layer, Basic components layer, Core services layer, Application system layer, Portal layer, Access channel layer, Safety and security, Management and regulation and so on. The structure is shown in Fig. 1.

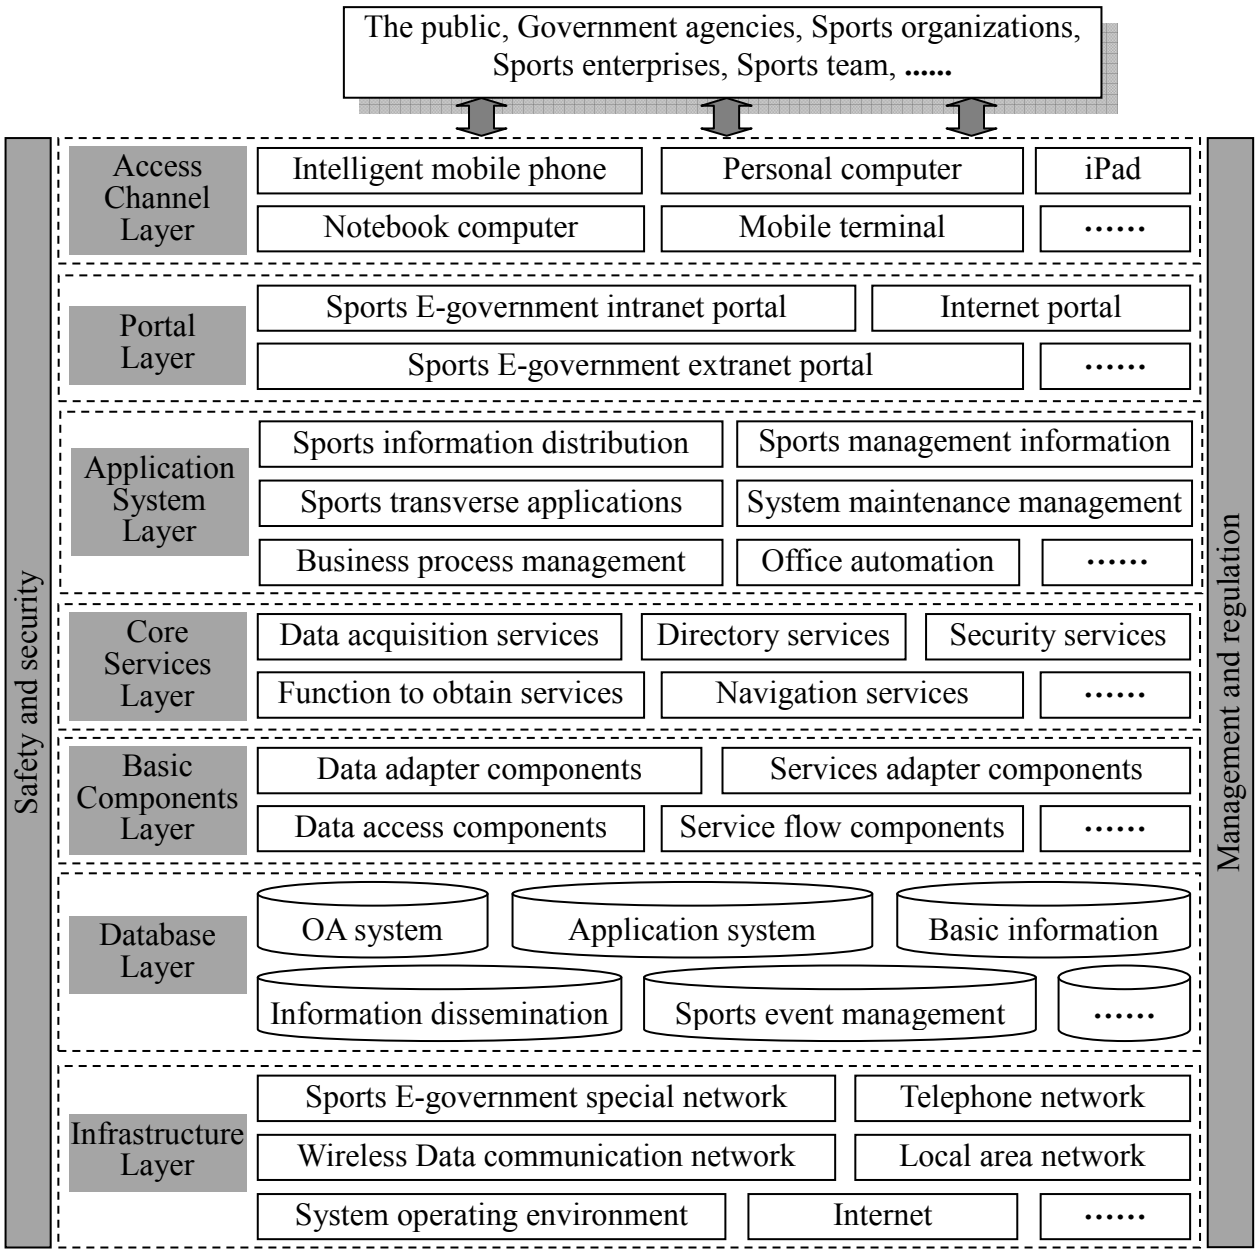

Fig. 1. Technical framework on sports E-government platform

In Fig.1. each layer is described as follows [4,5]: Infrastructure layer, provides support for the system operation, including data communications network infrastructure, the system runs the software and hardware environment; Database layer, various data storage system operation, the database management system and the various databases configured; Basic components layer is encapsulation of data and methods, you can drag and drop programming, fast processing and properties of the real object-oriented design; Core services layer, providing a variety of different applications for different services, including search services, and intelligent search engine services, data acquisition services, features access to services; Application system layer, the functional departments building e-government applications including functional departments of internal office systems, vertical industry applications, cross-sect oral leadership-oriented applications and integrated decision support systems; Portal layer, e-government portal is a variety of applications in various application systems integration and deployment platform components, the different functions of each system to effectively organize themselves to provide a unified entry information publishing and services for all types of users. Access channel layer, the user can use a variety of terminal equipment, through a variety of access channels to achieve any person at any time, any place can enjoy Licenses personalized e-government services; Management and regulation,

including dedicated e-government standards and comprehensive standard specification of existing IT two parts, it is to ensure that e-government application system design, construction and operation comply with the relevant standard security system.

Functional Framework

Combined with results of previous studies [6, 7], sports e-government platform functional framework shown in Fig. 2.

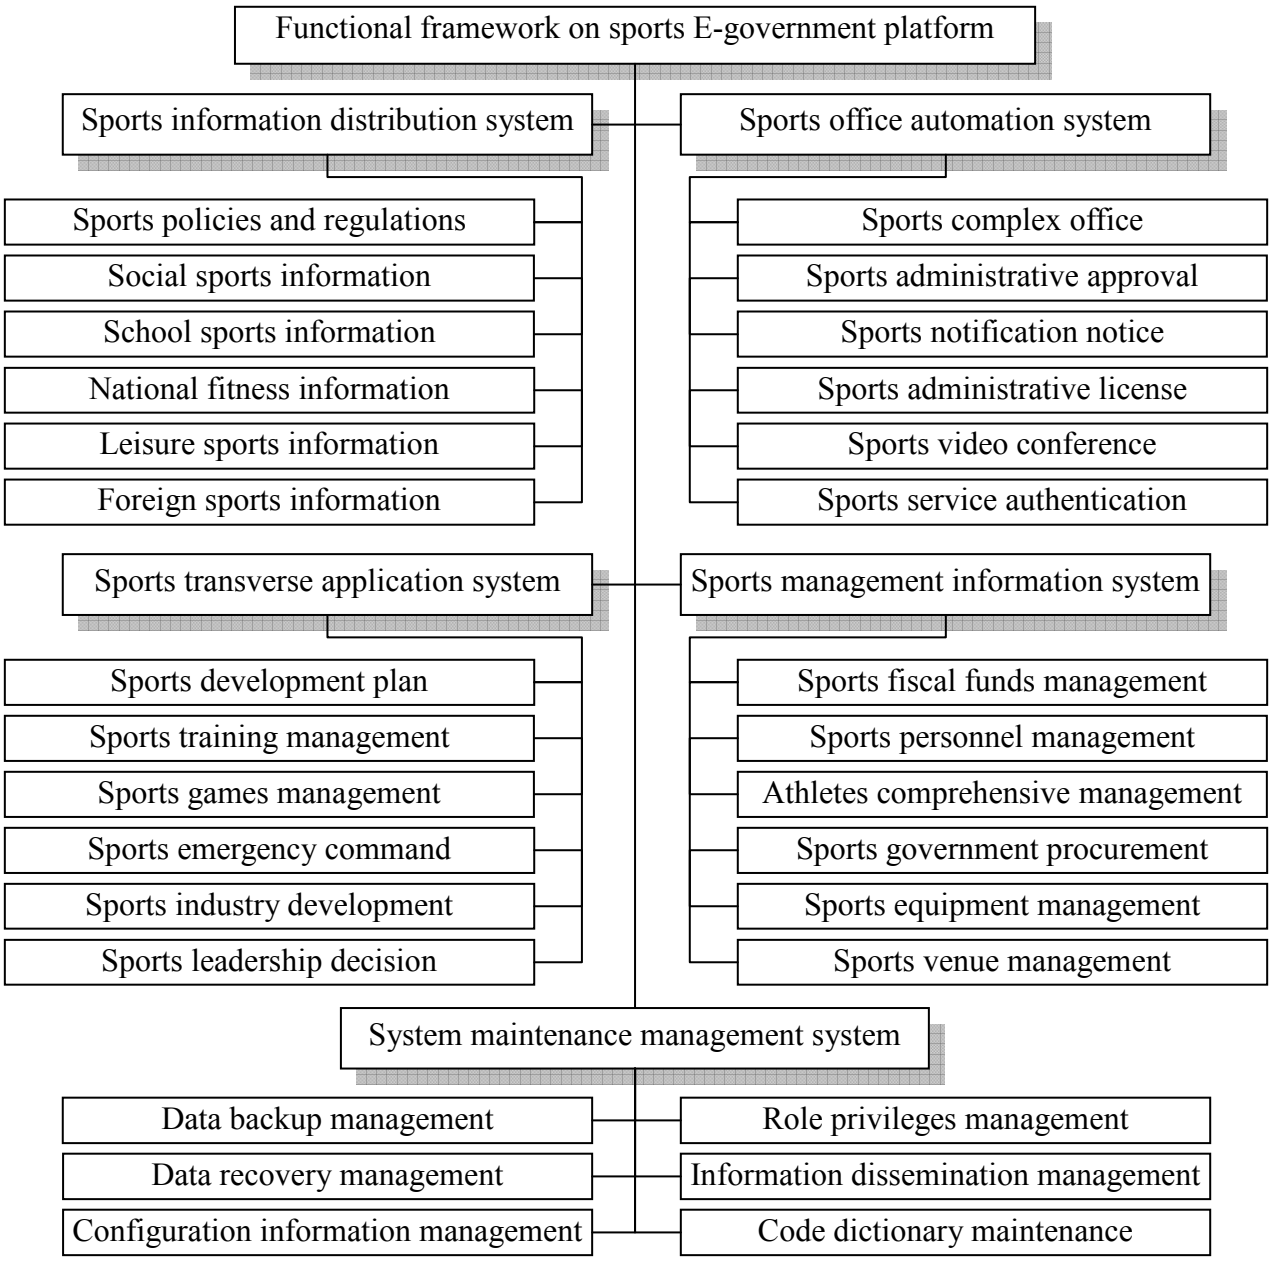

Fig. 2. Functional framework on sports E-government platform

For a brief description of each function in Fig. 2. as follows: Sports information distribution system, it integrated diversity and vivid multimedia video information, and achieved remote centralized management and content of the new information published at any time, so that the audience for the first time to receive the latest information on all kinds of sports, not only to provide timely, comprehensive, high quality and efficient information services and the new sports culture, but also can greatly enhance the overall image of the sports management department; Sports transverse application system, combining sports and generic e-government actual situation, depending on the sports management department of information technology related guidance on the

development of scientific and rational information system implementation plan, to avoid duplication and investment, primarily to establish a collaborative management system covering business areas; Sports office automation system, using Internet / Intranet technology, based on the concept of workflow, the internal staff to quickly and easily share information, work together effectively to achieve a full range of information collection, information processing, to provide a scientific basis for government management and decision-making; System maintenance management system, only to do system maintenance, sports e-government platform that has the vitality of a planned, organized and carried out the necessary changes to the system to ensure that the various elements of the system along with changes in the environment is always in the latest, correct operating state [8].

Conclusion

Implementation of e-government is the focus of the national information work; it is an important measure to deepen administrative reform. The main purpose of sports e-government construction is to promote sports management department office automation, network, electronic, use of information technology to break the organizational boundaries of sports executive, establish electronic virtual office to achieve widespread sense among government departments and government and sports communication between the community and contact information [9]. Sports functional framework and technical framework of sports e-government platform in this study, it focus on improving the level of application, government information resources development and utilization as the main line, establish mechanisms for information sharing and business collaboration, focusing on improving social management and public service role, for better enhancing physical work management, promoting the development of sports, and then stimulating development of information technology has an important role.

Keywords: boost, CIP, portable

Abstract. The paper explains the Ethernet/IP and CIP communication protocol and its application in the industrial automation systems, and designs a software system based on many construction cases,which can be transplanted to variety of the medium.

Introduction

In the industrial automation systems, network management need to control the internet in real time, and get the production process data in order to meet the different needs of management. Since DCS, PLC and other intelligent instrumentation in the control line often from different factory, so the communication between each other is very complicated. Because of the less flexible communication interface , traditional automation systems which is based on the communication between the network and data management leads to low flexibility and bad extension.So that, How to effectively get the data needed in the management of internet from the control network, is an issue of common concern in enterprise automation implementation process.

As the industrial portable communication software, which can implement the data collection and data confusion.This involves three problems: the communication protocol, the design of data collection server software, and the software design of data collection of client terminal.

This software to imitate the OPC of C/S architecture ,and can provide the function of OPC, but the communication method of the client and server use and implementation is different from the existing OPC design[5].

Portable Software Design

Software portability is refers to the code can be transplanted between different platforms; hardware portability refers to transplant between different hardware (such as different CPU architecture). To be able to obtain a wide range of code portability, two aspects need to pay attentions. First is the selection of the development of language. Currently, all interpreted languages, such as Java, etc., based on the design of its managed execution, are able to have a good portability [2,4]. However, its disadvantages are also obvious, because of the need to have the support of the Java virtual machine, its performance is poor, so it is difficultly to meet the need of data exchange industry. Therefore, This software uses the language is a standard C+ +,G++ compiler and some C++ library STL, Boost, etc. Since the industrial software commonly uses C++ language, so that makes the code developed for a wide range of portability and the costs are relatively small.

Another need to avoid the problem is to avoid using platform in the program directly related API functions. For example, if you use too many Windows API functions in the program, when the program transplanted to Linux direction, will be very difficult. So, this software enables logical separation of the data access and data entity tiers. Commonly used API is packed into DLL module for using the functions of the device by particular interface in experiments.In other parts of the software, you only need to call these defined interfaces. As the porting software, each of the modules is

independent so that the user can amend and perfect any incomplete module according to his requirement without influencing the function of the others.

Based on the idea of design is proposed,the paper selected C++Boost libraries ,Boost library for these platforms,so that files,or network communications,or thread can be managed from an API. This software embodies the portable design idea, and has been successfully applied to several projects. This means that the code for these applications does not have to be changed or recompiled to run in compatibility mode.

Software Design

Overall Architecture. Based on distributed design, this software is divided into two parts: client and server, each part of the process runs as an independent. As the core of the software, server is in charge of protocols package of Ethernet and TCP/IP, and communication with equipment. Server processes these requests and also communicates with the back-end server to gather the necessary response data[1].

In the software design, the design plan and function are given and all server programs were completed by C++ language. In the network communications and multi-threaded processing, based on the principle of reducing the correlation system, the Boost IO libraries can be called.

With good human-computer interface feature, this software can display various data completely, such as: specify the data device, select the data points, observations, and so on. Communications between the client and the server can be configured according to the requirements of customers. If the server program and client program running on the same machine, the user can choose the way of shared memory communication in order to get the higher efficiency. If the server and client programs running on different machines, the user can select a network socket communication.

The architecture of the software as shown in figure 1:

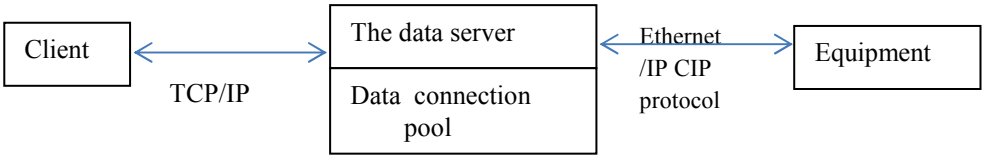

Fig.1. Software architecture chart

Detailed Design

Client /Server interface and Communication. In this software, server participating in communication work in two ways: one of which is accomplish data gathering, the other is complete the data communication. This module allow encapsulation of a piece of functionality in a standalone module with an explicit list of
C ++ functions that are available for external users. Interface of this module,which resembles a OPC standard interface functions, mainly includes adding Group and specify the refresh rate of Group , add or delete item about Group list items , read or write data item data and so on. A client application can call on the module to perform Communication between the server and equipment. This module needs to design a perfect communication protocol, in which client and server group can complete the communication . The system needs to be composed of a series of calls to existing backend databases and commands.

As described in the previous section, there are two ways to complete the communication between server and client :share memory and network socket . According to the the principles of object-oriented programming, communication between the server and the client in the underlying implementation is based on the abstract data flow(stream). According to the user's choice, the software applies it to memory stream or network transmission flow. In order to limit the communication congestion, which can dramatically degrade the system performance, it is

important to using asynchronous IO mechanism, and according to the different usage of the signal synchronous or asynchronous network I/O mechanism.

Realization of data collection service

(1) Ethernet / IP protocol stack and CIP

The server communication protocol stack architecture based on the layering thought. The Ethernet / IP connection layer and CIP protocol layer are designed, and each layer includes a series of class. The following focused on not only the design of key classes and the realization of system's flexibility, but also the realization of key functions.

(2)The management of connection pool

To communicate more than one local area network devices requires an additional module, such as connection pool , which ensure a connection for each communication equipment correspondence in the pool. The connection will be automatically deleted as soon as the connection pool without any data transmission over a period of time to decrease overhead and increase performance, references are timeout management mechanism.

(3) The management of data pool

Typically, data collection program communicates with the hardware equipments according to the refresh rate specified by the client, and gets the value of some of Tag. Because of some changes in the Tag value may be very frequent, and contain a lot of noise. This software, like the OPC standard ,provides user subscription service[3]. The client software is usually only need to care about its value exceeds a certain threshold. That is, the service provider will need access to the parameters given by the customer to determine where to send the response to the client. So, we need to cache data from a database or other backend data store that needs to save the certain historical data, up to achieve the above purpose. In order to achieve efficient data search, the data pool is based on the connection, that is to say, each connected active and equipment room, will be corresponding to a data pool. Simple codes as follows:

```
server = new DataServer();
error = server->Connect(addr);
error = server->AddGroup(group.Handle, group.Rate);
   BOOST_FOREACH(Item&item, items)
{
Item.GroupHandle = group.Handle;
}
error = server->AddItems(items);
for (int i = 0; i < 1000; i++)
{
  error = server->WaitUpdates(C__INFINITE);
  ItemUpdate buffer[100];
  int n = sizeof(buffer);
  error = server－>ReadItems(&n, buffer);
   // parse the buffer and output result…….
}
Server->DeleteGroup(group.Handle);
Server->Disconnect();
```

Software operating results

Finally, create a simple client program under Linux platform to test software. After running the client program and provide the necessary parameters, it can get a value from the server regularly. Operating results shown in Figure 2.

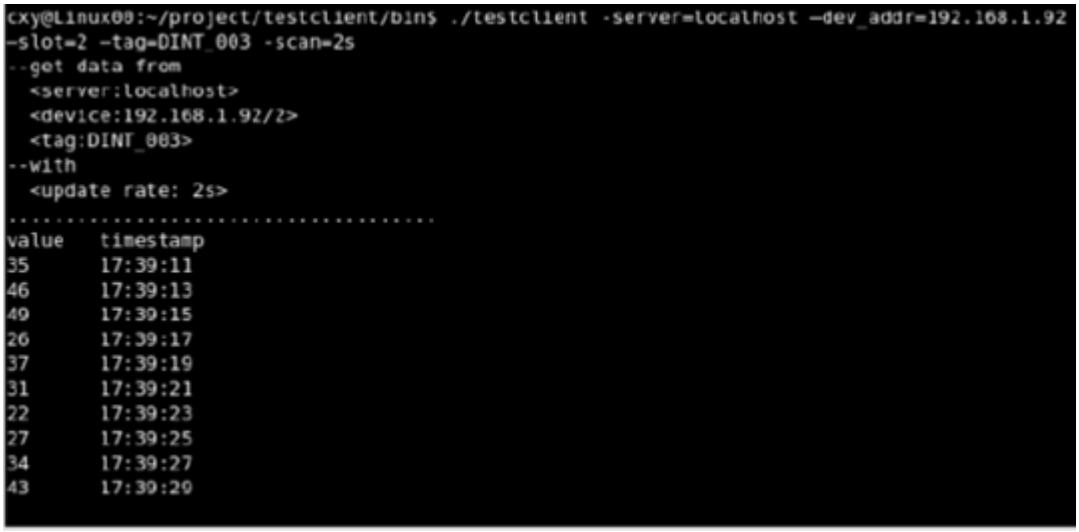

Fig. 2. Software running effect diagram

Conclusions

This paper describes some key techniques in design and implementation of portable software system, including the realization of interfaces and communication module, which makes portable industrial communication software possible. Future will further study on how to develop OPC server under Linux.

Design and analysis of a reliable group signature scheme based on discrete logarithm

Hongli Wan[a], Guijuan Song[b] , Yanhui Chen[c]

Dalian Neusoft University of Information

[a]wanhongli@neusoft.edu.cn,[b]songguijuan@neusoft.edu.cn,[c]chenyanhui12@nou.com.cn

Keywords: Discrete logarithm, Group signature, Signature scheme.

Abstract. Through the analysis, a group signature scheme based on discrete logarithm is put forward in this paper. strengthen the validation of the members when they join the group; Records the time stamp of the revoked member into the database, to prevent the forged signatures; To recognize the forge the signature of the revoked and illegal members. Finally, analysis shows the scheme satisfies correctness and security.

Introduction

In 1991, the group signature scheme is put forward for the first time by Chaum and Van Heyst [1]. This scheme allows group legal members signature in the name of the group. The administrator can reveal the signer when dispute occurs. A security plan should be non-forge ability in addition to anonymity, trustworthy and Coalition-resistance [2-5]. All the group members cannot forge a valid group signature; the revoked members can't signature with previous legal status [6-9].

Through the analysis, a group signature scheme based on discrete logarithm is put forward in this paper. strengthen the validation of the members when they join the group; Records the time stamp of the revoked member into the database, to prevent the forged signatures; To recognize the forge the signature of the revoked and illegal members. Finally, analysis shows the scheme satisfies correctness and security.

New Signature Scheme

This scheme includes three entities: Certificate Authority (CA), Group Member and Group Administrator. The mutual information between CA and group members will be validated by signature algorithm. The algorithm has a certain security because of the discrete logarithm.

System Establishment

Assuming the group center is trusted. It chooses two max prime numbers p and q secretly, and a public hash functions $H(.)$. Let $n = pq$, $\varphi(n) = (p-1)(q-1)$. Random select an integer $e < \varphi(n)$. Meet the condition $ged(e, \varphi(n)) = 1$. Calculate the integer d, meet the condition $ed = 1 \bmod \varphi(n)$. The public parameters of CA are *n* and *e*, the private parameter is *d*.

Add Member

When the *n+1* member want to join the group, firstly, choose a integer $e_(k+1) < \varphi(n)$ randomly, meet the condition $get(e_(k+1), \varphi(n)) = 1$, calculate the integer *d*, meet the condition $e_(k+1)d_(k+1) = 1 \bmod \varphi(n)$. Use the $e_(k+1)$ as public key, the $d_(k+1)$ as the private key. The number *k+1* member applies to the group center, sends $e_(k+1)$ to CA. After CA to verify their identity, the identity ID of $e_(k+1)$ and the *k+1* member are stored in the database.

Delete Member

To delete member *i*, calculate $y_i = (ID_i)^{d_i} \bmod n$. Member *i* will send the $Sig(ID_i)$ and the withdraw application to the CA together. CA verifies the identity of the applicants:

$$Ver(ID, y) = TRUE \Rightarrow y^{e_i} = ID_i (\bmod n) \quad (1)$$

CA use the formula (1) to verify the membership of group member *i*. if the result is true, then validation passes, the cancel application is made by group member *i*. CA will set the abolish timestamp of the information map (e_{k+1}, ID_{k+1}) as the current time in the PB.

Generate signature

Group member *i* signs for message m by the sign secret key d_i, calculate: $y = (m)^{d_i} \bmod n$, send y_i and message *m* to CA. CA verify the legitimacy of the identity, then verify the correctness of the signature using the formula $Ver(m_i, y_i) = TRUE \Rightarrow y^{e_i} = m (\bmod n)$. If the result is true, the signature is correct and send by member *i*, CA will send signature *y*, ID_i and the signature timestamp to the group administrator. The group administrator will record it in the signature list, in case of a dispute open signature use in the future.

In order to prove that the CA has reviewed the signature, CA will sign on it:

$y_{CA} = (m \cdot ID_{CA})^{d_{CA}} \bmod n$. Then y_{CA} will be sending to group member *i* by CA.

The member will send the final signature (y_i, y_{CA}) to the signature receiver.

validate signature

CA is trustable; the group member who receive the signature will validate the signature by the public key of CA:

$$Ver(ID_CA, y_CA) = TRUE \Rightarrow y_CA \wedge (e_CA) = ID_CA (\bmod n) \quad (2)$$

If the verification passes, prove that the signature has been approved by CA, and has been recorded in the CA database. Here, to verify the signature is correct, and issued by CA：

After verification of $Ver(ID_i, y_i) = TRUE \Rightarrow y_i \wedge (e_i) = ID_i (\bmod n)$, proved that the signature is generated by the legal group member *i*.

Open signature

When the dispute occurs, need to open the signature. Send the signature to group administrator, the administrator will verify the signature is generated by the legalgroup members through the formula(1) and the information stored in PB. If the signature is send to administrator, the administrator will search the signature list, find the ID_i of the corresponding signature, then send the ID_i to CA. CA sends ID to the requester who open the signature.

Scheme analysis

Correctness

Based on the discrete logarithm, If the signature of *Y* received by CA is produced by the legal group members according to the algorithm, then the signature can be verified by CA.

Prove:

Only the signature verified by formula (1) can be recognized by the CA.CA calculation process is as follows:

Premise: $e_i d_i = 1 \bmod \varphi(n)$; $y_i^{e^i} \equiv (ID_i)^{d_i e_i} \bmod n \equiv ID_i (\bmod n)$

Therefore: The formula was established, CA can confirm the legal status of members.

Prevent forgery attack

When the user *i* cancellation, CA will let the abolished timestamp of the information map (e_i, ID_i) as the current time in the database. If other members forged the signature of *i*, will be identified.

Prove: proof by contradiction, Assume that the user can forge a signature; the signature will pass by CA validation. CA validate the signature of user *i* by formula (1), the forger *j* resolve the private key of member *i* successfully. That is forger *j* resolve the discrete logarithm problem; this is conflict to the fact that the discrete logarithm is intractable. So, if the other members forge the signature of *i* after the member *i* sign out, it will be distinguish. QED.

Above is analysis of revoked member forge legal signature. For all the illegal members, to forge the member's signature, have to work out the private key, which solves the discrete logarithm problem. Because of the discrete logarithm is hard, so any illegal members can forge the signature of legitimate member *i*.

Conclusion

This paper proposes a group signature scheme based on discrete logarithm. Members to join the group, strengthen the validation of the members. Record the timestamp of the sign out member in the database, prevent its signature was forged. Be identification to the sign out member and all the other illegal members. Finally, analysis the scheme satisfies from the correctness and safety. When the group member withdraws, only record its timestamp, but do not update the private key of other group members, to improve operation efficiency.

The Solution of Safety of Electronic Cash in E-Commerce under Cloud Computing Environment

Songjie Gong, Liping Zeng

Zhejiang Business Technology Institute, Ningbo 315012, China

zengliping1208@163.com

Keywords: cloud computing, electronic commerce, electronic cash, safety.

Abstract. Electronic commerce system is now developing at a huge speed, whose final objective is to electronize every phase of commercial activity. Electronic payment is the heart of electronic commerce. Along with electronic commerce development, electronic cash payment systems are also developing. How to achieve safe electronic transactions is the key to the development of electronic cash payment systems. There are two kinds of electronic cash system, on-line and off-line. As the security and effective electronic payment system has become an important part of electronic commerce, according to the new character of cloud computing, it can solve the problems that the electronic cash systems exist leakage of privacy, non-standard transactions and high cost in the traditional network. The paper describes the types of electronic payment and discusses the electronic cash payment safety based on cloud computing. The presented solution can reduce the hardware and software systems cost, particularly for the current electronic commerce security, with efficient and convenient interactive response to the trend.

Introduction

Electronic commerce is to the Internet as a platform, formed through the integration of business information, business flow, logistics system and the payment system of the new business operation mode, can also think that electronic commerce is e-Business. Electronic commerce is an important part of the electronic payment system. Technically speaking, the most critical problem in the electronic commerce is how to achieve the safe payment functions, and ensure the security of the parties to the transaction. Therefore, online payment security and efficiency is the key link of the electronic commerce, electronic commerce is the fundamental condition of the smooth development of.

The so-called electronic payment, refers to the parties to the transaction by electronic means, such as bank electronic deposit system and electronic clearing system to record and transfer of funds, electronic payment is the key part of electronic commerce, the electronic payment is the key link in e-commerce, because of the different mode of operation, various payment systems different characteristics in the aspects of safety, risk and efficiency of payment. But the real money is more convenient, effective. In its simplest form, consists of three main and four protocols. The three parts is the business, customer and bank; four security protocols is initialization protocol, withdrawal protocol, payment agreement and deposit agreement.

As the security and effective electronic payment system has become an important part of electronic commerce, according to the new character of cloud computing, it can solve the problems that the electronic cash systems exist leakage of privacy, non-standard transactions and high cost in the traditional network. The paper describes the types of electronic payment and discusses the electronic cash payment safety based on cloud computing.

Electronic Payment in E-Commerce

Electronic payment is to the business of electronic tools and all kinds of electronic money as the media, computer technology and communication technology as a means, realize the flow of capital and payment in computer network system.

Electronic payment system based on credit card

In this system, consumers first in the bank to have the credit card number and password to open an account. When consumers in the open network environment for shopping or service, he need your credit card number and the password is encrypted and transmitted to the merchant, through the Internet, and then forwarded to the bank by the merchants, and then in accordance with the special protocol for online payment. The model is shown in Figure 1.

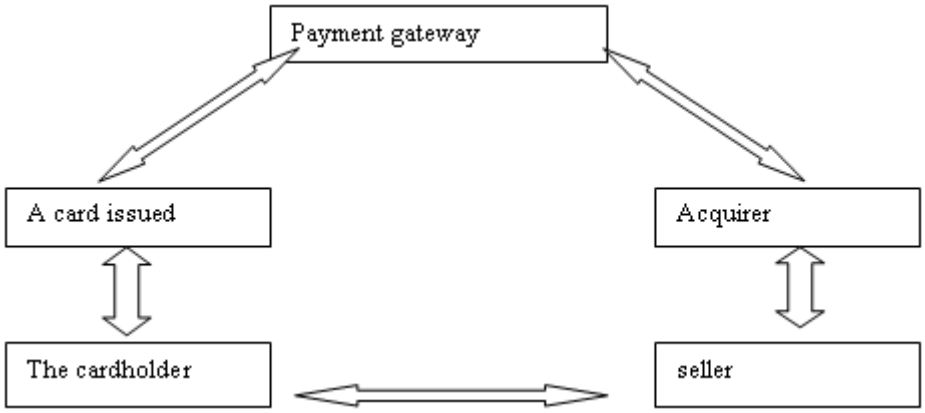

Figure 1 Electronic payment system based on credit card

Payment system based on e-cash

Consumers to open an account in the provision of electronic cash service bank, and pre deposit funds, so as to achieve the same electronic cash and cash value (usually memory smart card or a pure form of electronic hard disk file), and then use the electronic cash terminal software download to your computer hard disk backup, to pay subsequent purchases cost, electronic cash bank businesses and authorized finally received the consumer electronic cash settlement, the bank will consumers to purchase goods or claim service fees to merchants, the model shown in figure 2.

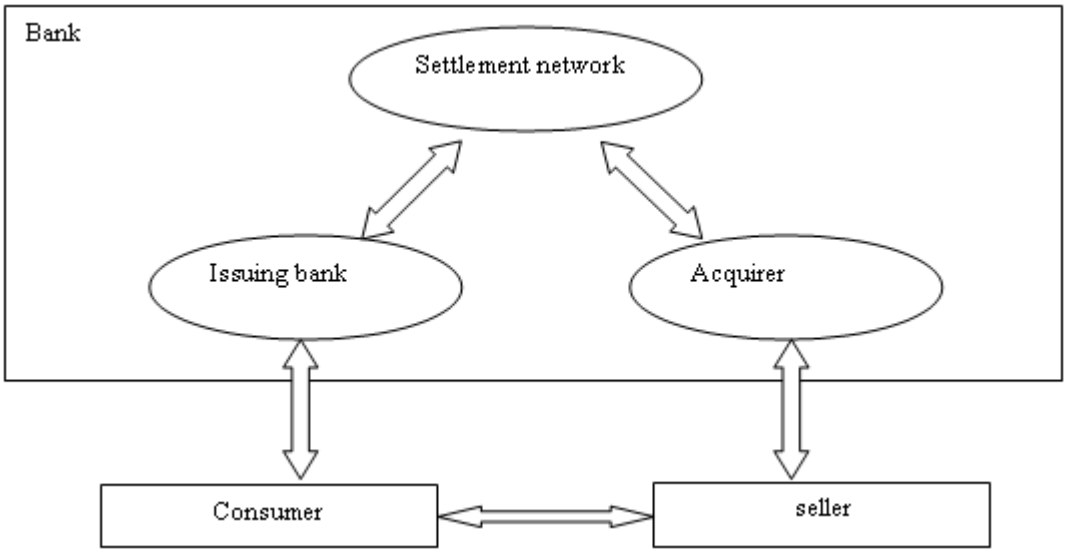

Figure 2 Payment system based on e-cash

Mobile payment system

Consumers through mobile phone wireless internet access browse the service provider's Web site, produce the order information and the digital certificate, payment information to the service provider. Service providers will consumer payment information for payment gateway, and a payment gateway transmits it to the financial institutions. The model is shown in figure 3.

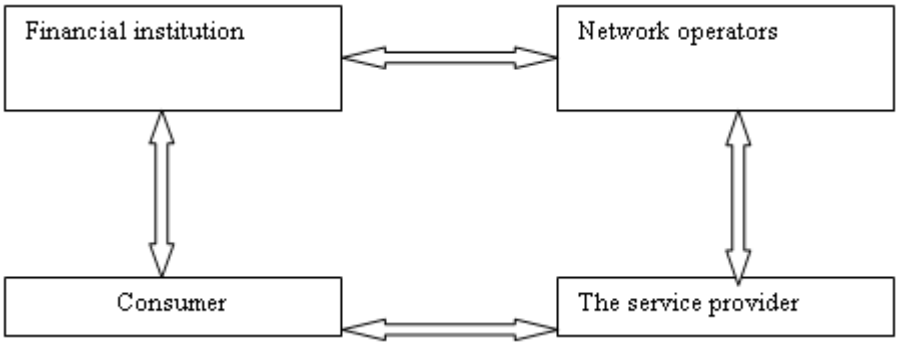

Figure 3 Mobile payment systems

Safety of E-Cash in Cloud Computing Environment

The solution of participation in the main banks, businesses, users and cloud service providers, terminal system and assume that all subjects are embedded in the electronic commerce module. A group of several cloud of electronic banking, by a cloud service provider management, any one bank can issue electronic cash. Business users and can not in the extraction and deposit the same bank electronic cash operation. The model is shown in figure 4.

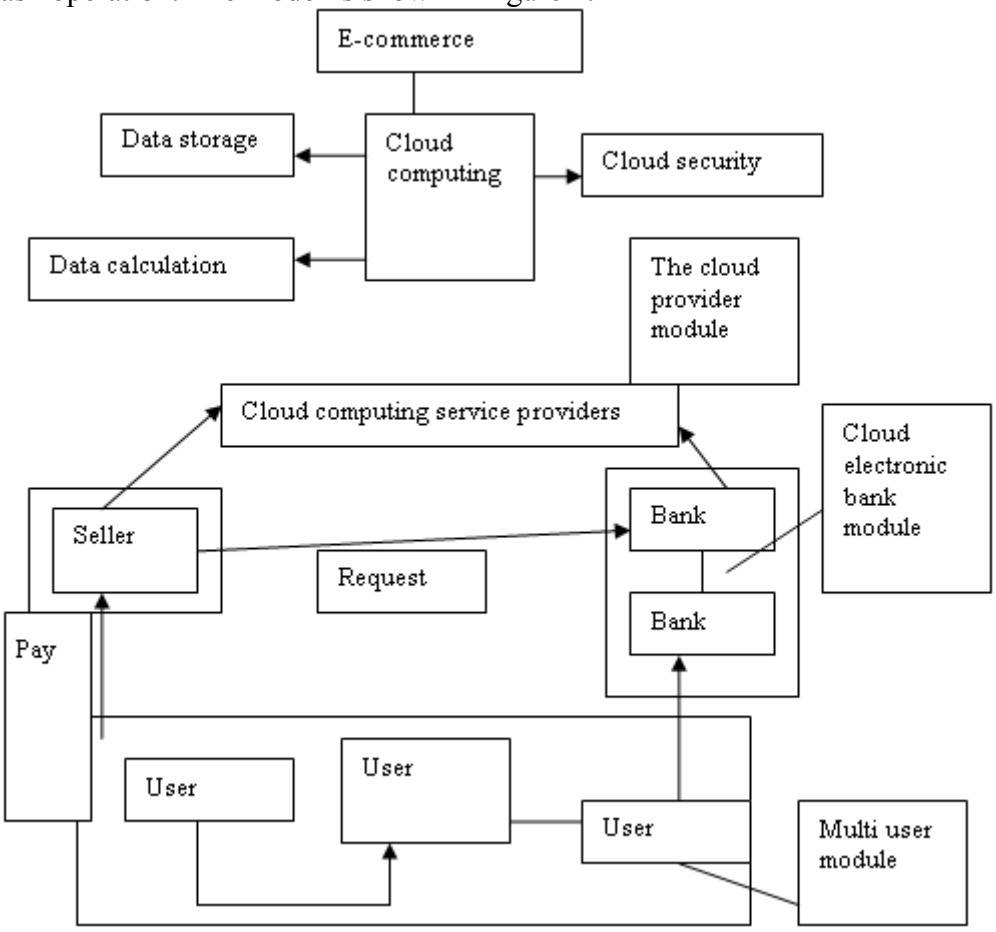

Figure 4 Safety of E-Cash in Cloud Computing Environment

Cloud computing electronic commerce electronic cash model environment are as follows:

1) Cloud electronic bank module: many electronic bank formed groups, group manager GB Bi, group member, and the group of public and private key pair (PK-Bi, SK-Bi). The module has the function of deposits and withdrawals.

2) The user module: formed by multiple users, groups, group manager GU. The user Ui (your bank Bi), platform attestation identity key AIK (PK-AIK public key, private key SK-AIK), the identity of the user's ID IU, and the system terminal of each user with an embedded TPM module is used to protect the terminal security.

3) Business module: business S (your bank Bj), the public and private key pair (PK-S, SK-S). Businesses in order to reduce the cost, hire a cloud service.

4) The cloud service provider module: a cloud service provider for businesses and banks offer cloud services.

5) Encryption scheme subject interaction by using E representation.

6) Security system under the cloud computing environment.

7) Security system of electronic payment in electronic commerce.

Summary

In this paper, it describes the types of electronic payment and discusses the electronic cash payment safety based on cloud computing. The presented solution can reduce the hardware and software systems cost, particularly for the current electronic commerce security, with efficient and convenient interactive response to the trend.

On the China Tourist Hotel E-Business management

Feilong Liu

School of Economics and Management Hunan Institute of Science and Technology, 414006,Yueyang,Hunan, China

E-mail:liufeilong12@126.com

Key words: China; Tourist Hotel; E-Business; operating models

Abstract. Along with the market competition intensifying, the hotel industry has begun to pay more attention to how to create new competitive advantage to increase or maintain the hotel's comprehensive competitiveness, and the development of modern information technology, to create new competition carrier for the hotel industry, so the Tourist hotel to implement electronic business management is the trend of The Times. At present China's hotel industry to carry out the practical effect of electronic business is far from the ideal requirements compared. From three aspects to build and perfect the hotel e-Business is the overall framework of the management model is very necessary: one is set up and improve the customer relationship management system as the center, based on hotel resource planning system of hotel management information system; Second, supply chain management system, set up and improve the hotel in order to realize the hotel e-business B to B mode; Three is to establish and perfect the hotel website or homepage, build hotel network e-business platform to achieve the hotel e-business B to C mode.

For over 30 years reform and opening up, China's hotel industry obtained rapid development. So far, according to statistics, China has reached about 15000 star-rated hotels, there are several times in this hotel. As a whole, China's hotel industry has been in a state of oversupply. Between competing for customers, improve occupancy rates, hotel has become very competitive. In the process of operating practice, restaurant operators have become increasingly aware that competition is the purpose of profit, and not at the expense of profits for the improvement of occupancy. And the product price discount and is no longer the most effective way to the hotel to expand patrons. Price competition as the main means to obtain competitive advantage has clearly not adapt to the reality of the current market development. Therefore, the hotel industry has begun to pay more attention to how to create new competitive advantage to increase or maintain hotel's comprehensive competitiveness, so as to gain higher than the industry average profit margins.

In an increasingly tend to be more open environment, the management of the hotel will be more detailed content, The network can greatly simplify and standardize all of this, but also can greatly reduce the cost. In addition, as an important component of the tourism industry, hotel industry also must try to blend in their whole business chain, more through the network to expand the business. Hotel must be able to grasp at any time from the customer's need, and can meet the needs of all kinds of personalized, only to set up and improve the modern hotel electronic business management system, to make the hotel to adapt to these troublesome and require absolutely in a timely manner the needs of the hotel management operation.[1]

E-Business and its basic characteristics

we usually discuss the e-business generally refers to a way of using the Internet for business activities. From the macroscopic view, E-business is a direct product of information technology led to the network revolution , is the establishment of a new economic form networks through electronic means. It involves not only IT and business transaction itself , but also involves other levels , such as government, finance, education and other social . From the microscopic point of view, e-business refers to the ability of various entities with commercial activities , such as production companies, commercial enterprises , financial institutions, government agencies, individual consumers using advanced computer and network technologies in the commercial trade activity , is a specific form of IT enterprise applications.

Internet itself has an open , global , low cost, high efficiency, also an inherent feature of e-business and e-business far beyond making as a new form of business has value , it will not only changing the enterprise itself production, operation and management activities , and will affect the operation and structure of society as a whole economy. In particular, e-commerce has five basic characteristics:

First, the traditional e-business business process digitization, on the one hand to the digital stream instead of real logistics, can significantly reduce the manpower, resources, reduce costs ; on the other hand it can break through the restrictions of time and space, so that you can in any trading activities time and any place , which can greatly enhance the efficiency ;

Second , e-business they have to open and global nature , able to create more trade opportunities for businesses ;

Third , e-business allows businesses to cost close to enter the global electronic marketplace , making it possible for SMEs and large enterprises have the same information resources , help to improve the competitiveness of SMEs ;

Fourth, redefines the traditional e-Business business and circulation patterns , reduce intermediate links , so that producers and consumers to deal directly as possible, to a certain extent, can change the entire social and economic mode of operation ;

Fifth , e-business on the one hand to get rid of the barriers of time and space , on the other hand can provide a wealth of information resources, it offers more possibilities for the re- combination of various socio-economic factors and factors of production , and thus will affect the community economic layout. With the improvement of the further development of information technology and network infrastructure , e-business will become mainstream business in the form of the information age. Therefore, the implementation of e-Business business management will be its future strategy to create a competitive advantage in important ways and means.[2]

China 's hotel industry to implement e-Business management major problems facing

China 's hotel industry on the application of information technology, time is not long , but now there are many hotels have set up their own business website , or have their own independent website. Many hotel managers also want to quickly improve their competitiveness and economic hotels through e-Business activities , it is actually the lack of a thorough understanding of the overall framework and specific hotel e-Business operation methods. Therefore, the industry believes that the current requirements of the actual results and the ideal e-Business in China's hotel industry is also a far cry compared .

A very real problem is : the application of information technology in the hotel industry offset a widespread understanding, did not really take it as an integral part of the business development strategy , without a profound understanding of hotel e-Business is a systematic project , it involves many aspects of computer hardware and software , hotel property management philosophy and management processes. We find : a considerable number of hotel companies just opened a home page on the Internet , neither the use of web development and integration of various resources , nor conduct business online . Some hotel website or home page for a long time can not update the information , but a lack of hotel communication and interaction with customers , in fact, has become a figurehead for the empty station .[3]

From objective reality , the majority of e-Business service provider fore-businesssoftware and hardware solutions provided by hotel companies can only belong to e-business technology solutions , computer hardware and software systems which simply reflected an overall e-business technology platform concept , service providers difficult enterprise business operations from a specific property characteristics and needs of departure for the complete design and planning. The resulting hotel business e-business applications , can not make the technology platform and business processes to form a perfect combination. In other words , China's hotel business e-business technology solutions based on actual generated e-business application operations management and e-Business software and hardware solutions based on e-business application service provider operating programs are generally difficult to form a perfect combination of form .

To improve measures and countermeasures of Chinese tourist hotel e-business management

Hotel e-business management final solutions from the hotel business and e-business service providers two aspects, but also embodied the two basic elements of e-business. How hotel companies should design and plan their e-Business applications , to finally put forward a set of practical e-business application operation of the program , through the establishment and improvement of hotel e-Business model with universal significance to achieve. Combined with the management of the hotel industry specific reality , in the hotel business and e-Business software and hardware enhanced service providers full communication and collaboration throughout the premise , we can consider the following three levels to build and perfect the Chinese e-business , management and operation of modern hotel the overall framework of the model.[4]

1.To establish and improve customer relationship management system as the center, Hotel Resource Planning -based hotel management information system

Customer Relationship Management system is an important tool for hotel customer resource management. CRM from the hotel at all levels of contact with the customer , the customer's data of all backgrounds and behavioral data collected and together, these operational data , and external market data through the integration and transformation, then loaded into the data warehouse , OLAP and use data mining techniques to analyze and master the relevant laws , patterns or trends from the data. Finally, the hotel Resource Planning , etc., the relevant customer information and knowledge effectively transfer and sharing throughout the hotel . The information and knowledge will translate into strategic and tactical actions hotels , help improve the relevance and effectiveness of hotels across all channels of communication with customers , thus bringing the right products and services , through appropriate channels , at the right time , provided to the appropriate customers.

The so-called property resource planning system, refers to the use of database technology and specialized user interfaces to control processing center hotel business information, is uniform for the entire property transaction processing systems. It features a variety of business hotels such as customer resources, human resources, finance, services, accounting , distribution and other links to a common system, so that the hotel business process management and service data sharing and integration in order to achieve automated transaction processing and customer , financial , service and distribution of resources and effective tracking.[5]

2.To establish and improve the hotel supply chain management system, in order to achieve the hotel 's B to B e-business model

Hotel Supply Chain Management comes to hotels material suppliers , distributors (travel agents , online distributors, airlines , exhibition companies, etc.) , rental companies , scenic (attractions) , and other partners and end customers , is a hotel integrated system of external supply chain management . Under the trend of economic globalization and the development of market integration , the market will no longer be a competitive advantage companies have many material resources , but in their many social resources can be integrated to increase their market competitiveness. Hotel supply chain management system is to optimize and improve the hotel supply chain activities . Hotel Supply chain management is the organization of the supply chain objects (business) and information flow , capital flow and material flow between them. Methods are integrated and coordinated , the goal is to meet the needs of users hotels to ultimately improve the overall competitiveness of the supply chain hotel . Supply chain management is not another name for supplier management , but a new organizational strategies , which integrate the different companies in order to increase the efficiency of the entire supply chain , focusing on cooperation between enterprises. Relevant stakeholders in the supply chain with multiple parties competing relationship led to the arrival of the era of mass customization supply chain has a strong randomness. Establish and improve the hotel supply chain management system enables hotel companies with the fastest speed through the supply chain to effectively respond to the specific needs of customers, the entire supply chain to maintain continuous dynamics , which can more effectively ensure adequate to meet the needs of hotel customers .

3. establish and improve the hotel website or home page , e-commerce platform to build the hotel network in order to achieve the B toC hotel e-business model

Core Hotels is to create a network of e-business through the hotel website building a good network marketing environment , you can always receive hotel reservations around the world and sales information , and feel free to send information about this hotel in order to facilitate the selection and booking guests . This necessarily involves several important aspects : first, online room reservation system ; Second important domestic and international tourist hotels electronics market ; third is to provide property -related information and services ; Fourth, online customer surveys and consulting , as well as mailing lists and forums and other interactive features.

Many hotel managers tools just as a publicity hotel Hotel website corporate image , released hotel advertising , this is a big misunderstanding.Because network marketing is completely different from traditional marketing target object.The main factors involved are traditional marketing 4P, namely product , price , Place and promotion; while in the network environment, the elements involved in network marketing is 4C, that the Consumers Wants and Needs,Cost to Satisfy Want and Needs and to Convenience to buy and communication. Therefore, the positioning of the hotel e-business website should solve problems for customers around the needs of customers to solve problems , rather than according to their own needs to build hotel site, which is a major principle of network marketing. Only under this precondition site targeting , hotel managers will consider such questions in the website content design : layout and offers hotel rooms distribution, electronic map showing location of the hotel and the surrounding environment , the hardware facilities such as room decoration style , bedding and other customers may be asked to change or choose to provide weather forecasts Check for booking customers, to provide pick-up or car rental , hotel or surrounding scenic attractions, providing customers with discount tickets , providing customers with local terroir human introduce major economic and cultural activities and local reports , and so on . Hotel industry is an open industry at different levels , different grades of hotels will have to face different target markets. Hotel impossible to meet the diverse needs of all customers , but must endeavor to provide services to their target customer groups , in order to fully meet their needs.[6]

All in all, only from the above three levels to build and improve the overall framework of Chinese tourist hotel management and operation of e-business model , was better able to form a complete e-business value chain hotel . China 's hotel industry on the application of e-business is still in the exploratory stage, the hotel industry there is not a specific reference to a successful business model . How to effectively use e-business to enhance the competitiveness and economic hotel , hotel business depends on continuous learning and practice.

Keywords: Ceramic Products' Information; Web Information Extraction; Extraction Rules

Abstract. In the means of getting information from the Internet, the Web information extraction technology which can get more precise and more granular information is different from Search Engine, this article presents the technical route of Web information exaction of ceramic products' information on the basis of analyzing the developing status of Web information extraction technology at home and abroad, and makes the extraction rules, and develops a set of extraction system, and acquires the relevant ceramic products' information.

Introduction

With the application and promotion of Internet technology, and the explosive growth of information, the World Wide Web has become the massive information repository. Confronted with such massive data of huge and varying structures, how to get useful information rapidly and accurately from the Internet? The common method is that users look for, according to their requests, a large number of relevant web page information with the aids of well-known SEs like Google, Baidu, Yahoo, etc. . Because the structure of these web page information is different, and the content is independent from the database, the SE crawler can not find the information in the back-end database, so it needs manual interpretation. In order to get more precise and more granular information from the Internet, meanwhile transforms the received crawler information into database, so as to make further analysis, and the Web information extraction technology is born at the right moment.

The information extraction research started in the 1980s, the typical extraction system at that time were Linguistic String System, FRUMP System and ATRANS System[1], etc.; with the prosperous development of the Internet in the 1990s, the information extraction developed into Web information extraction, the high-profile project was the Web Excavation Project of Carnegie Mellon University "Center for Automated Learning and Discovery"; American Stanford University developed the extraction tool of extracting semi-structured information from Web[2]. Now the Web information extraction technology has developed into the automatic phase. But the rub is: due to the poor adaptability of the extraction rules, the accuracy rate of the extracted data will become lower as the automation degree becomes higher. As a result, the practicability of the technology is poor.

The earliest domestic documentation that involved in Web information extraction system research was *Semantic Tracing Analysis Algorithm in Information Extraction*[3], published in Apr. 2001. The latest documentation was *Web Information Extraction Based on Mutual Information Metric*[4], published in Dec. 2013, in the article the author presented the Web information extraction method which was on the basis of mutual information measure, could identify the noise information automatically and keep the key information. This method analyzes web pages by making them into DOM trees, and calculates the mutual information values of the leaf nodes. Then it gathers the leaf nodes block by block according to the DOM tree structure, and acquires recursive upwardly the mutual information value of tag <body> as the threshold value to distinguish noise and non-noise. Yang Shaohua, etal, of the Chinese Academy of Sciences presented the new method of generating the data template firstly, then automatically extracting the data from the web page by the detected

template; Institute of Artificial Intelligence, Zhejiang University proposed the Web information extraction which was on the basis of ontology[5], etc..

After checking the documentation we knew that no matter at home or abroad there were less researches which really involved the applications of ceramic products in the researches of Web information extraction system, and this article conducts the research on Web extraction of the ceramic products' information in the Business Website.

Technical Route of Web Extraction of Ceramic Products' Information

A. Determination of Web Extraction Model of Ceramic Products' Information

The structures of internet and its websites are diversify, standards are different, and the sites' scripting codes have no uniform layout, so you can not directly adopt the X path to locate node and extract information. The design idea of this article is to use the advantages of structured XHTML, by introducing the PHP open-source database SimpleDOM to carry out the HTML page analysis, the DOM tree is formed. And according to the specific rules of DOM tree on different websites, the products information on the web pages and page turning linkages can be analysed, realizing the extraction of related information from the Web page document. All the results that are extracted in accordance with the inquired conditions are all saved in the founded database of websiteextraction. Therefore, the Web extraction model of ceramic products' information which is established in this article is showed in Figure 1:

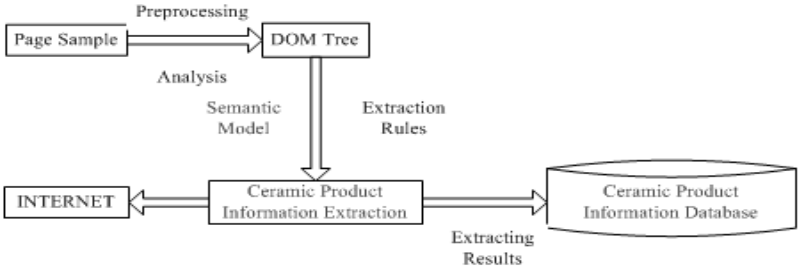

Fig.1 Web Extraction Model of Ceramic Products' Information

B. Preprocessing of Web Document

Most of the data on the Web is described by HTML, the HTML mingles data content and pattern of manifestation, which is adverse to the extraction, therefore to carry out the preprocessing of Web document, the treating process is generally subdivided into three steps: first transfer the HTML document into XHTML document; then analyze the XHTML into DOM tree; finally filter the DOM tree by the method of matching, to get rid of the irrelevant nodes and its content in the DOM tree.

C. Determine the Extraction Rules of Products' Information

To form the extraction rules of products' information in accordance with websites, for example, the rules of website http://www.ccmall.cn/ are as the following:

A. Find the first table with the ID of TableList on the web page

B. Loop gain the first table cell of tr on each line in the table

a) [Product's Picture Linkage]: the SRC property of the first IMG Tag

b) [Product's Name]: the first linking characters with A tag in the DIV classified as "namelist"

c) [Linkage of Product's Detail]: the first href linkage with A tag in the DIV classified as "namelist"

d) [Product Manufacturer]: the characters after "Shop Name" in the DIV classified as "namelist"

e) [Release Date]: the characters after "Release Date" in the DIV classified as "namelist"

f) [Place of Origin]: the inner characters of the DIV classified as "namelist"

g) [Price]: the inner characters of the SPAN classified as "price"

To build the matching web site extraction database, to determine the information extraction process, to retrieve data model mapping library, and make use of the website corresponding data model mapping rules, and to lead the information in the XML document into websiteextraction database.

Concrete Realization of Web Extraction of Ceramic Products' Information

A. Database Design

To build web site extraction database by using the development tool of Eclipse PDT, and the result is showed in Figure 2:

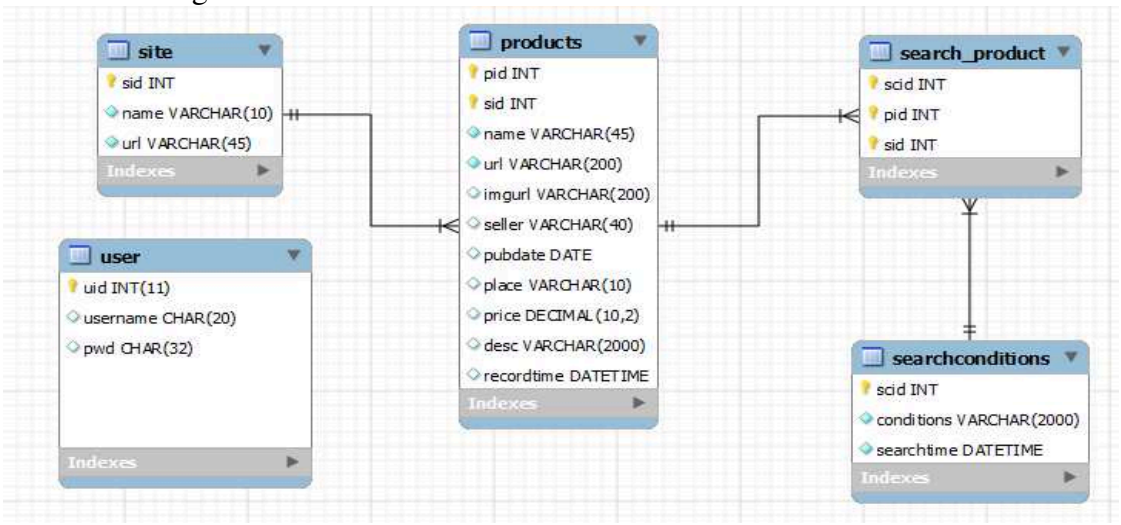

Fig.2 WebSiteExtraction Database

Site: Site information table, which is used for saving the basic information which is extracted by the web page from the site.

Products: Product information table, which is used for saving the products' information which is extracted by the web page.

Search_product: Extraction results' relationship table, which is used for saving extraction conditions and products' interacted system.

Searchconditions: Extraction condition table, which is used for saving extraction conditions.

B. Web Information Extraction

This system mainly through constructs five functional modules to realize the entire system functions, respectively are: Login function module(index.php), Information Extraction function module(search.php), Display module of extraction results(result.php), class of SiteProductSearch and class of MyDb.

a) Login function module(index.php): this module is mainly used to realize the function of login and register.

b) Information Extraction function module(search.php): this module is mainly used to input information extraction conditions, for example, to classify the ceramic in accordance with its usage, which can be classified into domestic ceramics, art (display) ceramics, sanitary ceramics, building ceramics, electrical ceramics, chemical ceramics, textile ceramics, etc.. Then we could extract according to customers' requirements. Part of the functional codes on web extraction of ceramic products information as the following:

```
function genSearchParams ($queryArr){      $sps = array();
  if(array_key_exists('querytext', $queryArr)){
        $sps[] = new SearchParam('NAME',$queryArr['querytext']);        }
  if(array_key_exists('price1', $queryArr) || array_key_exists('price2', $queryArr)){
        $p1 = array_key_exists('price1', $queryArr) ? $queryArr['price1'] : '';
        $p2 = array_key_exists('price2', $queryArr) ? $queryArr['price2'] : '';
        $sps[] = new SearchParam('PRICE',array($p1,$p2));      }
  return $sps;    }
```

c) Display module of extraction results(result.php): this module is used to display the products' information extraction results, and supports the EXCEL export function. How to display the products' information which is acquired in accordance with the inquiry conditions is also the important content of the extraction system. For example, the above EXCEL figure, which we get

according to the condition of “Bone China”, is classified by site, product, price, picture linkage, product linkage, release date, manufacturer, place of origin, and introduction.As is showed in Figure3, Figure 4:

d) Class of SiteProductSearch: this class is extracted in accordance with each site’s corresponding condition, and to analyze the products’ information from the results’ web page.

e) Class of MyDb: this class is to realize the read and write function of the database. Part of the functional codes are as the following:

```
private function connectDb(){          $dsn = array(       'phptype'    => 'mysql',
  'username' => $this->dbUser,        'password' => $this->dbPassword,
  'hostspec' => $this->dbHost,        'database' => $this->dbName,
            'new_link' => true         );
        $res = DB::connect($dsn);
        if(PEAR::isError($this->pearDbObj)){      $this->throwException($res);     }
          else{    $this->pearDbObj = $res;      }
```

Summary

With the high-speed development of information, ceramic products’ information has played a more and more important role in the development of ceramic enterprises, this article provides a new thinking for acquiring the ceramic products’ information, however it is far from enough, we shall excavate the customer’s needs in depth, to develop more reasonable and applicable Web information extraction system which is on the basis of ceramics’ E-commerce websites, strengthen the access to and the sorting out of the ceramic products information, standardize the information resources, and provide decision-making basis for ceramic enterprises to make product development strategy.

Acknowledgment

The research leading to these results has received the support of science and technology project of Jiangxi province education department "The application of Web information extraction technology in the ceramic e-commerce" (NO.GJJ13623) and Humanities and Social Science Research Project in Colleges and Universities of Jiangxi Province “Network group events countermeasure research based on web mining”(NO.JC1221） and Scientific Research Project of Jingdezhen Ceramic Institute “Text information filtering system based on Web”.

Keywords: fully homomorphic encryption;approximate GCD;sparse subset sum problem;public key size

Abstract. This paper puts forward a more efficient fully homomorphic encryption scheme with a view to improving the oversized public key based on the Dijk's scheme.Encrypted with a cubic form in the public key elements instead of quadratic form by adopting Gentry's fully homomorphic techonology.The results show that the public key size reduce from $\widetilde{O}(\lambda^7)$ to $\widetilde{O}(\lambda^6)$ compared to the Coron's scheme.The security of the proposed scheme is based on both the approximate GCD problem and the sparse-subset sum problem.

Introduction

Homomorphic encryption is also called privacy homomorphism.The notion was suggested by Rivest,Adleman and Dertouzos[1] back in 1978 which allows computation on encryption data without decryption.Although these relevant papers to this field had been put forward continuously in the later 30 years,there had been no breakthroughs[2-6].In 2009,Gentry described the first encryption scheme[7],which based on the fully homomorphic encryption scheme over ideals,making the fully homomorphic encryption come true in theory using of ideals[8].In 2010,Dijk,Gentry,Halevi and Vaikuntanathan made an improvement based on the fully homomorphic encryption over ideals and proposed a scheme over integers which could achieve fully homomorphic encryption without using of ideals,that is,fully homomorphic encryption over integers[8].Moreover,there were continuous many improved papers later[9-12].In 2011, Coron put forward a scheme of having shorter public key size[13] ,which reduced the public key size from $\widetilde{O}(\lambda^{10})$ to $\widetilde{O}(\lambda^7)$ by encrypting with a quadratic form in the public key elements,instead of a linear form.The idea consisted in storing only a smaller subset of the public key and then generating the full public key on the fly by combining the elements in the small subset multiplicatively.This paper reduces the public key size by encrypting with a cubic form in the public key elements and the result shows that the public key size is compressed from $\widetilde{O}(\lambda^7)$ to $\widetilde{O}(\lambda^6)$.

Preliminaries

1.1 Basic Notation

For a real number z ,we denote by $\lceil z \rceil, \lfloor z \rfloor, \lfloor z \rceil$ the rounding of a up,down,or to the nearest integer.Namely,these are the unique integers in the half open intervals $[z, z+1), (z-1, z]$ and $\left(z-\frac{1}{2}, z+\frac{1}{2} \right]$,respectively.For a real number z and an integer p ,we use $q_p(z)$ and $r_p(z)$ to denote the quotient and remainder of z with respect to p ,namely $q_p(z)=\lfloor z \rceil$, $r_p(z)=z-q_p(z)\cdot p$.

In this paper we usually denote parameters by Greek letters.Specificlly, we give some descriptions about the parameters:

λ : the security parameters of this scheme
γ :the bit-length of the integers in the public key
η :the bit-length of the secret key
ρ : the bit-length of the noise
τ :the number of integers in the public key
ρ' :the bit-length of the second noise

1.2 Related Definitions

Definition 1(Approximate GCD).Given a random set of integers S=$\{x_0, x_1, ..., x_n\}$,every x_i is close to the big prime number p and p is the most closed common factor of these integers.The problem of finding the most closed common factor p is the Approximate GCD.

Definition 2 (Sparse Subset Sum Problem(SSSP)).Given a set of integers S=$\{a_1, a_2, ..., a_n\}$and a integer x,whether exit a none-empty subset H$\in$ S satisfy that the sum of all elements in H is equal to x.The problem is called SSSP.

Definition 3 (Homomorphic Encryption Scheme). A homomorphic encryption (denoted by ε)is composed of the following four algorithms:

KeyGen:According to the security parameter λ,generate pk and sk of the scheme.

Enc:Given a plaintext $m \in \{0,1\}^*$,encrypt plaintext m with pk and get ciphertext c.

Dec:Input sk and c and run Dec,output m.

Evaluate:Input pk , circuit C having t inputs（be composed of addition gate and multiplication mod 2） and a string of ciphertexts **c**= $(c_1, c_2, ..., c_t)$ (c_i is the encryption of plaintext m_i),output $c^* = Evaluate(pk, C, c)$,

moreover,satisfy $Dec(sk, c^*) = C(m_1, m_2, ...m_i)$.

Definition 4 (Fully Homomorphic Encryption Scheme)If a scheme satisfy the contidition that the result of decrypting after arbitrary conputation on encrypted data is equal to the outcome of the same computation on plain data,the scheme is called fully homomophic encryption scheme.

Definition 5 (Augmented Decryption Circuits).Define following two augmented decryption circuits:

Dec-Add:Input sk and two ciphertexts c_1、c_2 and compute Dec（sk, c_1）+Dec（sk, c_2）mod2.

Dec-Mult: Input sk and two ciphertexts c_1、c_2 and compute Dec（sk, c_1）× Dec（sk, c_2）mod2.

We denote by $D_\varepsilon = \{$ Dec - Add, Dec - Mult$\}$the set of the two kind of circuits.

Definition 6 (Bootstrappable Encryption).Let $\varepsilon = (KeyGen, Encrypt, Decrypt, Evaluate)$ be a homomorphic encryption scheme,and for every value of the security parameter λ let $C_\varepsilon(\lambda)$ be a set of circuits with respect to which ε is correct.We say that ε is bootstrappable if $D_\varepsilon(\lambda) \subseteq C_\varepsilon(\lambda)$holds for every λ.

1.3 Gentry's ideological frame of fully homomorphic encryption scheme.

(1)Construct a somewhat homomorphic encryption scheme,which can evaluate a limited computations of polynomial.

(2)Control noise using the technology of ciphertext refresh.

(3)Squash the Decryption Circuit.

(4)get the fully homomorphic encryption scheme.

Coron's scheme with shorter public keys

2.1 Constructing ideas

Coron and Mandal proposed a fully homomorphic encryption scheme with shorter public keys with a view to improving the oversized public key based on the Dijk's scheme. The improved scheme reduced the public key size from $\tilde{O}(\lambda^{10})$ to $\tilde{O}(\lambda^7)$ by encrypting with a quadratic form in the public key elements,instead of a linear form.,

2.2 concret algorithm

KeyGen (1^λ)**.**Genenrate a random prime $p \in \left[2^{\eta-1}, 2^\eta\right)$.Let $x_0 = q_0 \cdot p$ where q_0 is a random square free 2^λ-rough integer in $\left[0, 2^\gamma / p\right)$.Generate integers $x_{i,b}$ for $1 \le i \le \beta$ and $b \in \{0,1\}$:

$$x_{i,b} = p \cdot q_{i,b} + r_{i,b}, 1 \le i \le \beta, 0 \le b \le 1$$

Where $q_{i,b}$ are random integers in $[0, q_0)$ and $r_{i,b}$ are integers in $\left(-2^\rho, 2^\rho\right)$.Let sk^*=p and pk^* = $(x_0, x_{1,0}, x_{1,1}, ..., x_{\beta,0}, x_{\beta,1})$.

Encrypt $(pk, m \in \{0,1\})$**.**Generate a random vector **b**=$\left(b_{i,j}\right)$ of size $\tau = \beta^2$ and with components in $\left[0, 2^\alpha\right)$.Genenrate a random integer r in $\left(-2^{\rho'}, 2^{\rho'}\right)$.Output the ciphertext:

$$c^* = m + 2r + 2\sum_{1 \le i,j \le \beta} b_{ij} \cdot x_{i,0} \cdot x_{j,1} \bmod x_0$$

Evaluate $(pk, C, c_1, c_2, ..., c_t)$**:**Given the (binary) circuit C_ε with t inputs,and t ciphertexts c_i,apply the (integer) addition and multiplication gates of C_ε to the ciphertexts,performing all the operations over the integers,and return the resulting integer.In addition,ciphertexts are reduced modulo x_0 after addition and multiplication.

Decrypt (sk, c)**:** Output $m \leftarrow (c \bmod p) \bmod 2$.

The scheme of this paper

In this paper,we reduced the public key size to $\widetilde{O}(\lambda^6)$ by encrypting with a cubic form in the public key elements.

3.1 Somewhat homomorphic encryption scheme

Our technique consists in working with integers $x'_{i,j,k}$ of the form $x'_{i,j,k} = x_{i,0} \cdot x_{j,1} \cdot x_{k,2}$ mod x_0 for $1 \le i, j, k \le \beta$.Then only 3β integers $x_{i,b}$ need to be stored in the public key in order to generate the $\tau = \beta^3$ integers $x'_{i,j,k}$ used for encryption.The public key size from τ down to $3\sqrt[3]{\tau}$ of γ bits.

We set the constrains on the scheme as follows:

$$\gamma = \omega(\eta^2 \log \lambda)$$
$$\eta \ge (3\rho + \alpha) \cdot \Theta(\lambda \log^2 \lambda)$$
$$\rho = \omega(\log \lambda)$$
$$\rho' = 3\rho + \alpha + \omega(\log\lambda)$$
$$\alpha\beta^3 \ge \gamma + \omega(\log \lambda)$$

keygen (1^λ). Genenrate a random prime $p \in \left[2^{\eta-1}, 2^\eta\right)$.Let $x_0 = q_0 \cdot p$ where q_0 is a random square free 2^λ-rough integer in $\left[0, 2^\gamma / p\right)$.Generate integers $x_{i,b}$ for $1 \le i \le \beta$ and $b \in \{0,1,2\}$:

$$x_{i,b} = p \cdot q_{i,b} + r_{i,b}, 1 \le i \le \beta, 0 \le b \le 2$$

Where $q_{i,b}$ are random integers in $[0, q_0)$ and $r_{i,b}$ are integers in $\left(-2^\rho, 2^\rho\right)$.Let sk =p and pk = $(x_0, x_{1,0}, x_{1,1}, x_{1,2}, ..., x_{\beta,0}, x_{\beta,1}, x_{\beta,2})$.

encrypt $(pk, m \in \{0,1\})$**.**Generate a random vector b=$(b_{i,j,k})$ of size $\tau = \beta^3$ and with components in $\left[0, 2^\alpha\right)$.Genenrate a random integer r in $\left(-2^{\rho'}, 2^{\rho'}\right)$.Output the ciphertext:

$$c = m + 2r + 2\sum_{1 \le i,j,k \le \beta} b_{i,j,k} \cdot x_{i,0} \cdot x_{j,1} \cdot x_{k,2} \bmod x_0$$

evaluate and decrypt: same as in the Coron's scheme.

3.2 Correctness

Permitted Circuits （C_ε）: the definition is same as the literature[13].

According the encryption algorithm of the scheme in this paper,we know:

Exit an integer k,make $c = m + 2r + 2\sum_{1\le i,j,k\le\beta} b_{i,j,k}\cdot x_{i,0}\cdot x_{j,1}\cdot x_{k,2} + k\cdot x_0, |k| \le \tau$

Because $x_{i,b} = p\cdot q_{i,b} + r_{i,b}, x_0 = q_0\cdot p$,we can derive

$$c = m + 2r + 2\sum_{1\le i,j,k\le\beta} b_{i,j,k}\cdot r_{i,0}\cdot r_{j,1}\cdot r_{k,2} \bmod p$$

This gives using $\rho' \ge 3\cdot\rho + \alpha$:

$$|c \bmod p| \le 2^{\rho'+1} + 2\tau\cdot 2^{3\rho+\alpha} \le \tau\cdot 2^{\rho'+2} \quad (1)$$

Let $C \in C_\varepsilon$ be a permitted circuit with t inputs and let C' be the corresponding circuit oprating over the integers rather than modulo 2.Let $c_i \leftarrow Encrypt(pk, m_i)$ .We have :

$$c \bmod p = C'(c_1,...,c_t) \bmod p = C'(c_1 \bmod p,...,c_t \bmod p) \bmod p \quad (2)$$

From (1) and the definition of permitted circuits,we obtain:

$$|C'(c_1 \bmod p,...,c_t \bmod p)| \le 2^{\eta-4} \le p/8$$

Therefore $C'(c_1 \bmod p,...,c_t \bmod p) \bmod p = C'(c_1 \bmod p,...,c_t \bmod p)$,which implies from (2): $c \bmod p = C'(c_1 \bmod p,...,c_t \bmod p)$

and eventually:

$$(c \bmod p) \bmod 2 = （ C'(c_1 \bmod p,...,c_t \bmod p) \bmod 2 = [C'([c_1 \bmod p]_2,...,[c_t \bmod p]_2)]_2$$

So, $[c \bmod p]_2 = C(m_1,...,m_t)$,that is,the scheme is correct.

3.3 Making the Scheme Fully Homomorphic

In this paper,we still adopt the techonology of SSSP like [4] to compress the decryption circuit and finally get the fully homomorphic encryption scheme,because the large complexity in computing $\lfloor c/p \rceil$ of decryption algorithm.

Concrete algorithm is as follows:

keygen（1^λ）.Call the sk=p and pk=（$x_0, x_{1,0}, x_{1,1}, x_{1,2},..., x_{\beta,0}, x_{\beta,1}, x_{\beta,2}$）,which is generated in above-mentioned somewhat homomorphic scheme.Let M= $\lfloor 2^\kappa / p \rceil$ .Choose a random number $q_0 \in [0, 2^\gamma / p)$,and let $x_0 = q_0\cdot p$ .Generate integers $x_{i,b}$:

$$x_{i,b} = p\cdot q_{i,b} + r_{i,b}, 1 \le i \le \beta, 0 \le b \le 2$$

Where $q_{i,b}$ are random integers in $[0.q_0)$ and $r_{i,b}$ are integers in $(-2^\rho, 2^\rho)$.Let $pk^* = (x_0, x_{1,0}, x_{1,1}, x_{1,2},..., x_{\beta,0}, x_{\beta,1}, x_{\beta,2})$.

Additionally generate random bit vectors $s^{(0)}$, $s^{(1)}$ and $s^{(2)}$ of length $\lceil \sqrt[3]{\Theta} \rceil$,subject to the conditions that $s_1^{(0)} = s_1^{(1)} = s_1^{(2)} = 1$, $\mathbf{S} = \{(i,j,k) : s_i^{(0)}\cdot s_j^{(1)}\cdot s_k^{(2)} = 1\}$.

Initialize a system-wide pseudo-random number generator f with a random seed **se**,and use $f(se)$ to generate integers $u_{i,j,k} \in [0, 2^{\kappa+1})$ for $1 \le i,j,k \le \sqrt[3]{\Theta}$, $(i,j,k) \ne (1,1,1)$ .Then,set $u_{1,1,1}$ such that

$$\sum_{(i,j,k)\in S} u_{i,j,k} = M \bmod 2^{\kappa+1}$$

Where $M \leftarrow (z_{i,j,k})$.

Compute encryption $\sigma^{(b)}$ of the vectors $s^{(b)}$,by picking,for each $i \in \left[1, \lceil \sqrt[3]{\Theta} \rceil\right]$ and $b = 0,1,2$,random integers $r'_{i,b} \in (-2^\rho, 2^\rho), q'_{i,b} \in [0, q_0)$,and setting:

$\sigma_i^{(b)} = s_i^{(b)} + 2r'_{i,b} + p \cdot q'_{i,b} \bmod x_0$

Finally,output the secret key as sk= （ $s^{(0)}$, $s^{(1)}$, $s^{(2)}$ ） and the public key as pk=$\left(pk^*, se, u_{1,1,1}, \sigma^{(0)}, \sigma^{(1)}, \sigma^{(2)}\right)$.

encrypt （ *pk,* $m \in \{0,1\}$ ） *and evaluate* **:** Choose a random integer matrix $b=\left(b_{i,j,k}\right)1 \le i,j,k \le \beta \in \left[0, 2^{\alpha}\right)^{\beta\times\beta\times\beta}$ and a random integer r in $\left(-2^{\rho'}, 2^{\rho'}\right)$.Output the ciphertext: $c^* = m + 2r + 2\sum_{1\le i,j,k\le\beta} b_{ijk} \cdot x_{i,0} \cdot x_{j,1} \cdot x_{k,2} \bmod x_0$

Let $y_{i,j,k} = u_{i,j,k} / 2^{\kappa}$ and $z_{i,j,k} = \left[c^* \cdot y_{i,j,k}\right]_2$ .For every $z_{i,j,k}$,keeping only $n = \lceil \log_2(\theta+1) \rceil$ bits of precision after the binary point.Define the matrix z= $\left(z_{i,j,k}\right)$ .Output the expanded ciphertext c= （c^*,z）.

decrypt（*sk,* c^* ,*z*）**:**Output $m \leftarrow \left[c^* - \lfloor \sum_{i,j,k} s_i^{(0)} \cdot s_j^{(1)} \cdot s_k^{(2)} z_{i,j,k} \rceil\right]_2$.

Comparision of public key size in several schemes

The fully homomorphic encryption scheme in this paper is proposed based on Dijk's scheme and Coron's scheme with a view to improving the oversized public key,so we compare the public key size in the three schemes.The result is shown in Table 1.

Table1

Scheme	Based the assumption of hard problem	Public key size
Dijk's scheme	GCD and SSSP	λ^{10}
Coron's scheme	GCD and SSSP	λ^{7}
The scheme in this paper	GCD and SSSP	λ^{6}

Conclusion

The scheme in this paper is proposed based on Dijk's scheme and Coron's scheme,constructing fully homomotphism by adopting Gentry's fully homomorphic idea frame.Reduce the public key size by encrypting with a cubic form in the public key elements and the security also depends on GCD and SSSP.Comparing to the first two scheme,the scheme in this paper have shorter public key size and higher computing efficiency.

Design and implement an application development platform based on open source technology

TIEBIN LIU

University of Chinese Academy of Sciences, China Futures Association

liutiebin@cfachina.org

Keywords: open source; J2EE; application development platform.

Abstract. This paper design and implement a J2EE application development platform based on open source technology by studying on Paoding-Rose, Spring, Mybatis, Activiti and other open source technologies. The platform can improve enterprise capabilities of independent research and development IT system.

Background

It is necessary to build enterprise independent R & D capacity , and the reasons are listed below: 1) we need a unified IT architecture and management of enterprise application development; 2)improve the response speed of business requirements; 3) ensure information system security and stability; 4)protect existing IT investment; 5)reduce the developer's skill requirements and employee turnover risk. This article based on depth study on open source technology platform which domestic mainstream software vendors and large financial institutions use. We use Paoding-Rose, Spring, Mybatis, Activiti and other open source technologies to design and implement a set of J2EE-based application development platform. This platform comply with software lifecycle management specification and business-centric. This platform also combine business processes and provide the major functions required for enterprise application R & D system.

Introduction to the relevant open source technology

The platform mainly use the Spring Framework and Paoding-Rose, combined with MyBatis persistence mapping technology,， Activiti workflow technology and other open source technology as the core design. This section briefly Introduce related technologies.

2.1 Paoding-Rose Development Framework

Paoding-Rose Development Framework (hereinafter referred to as the Rose) is released by Renren website and Sticky website. It's a Java web development framework based on open source Spring specification and Servlet specification[1]. This development framework has the following advantages[2]:

1．Convention over configuration: package path, class name and class method name do not require declaration in configuration file, as long as the name contains specific keywords and Annotation keywords. As long as this condition is satisfied, the other naming parts can easily be modified and do not require to modify any configuration .

2．Automatic Binding: This is a very useful feature. In Struts2, we need to use struts2 tags and "set" to automatically bind form data. But Rose doesn't. It has no label restrictions, free to binding properties, and pass parameters directly through "Annotation" without "set" data. The data persistence layer of Jade Framework also provide automatic binding properties. It does not require any set or get methods, so it's greatly enhance the development efficiency.

3．REST style: As the development of Rose is based on Spring, so it use a lot of Spring MVC components. It also brings the Spring MVC REST style for Rose. It has a lot of advantages of Spring MVC. Rose optimizes the URL mapping and page-value operations of Spring MVC, so it's more elegant and full support for REST.

4. Minimalist Jade: Jade framework greatly enhance the efficiency of development. DAO interface method plus an SQL statement can implement database operation and assignment.

5. Portal Technology: This is one of the original JAVA background technology created by architects of Renren website. The basic principles to implement this technology is module segmentation of page which requires a lot of data for rendering it (such as public home page). Each module as a "Window" access data from concurrent database, and then re-integrate data, and ultimately presented to the user. Back office operations similar SCALA concurrent algorithms that block the data and concurrent computing. Foreground effect is similar with page fragment loading technique that SINA Weibo used. In order to ensure that the user's response speed, the first part of the page is loaded clip, and gradually display the entire page. Facebook also have a similar solution.

6. Compatibility: Rose use filters instead of intercepting the request by Servlet. Currently, most of the framework intercept requests by filter. The benefit is that you can easily be compatible with other frameworks. Based on this point, Rose has REST style and coexist with Struts which intercept requests based on Servlet, so we can reform legacy systems.

2.2 MyBatis framework

MyBatis framework collects multiple concepts and methods of operational relations data. It's a powerful data access tool and solution[3]. It's an excellent persistence framework which supports the common SQL queries, stored procedures and advanced mapping. MyBatis framework mainly consists of two categories: DAO components and SQL Map components. The common tools include Log management, etc. Its structure is shown in Figure 2-1.

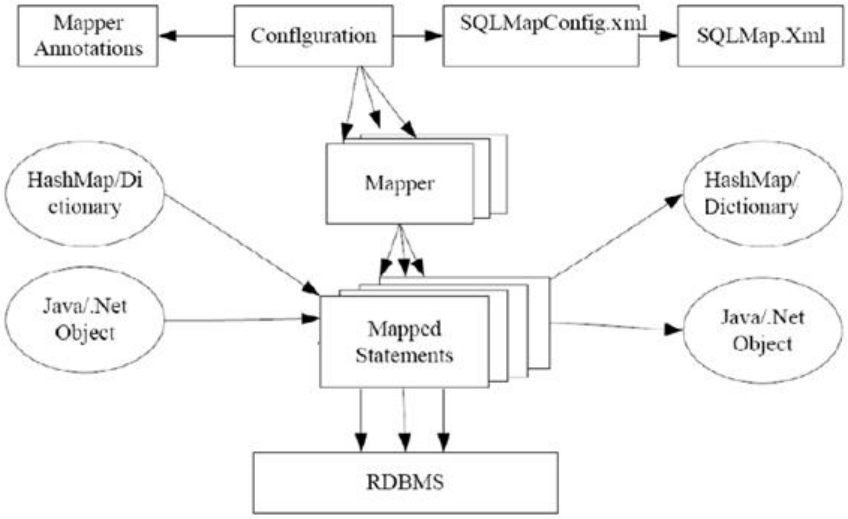

Figure 2-1 MyBatis component architecture diagram

Since MyBatis supports developer write SQL statements, so developers can flexibly use SQL statements to query different objects. But Hibernate framework has no ability to do that. Also MyBatis performance is much higher than ORM framework. Those are main reasons why a lot of developers choose MyBatis currently [4].

2.3 Activiti technology

Activiti technology is from the JBoss jBPM4 project which is dedicated to collaborative management among business people, developers and system managers . Activiti is an open source lightweight workflow and BPM platform product [5] and the latest version of Activiti is 5.8. Activiti is a scalable workflow management system, using an intuitive process language to describe business processes. Activiti abstracts part of the business process or factors into tasks, wait states of asynchronous communication, timers, automatic operation, etc. These operations are bundled together by Activiti, so Activiti has a powerful and easy control flow mechanisms which can be configured in any database or can be deployed on any application server [6].

Analysis and design of the application development platform

3.1 Requirements Analysis

As a development platform, it must provide technically efficient , easy , reusable, monitoring and manageable development platform for enterprise IT R&D staff. The purpose of the development platform is to improve the abilities of enterprise IT project management and independent R&D capabilities. Its functional requirements include providing design and development tools, run-time environment and management monitoring tools. Design and development tools are mainly based on eclipse visual mode which integrate design, development, assembly, testing, maintenance, deployment, management in one integrated development environment. Also it provides guided business object development, visualization, process and report design, rapid deployment capabilities. The development platform have run-time environment which are provided by J2EE container, workflow engine, reporting engine, basic services and other core modules, etc. These modules provide the necessary running environment for applications and services. To facilitate system debugging for R&D staff and run-time monitoring for maintenance staff, the development platform should provide graphical management and monitoring capabilities.

From the perspective of good performance and advanced technology, its non-functional requirements include: a modular platform architecture, loosely coupled and high performance design; based on J2EE standards, easy to use, easy to build efficient development system, improve application development efficiency.

3.2 Functional Design

Demand for self-development requirements, the development platform functional design include:

1. Code Generator: Using Eclipse plug-in, building the code, graphical reporting tools and other features, developers can set up service and entity to meet the business requirements through visual way, and automatically generates all files (including configuration files, JAVA code and SQL scripts) from the page to the persistence layer.

2. Support System: a complete object-oriented support system which provides buffer management, workflow engine, etc. and a large number of API for JAVA code and JS. In order to ensure the platform itself scalability, stability and flexibility, the platform should provide maximum abstraction whether its on the page presentation, or on any layer in CURD.

3. Component Services: Provides a set of component-based services, including organizational management, rights management, menu management, application configuration management, page assembly and other functions.

3.3 Architecture Design

Technical architecture of the development platform fully consider modularity, low coupling , high performance requirements of hierarchical design, and its provide a hierarchical bottom-up support for the system. To reduce the complexity of system integration and application deployment, the base layer use packaging technology to shield storage, computing, transfer and other technical details. Based on above mentioned, the development platform clearly defines a common service layer, application layer and the business component layer, and provide application software development life-cycle management capabilities, shown in Figure 3-1.

3.4 Security Design

Security is an essential part of the development platform. Good security design can protect applications and data security and ensure stable running of the system. So we should fully consider the problems and prevent it from system data layer, application layer, network layer, and maintenance, etc.

From application security aspect, development platform is designed to use dedicated login control module which provides identity and authentication features for access control. Its use the MD5 encryption algorithm[7] to provide the user password encryption feature, and use combination of two or more identification techniques to achieve user authentication. Its use encryption technology to ensure security of data transmission and verification. The application platform use the targeted improvement and configuration middleware to allow the server provide stronger enforcement of access control based on the user's identity, security and policy. In order to prevent cross-site scripting

and SQL injection attacks, the development platform filter and background process the data which are submitted by the users.

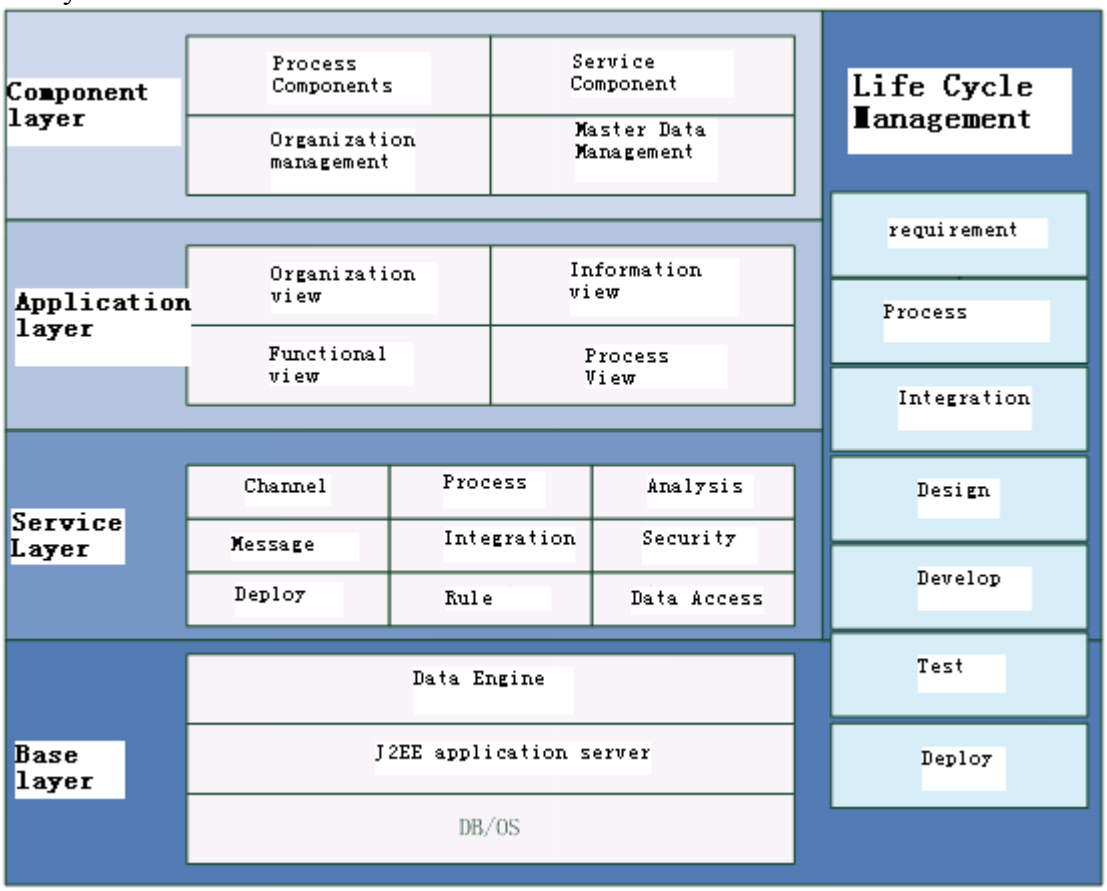

Figure 3-1 System architecture of the development platform

Implement the application development platfrom

4.1 Selection of open source technology Experiment design

To ensure openness of the application development platform, we determine use mainstream mature open source frameworks and development tools in terms of platform technical realization.

After integration testing, we determine use JDK1.6 as the basic framework of JAVA development compiler environment, use Servlet-2.5 as the intermediate layer, use Spring-3.0.3 as JAVA development framework, use MyBatis-3.0.6 as persistence layer, and use Paoding-Rose as Java Web development framework.

Java Web development tool use Eclipse Java EE IDE for Web Developers, use Indigo Service Release 2 as the communications infrastructure components, use PL / SQL as the database programming tools, and use Tomcat as Web-based server.

4.2 Implement the architecture of application development platform

The application development platform is based on J2EE, Eclipse and other open source technology. Its use mainstream MVC design framework and its functions cover design, development, testing, deployment, operation , monitoring and other aspects. Entire technology architecture consists of three layers: the data access layer, business logic and page presentation layer.

1. Data Access Layer

It use Mybatis framework, use SQL statements to access the database and SQL statements can be easily be optimized. It can also implement Mybatis-based database cache.

2. business logic layer

(1) use Paoding-Rose (Lightweight J2EE Framework) which is based on open source Spring and use "convention than configuration" principle, almost zero-configuration, enable developers to quickly develop the background service.

(2) use Spring's transaction management

(3) use standards-based open source Activiti Spring framework which supports BPMN2.0 processes as the workflow engine.

(4) use birt [8] which can be integrated with Paoding-Rose as reporting engine.

3. Page presentation layer

Using JSON format data exchange with back system, we can diversify front display mode and use different styles or different topics foreground template engine on display. It also supports both desktop and PAD terminal adapter to facilitate the development of mobile Internet applications.

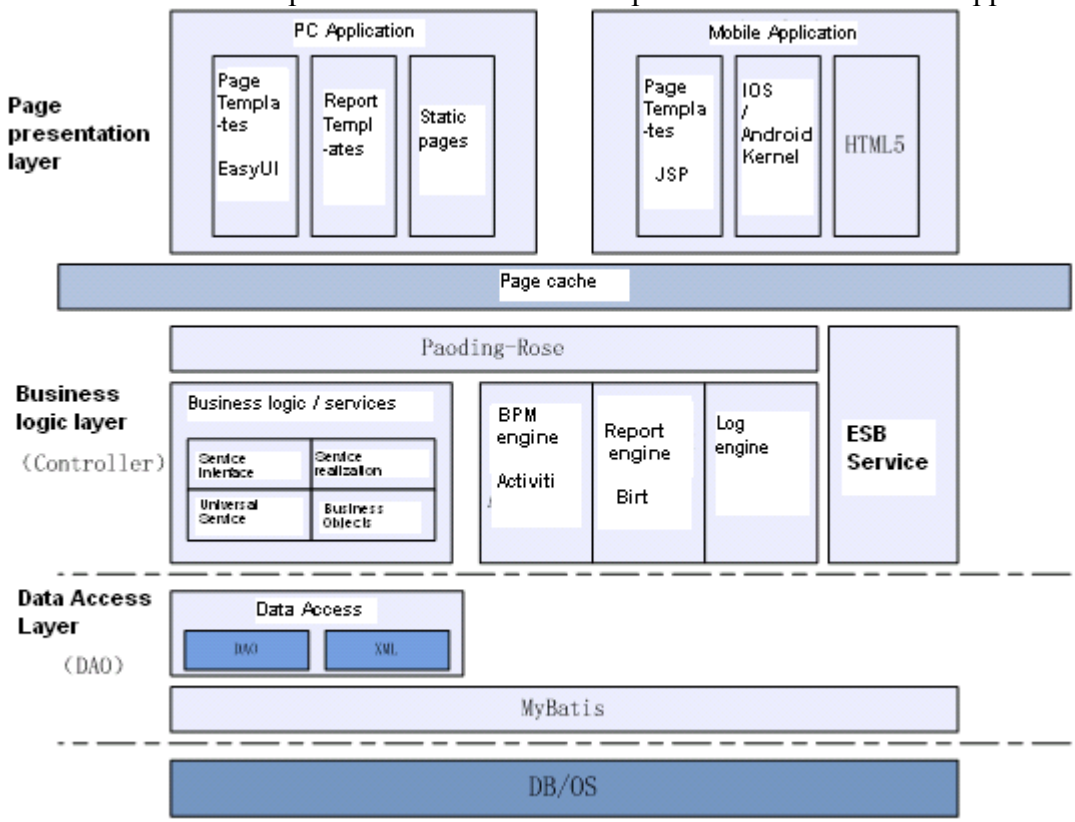

Figure 4-1 The Application Development Platform Architecture

4.3 Implement the critical functions of application development platform

4.3.1 Modular Rapid Development

According to the certain rules interconnection， application development platform use the standard interface and other same subsystems to compose more complex systems. Public modules and core modules which abstract from the system functions form the platform API. It reduces the complexity of application and makes the applications simplification and standardization in design, testing and maintenance operations.

4.3.2 Business Process Management

Application development platform uses BPMN2.0 business process definition model to achieve business process lifecycle management, including design modeling business processes, testing and debugging, deployment, operation, monitoring and management. This function consists of routing which is responsible for parsing the definition of business processes and coordinate activities, orchestration engine which process client requests, visual business process modeling designers and process management monitoring module which based on the Eclipse plug-in technology.

4.3.3 Access Management

Based on security design model, the development platform use role-based access control (RBAC) model. It establishes a set of access management functions including user management, role management, organization management, data rights , functions management, menu management, etc.

4.3.4 PAD terminal adapter

With the rapid development of mobile Internet, the application development platform achieve the PAD terminal application development capability. By defining a unified front end data transmission

protocol, it realizes server side sharing between mobile devices and PC, so as to achieve cross-platform, cross-terminal synchronous project development.

4.3.5 One-click deployment

The application development platform design a solution for one-click rapid deployment. It intergates software compiler , test step, deploy step, etc. to an automated tool. One-click rapid deployment use pure JAVA language and generate XML schema documents which can be integrated into the development environment by given template, with good cross-platform and convenience.

4.3.6 Old module rapid death mode

For previous problems that internal application can not quickly offline outdated or useless business function modules, the application development platform introduces the concept of "old module rapid death". By sufficiently reduce coupling of modules, the application development platform achieve the old module simple, fast and no risk peeling, so that internal applications can be maintained in spite of application increasingly large and complex .

Summary

Using open source technology to build the application development platform can provide openness, flexibility, autonomy and other advantages. On the basis of this foundation form a set of development operating system , and it can support from concept, development, maintenance of IT products R&D process. The application development platform can effectively enhance the enterprise IT R&D capabilities.

Keywords: network, network management, switching nodes, node server;

Abstract. Where in a metropolitan area server controls the network management process and the service process of a node switch and a node server under it, while the node server controls the network management process and the service process of an access switch and a terminal under it. Where in the metropolitan area server or the node server allocates an address to each network device by sending a query packet to each communication port, and establishes a clear network topology on the main control server side during the allocation process, in a main control mode. Thus, during the transmission process of a specific data packet, the main control server (metropolitan area server or node server) directly allocates a corresponding communication link (because it clearly knows the device topology of the whole network), without the need of carrying out route negotiation between each network device, thus a stable transmission rate may be guaranteed, and delay may be avoided.

Introduction

The current network technicians seem to miss a basic theory: the root of network packet loss phenomenon is flow non-uniformity. Macroscopically, when the sending speed is high in one time period, it is certain to cause jam in another time period; no upper limit can be given to the peak flow of the network so long as the network flow is non-uniform, and any arbitrary large bandwidth may be occupied in a short time[1].

At preset, device manufacturers recommend ultra-wideband access networks of tens or even hundreds of Megabit to each household. However, even if optical fiber enters each household, it is difficult to exhibit a video communication service with good QoS to the consumers. In spite of what complex QoS measures are taken, the transmission quality of IP Internet can only be "improved", and no quality of network transmission can be "guaranteed"[2].

The Network Access Process of a Metropolitan Area Network

The Network Access Process of a Metropolitan Area Server and a Node Switch, a Node Server

Firstly, each switch that is allowed to access the network must be registered on a server, the registration information of an switch includes the device type and device identification of the switch, and an switch that is not registered will be unable to access the network.

As shown in FIG. 1:

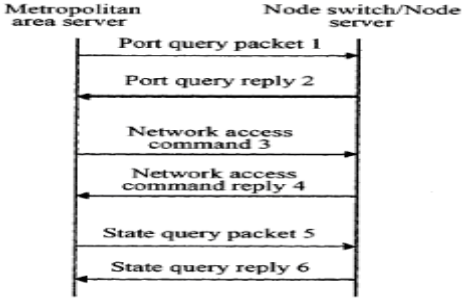

FIG. 1 A node server

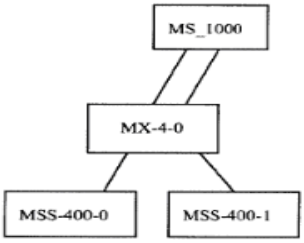

FIG. 2 Schematic diagram

1). a server sends a query packet to each port, after a switch receives the query packet, it sends a reply (the reply contains the device type and device identification of the switch, which is the intrinsic information of each switch);

2). after the server receives the reply issued by the switch, it knows that the current port is connected with a switch, then it finds the switch information in an internal registration information table of the server, and sends a network access command to the switch (informing the metropolitan area network address and label of the switch), and after the switch receives the network access command, it accesses the network and sends a network access command reply to the server at the same time;

3). after the server receives the network access command reply issued by the switch, it knows that the switch has accessed the network, and then a state query packet is sent to the port each second to check whether the switch works normally; and at the same, a port query packet is sent to other ports of the switch to check whether other devices are connected under the switch. If the switch works normally, after it receives the state query packet, it will sends a state query reply to the server. When the server does not receive a state query reply in a certain period of time (for example, in 6 seconds), it will be considered that the switch has been removed from the network, and no state query packet will be sent any longer; instead, it continues to send a query packet to the current port[3,4].

An Example of Network Access Interaction Between a Metropolitan Area Server and a Node Switch, a Node Server

All devices on the metropolitan area network are described with a device information table, and a device may be uniquely identified by a device type of 2 bytes and a device identification of 6 bytes; generally, it will be described according to that different device types have different device information tables, for example, node switch information table and node server information table. The items of a device information table are consisted as follows:

1) device identification: 6 bytes, which is written into a hard disk or flash of a metropolitan area server when a device is registered, and imported to the CPU memory after the metropolitan area server is powered on;

2) device state: 2 bytes, wherein 0x0000 represents that the device does not access the network, and 0x0001 represents that the device is to be accessed to the network (the metropolitan area server issues a network access command packet, but no network access command reply is received), 0x0002 represents that the device has accessed the network (set by the metropolitan area server after receiving a network access reply packet);

3) device address: 2 bytes, the metropolitan area network address allocated to the device.

The metropolitan area network address has a length of 16 bits, all devices on the metropolitan area network have a unique access network address (including metropolitan area server, node switch and node server). A table with a size of the sixteenth power of two, i.e., 64K, is maintained by a CPU module of the metropolitan area server, which is called metropolitan area address information table, and each item of the table is consisted as follows:

Similarly, a metropolitan area query label describes the connection from a metropolitan area server to a node switch or a node server, while a metropolitan area reply label describes the connection from a node switch or a node server to a metropolitan area server. In order to simplify the design, it is hypothesized that the two has a one-to-one correspondence, for example, if the metropolitan area query label from the metropolitan area server to a node switch is 0x0008, the metropolitan area reply label from the node switch to the metropolitan area server is also 0x0008; moreover, OUT label equals to IN label. Thus, another table with a size of the sixteenth power of two, i.e., 64K, is maintained by a CPU module of the metropolitan area server, which is called metropolitan area protocol label information table, and each item of the table is consisted as follows:

1) label occupation descriptor: 2 bytes, wherein 0x0000 represents that this label is not used, 0x0001 represents that this label is standby (the metropolitan area server issues a port query packet

by this label, but no network access reply packet is received), and 0x0002 represents that this label is used (set by the metropolitan area server after receiving a network access reply packet);

2) label descriptor: 2 bytes, the metropolitan area network address of a device corresponding the label;

3) label route description information: 4 bytes, for describing the metropolitan area network address and port number of the previous-hop switch of the metropolitan area query label packet, wherein the first 2 bytes represents the metropolitan area network address of the previous-hop switch, and the last 2 bytes represents the port number of the previous-hop switch.

Network Interactive Process Instance

As shown in FIG. 2 for example, it is hypothesized that the metropolitan area server has four 1000M fiber interfaces and one CPU module interface. If the four 1000M fiber interfaces are in turn defined as port 0 to port 3 and the CPU module interface is defined as port 4, the type of the metropolitan area server will be MS-1000, and port 0 and port 1 of MS-1000 are respectively connected with port 2 and port 3 of MX-4-0, and port 0 of MX-4-0 is connected with MSS-400-0, and port 1 of MSS-400-0 is connected with MSS-400-1.

The network access interaction process is as follows

1) After server MS-1000 is powered on, it initializes the hardware and imports a configuration file from the hard disk to the CPU memory (for example, the registration information of a node switch and the registration information of a node server, etc.), server MS-1000 initializes the metropolitan area address information table and the metropolitan area protocol label information table, and all the items are cleared (which represents that all addresses and labels are not used), and server MS-1000 configures its own metropolitan area network address as 0x0000, that is, item 0x0000 of the metropolitan area address information table is configured as follows:

address occupation descriptor: 0x0002 represents that the address is used;

device descriptor: 0x0000 represents metropolitan area server;

device resource description information: the metropolitan area server has four 1000M fiber interfaces, which are in turn defined as port 0 to port 3, and the CPU module interface is defined as port 4, the type of this node server is MS-1000, the metropolitan area network address of a device connected to a network port thereof is not allocated, and downlink flow count of each of its network ports is 0;

The next available address is 0x0001, and the next metropolitan area protocol label is 0x0000;

Server MS-1000 initializes tables 4, 5, 6 and 7

configuring table 4 as "0 0000 0000 0000 0000 0000" to "0 0000 1111 1111 1111 1111", i.e., the transmission of all metropolitan area query label packets is shut down;

configuring table 5 as "1 0000 0000 0000 0000 0000" to "1 0000 1111 1111 1111 1111", i.e., all metropolitan area reply label packets are oriented to the CPU;

configuring tables 6 and 7 as "0 0000 0000 0000 0000 0000", i.e., the transmission of all unicast or multicast data packets is closed;

Port 2 of switch MX-4-0 receives a query packet with a metropolitan area protocol label of 0x0000 according to the topological graph, then:

configuring table 5 "101 0000 0000 0000 0000"=>"0 0100 0000 0000 0000 0000", i.e., a reply packet with a metropolitan area protocol label of 0x0000 is oriented to port 2;

Port 3 of switch MX-4-0 receives a query packet with a metropolitan area protocol label of 0x0001 according to the topological graph, then:

configuring table 5 "101 0000 0000 0000 0001"=>"0 1000 0000 0000 0000 0000", i.e., a reply packet with a metropolitan area protocol label of 0x0001 is oriented to port 3;

Two reply packets (which contains the device type and device identification of the current switch and the port number that receives the query packet) are sent, wherein the header of one packet is 0x0900 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000, and at the same time, it marks in the packet that the port number receiving the query packet is port 2;

The header of the other packet is 0x0900 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0001, and at the same time, it marks in the packet that the port number receiving the query packet is port 3;

After port 0 of server MS-1000 receives a query reply packet with a metropolitan area protocol label of 0x0000,

1) according to the device type in the reply packet, server MS-1000 knows that it is a node switch, and compares the device identification in the reply packet with the device identification items in the device information table on the node switch one by one, until a totally identical item is found, this indicates that the device has been registered, and it finds that the device state item is 0x0000, so it knows that the device does not access the network;

2) it checks item 0x0000 of the metropolitan area protocol label information table according to the metropolitan area protocol label 0x0000 in the reply packet, and knows that the previous-hop switch is server MS-1000 (with an address of 0x0000), and the port number is port 0;

3) according to field number 5 in the reply packet PDU (which indicates the switch port number that receives the query packet), server MS-1000 knows that port 0 is connected with port 2 of an switch.

A network access command is sent (informing that the metropolitan area network address of the switch is 0x0001), the head of the packet is 0x9000 0x0000 0x0001 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000 0x0000;

Conclusion

As can be seen from the above description, the node server can know flow information of its port, so can report itself flow information in the metropolitan area network, and then respective node switches and metropolitan area server can know the flow information of its port because the flow information of respective ports may be simply added. Because the floe information of each port can be known, so when the metropolitan area server set metropolitan area network communication link, the metropolitan area server can perform control according to flow information to achieve path control and transmission effect well

The application research of Lightweight J2EE security framework

An Ming Hu

Tianhe College of Guangdong Polytechnical Normal University GuangZhou 510540

E-mail:anminghu@hotmail.com

Key words: Spring Security;Information Security;Access Authorization

Abstract. Lightweight J2EE framework to actually use efficiency, has been widely used in all kinds of information system development,However ,Spring is open source framework, its security and access control has been problem of concern,How to construct safe and effective Web applications, is the development process of the important link must be thinking。Based on the Spring frame structure technology on the basis of summing up the access authorization control methods and strategies, highlights the Spring framework in the development process of the advantage technology.

Introduction

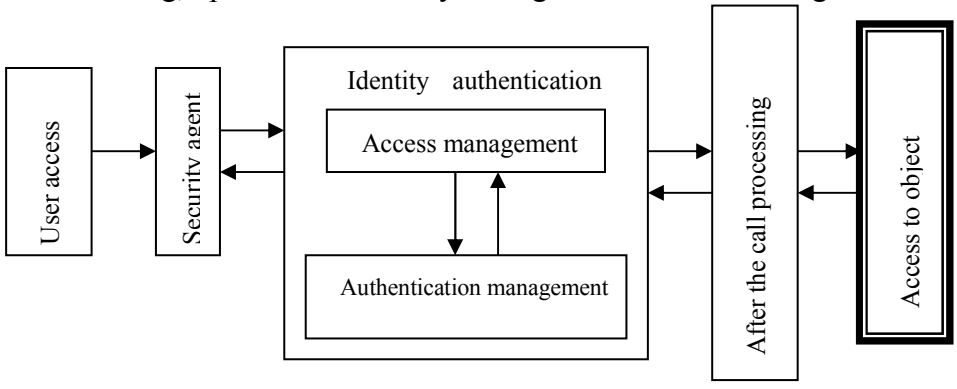
In the framework of SSH information system software development process, effective control of access to resources, has always been an important part of the development process. How to build a secure, efficient Web applications, developers must consider the problem.

At present the mainstream development technology, the access control model, is usually divided into two parts to realize, namely, user authentication and user authorization. User authentication, which verify the identity of the user information in the system is legal; user authorization, verify that users have to perform the operation of power.

In the early days, Spring Acegi frameworks usually used in the development of Spring, the Spring Acegi framework while powerful, But it is not based on the AOP thought development, And Spring Acegi applications in a large number of the filter, the filter needs maintenance chain, complex configuration. While the new version of the Spring Security framework, based on AOP technology, have complete access control capacity increases at the same time a series of new function, For example: a simplified configuration, inheritance OpenID; support single sign on; support Aspectj pointcut expression language etc.. The development efficiency makes the Spring Security framework has a higher and broader application of space.

The Realization Of The Spring Security Framework

Spring Security framework mainly contains: authentication management, access control security agent, decision-making, operation of identity management and call management etc..



.

Fig.1 Spring Security Framework Access Process

Spring Security framework configuration consists of 2 parts, storing the user account information database and Web.XML file, applicationContext-security.xml file configuration.

1) to realize user authentication database

User authentication database contains 2 database table, user table and user permissions list. One user table is used to record the user name and password, password using MD5 encryption; user permissions table is used to record the user of the role, is used to configure the limit user access; The table structure as shown in Table 1, shown in table 2.

Table 1. The user information table

The field name	Type	Explain
UserName	Varchar(20)	User name
Password	Varchar(15)	password;
Enable	Boolean	user mode

Table 2. The table of user role

The field name	Type	Explain
UserName	Varchar(20)	User name
authority	Varchar(15)	authority

The simulation data are as follows:

```
+-----------+---------------+
| username  | authority     |
+-----------+---------------+
| admin     | ROLE_ADMIN    |
| manager   | ROLE_MANAGER  |
| user      | ROLE_USER     |
+-----------+---------------+
3 rows in set (0.00 sec)

mysql> select * from users;
+-----------+----------------------------------+----------+
| username  | password                         | enabled  |
+-----------+----------------------------------+----------+
| admin     | 21232f297a57a5a743894a0e4a801fc3 |        1 |
| manager   | 21232f297a57a5a743894a0e4a801fc3 |        1 |
| user      | 21232f297a57a5a743894a0e4a801fc3 |        1 |
+-----------+----------------------------------+----------+
```

2）The Web.XML file, applicationContext-security.xml file configuration

The Web.Xml file configuration consists of 2 points, the standard 1Spring frame start listener, 2 on the Spring Security framework to achieve Spring filter SpringSecurityFilter AOP startup configuration. Configuration list as follows:

Spring framework listener code list:

```
<context-param>
        <param-name>contextConfigLocation</param-name>
        <param-value>classpath:applicationContext*.xml</param-value>
    </context-param>
```

SpringSecurityFilter class configuration：

```
<filter>
        <filter-name>springSecurityFilterChain</filter-name>
        <filter-class>
            org.springframework.web.filter.DelegatingFilterProxy
        </filter-class> </filter> <filter-mapping>
        <filter-name>springSecurityFilterChain</filter-name>
        <url-pattern>/*</url-pattern>
<!—According to the needs for access control can be set here to filter -->
    </filter-mapping>
```

DelegatingFilterProxy is a Spring class, the configuration is designed for Spring Security boot provides a guide, to implement filtering using SpringBean through the proxy class form.

applicationContext-security.xml configure.

applicationContext-security.xml, The file is Spring important Securit file, for each resource configuration Web site access, configuration code list is as follows.

<http auto-config="true" access-denied-page="/accessDenied.jsp">
<intercept-url pattern="/AdminManager" access="ROLE_ADMIN" />
<intercept-url pattern="/UserManager" access="ROLE_USER" />
<form-login login-page="/login.jsp" authentication-failure-url="/login.jsp?error=true" default-target-url="/index.jsp" />
<anonymous/.><http-basic/><logout/></http>
The validator configuration:
<jdbc-user-service data-source-ref= " dataSource "
users-by-username-query= " SELECT u. UserName,u.Password,u.enabled FROM users u where u.username=? "
authorities-by-username-query= " SELECT u.username,a.authority
FROM users u JOIN authorities a ON u.username=a.username WHERE U.username=? " /></authentication-provider>

In the applicationContext-security.xml file, the access control under the HTTP node for each allocation site, For example, assume that there are two directory sites AdminManager and UserManager were assigned to the ROLE_ADMIN and ROLE_USER permissions user access, while the system login page and image resources is to allow anonymous access, then filter configuration none without permission check.

The above code list there are two points to note: the specified login failed to access the page access-denied-page properties for the HTTP node, the access to the page must enable anonymous access.The <form-login/> node is used to specify the login page, by default Spring Security framework will be easy to generate a login page, it is recommended to design the login page.

To design the login page should pay attention to submit form form action address is j_spring_security_check, list the code as follows:

```
<form action="${pageContext.request.contextPath}
/j_spring_security_check" method="post">
      User name:<input type="text" name="j_username"></input><br/>
    The code:<input type="password" name="j_password"></input><br/>
        <input type="submit" value=" Sign in"></input>
</form>
```

Spring Security tag library

Spring Security framework JSP tag libraries according to the user's permissions to control the display of some part of the page and hide, such as a ERP system, management interface can distinguish between the interface and the group manager department general manager interface through the label.

Spring Security framework tag library contains 3 tabs, which are authorize, authentication and accesscontrollist.

Authorize tag: used to determine if contains the content should be displayed

Authentication tag:Used to obtain the current certification object content.

Accesscontrollist tag: to protect the content based on access control lists.

Controls whether the content should be displayed. The attribute domainObject the label represents the domain object, and the hasPermission property to check permissions, so as to achieve a deeper level of protection object.

Method of use are as follows.

The first in the JSP page into <% @ taglib prefix= "sec" uri= "http://www.springframework.org/security/tags"%>

Security/tags "% >

In the JSP page in the application for example:

```
 <sec:authorize ifAllGranted="ROLE_ADMIN">
<a href="admin.jsp"> Enter the admin.jsp page
```

```
! </a><br/> <hr/>      <a href="DocumentServlet?method=add"> New documents
 </a><br /></sec:authorize>
```

Conclusion

In this paper, user authentication, access control on the Spring Security framework application configuration method of authorization and commonly used functions were discussed.

The Spring Security framework provides a complete and practical Web authorization and access control model, the URL access control, can control access to the Web application system resources, can meet the development needs of the majority of application system.

The Solution of P-Teredo Service Traversing Symmetric NAT

Fuyang Xia

Wuxi Professional College of Science and Technology, Wuxi, China

email: xfy016@126.com

Keywords: Teredo; P-Teredo; IPv6; NAT; success rate

Abstract. P-Teredo is a service that enables IPv4 nodes behind of the symmetric NAT to acquire the IPv6 connection by the arithmetic of port prediction and tunnel technology. The theory of Teredo service and classes of NAT was introduced in this paper. It describes the structure of P-Teredo service and the method of acquiring the client's address which applies the algorithm of port prediction. Some methods which can improve the success rate of port prediction were proposed. Finally, the success rate of network connectivity and the analysis of performance were given.

Preface

IPv6 as the core technology of the next generation internet provides nearly infinite address space which improved the security and data integrity, with automatic address configuration, mobile computing and data multicast, etc., the application of IPv6 provides more efficient service quality. But IPv6 couldn't replace IPV4 in the short time. IPv4 and IPv6 networks coexist in the application. Now, NAT has been used to solve those problems of public IP address lack and network security, so how to make IPV4 nodes behind of NAT communicate with IPV6 nodes has become the focus of research. Teredo service has realized the IPv4 nodes behind of NAT communicating with IPv6 nodes by encapsulating IPv6 data packets in the UDP packets of IPv4.But Teredo service can not traverse Symmetric NAT, because the client host transmits packets to different address will be mapped into different address and port, so its problem of traversing NAT is very difficult. Aiming at the problem, the prediction algorithm based on Teredo (P-Teredo) service has been used to traverse Symmetric NAT, then the IPv4 node behind of Symmetric NAT to acquire the network connection of IPv6 easily.

Teredo service

Teredo is a service which can make IPv4 node behind of NAT to acquire the network connection of IPv6.Teredo service has the Teredo client, Teredo server and Teredo repeater. The Teredo client can access the IPv4 network by sending a Teredo service request to the Teredo server to acquire IPv6 network access. The Teredo server can access the IPv4 network through the global routing address and it provides IPv6 connections for the Teredo client. Teredo repeater locates between Teredo client and IPv6 network; it performs data processing and data forwarding through the Teredo service.

The operation rules of Teredo service: firstly, the Teredo client generates an IPv6 request packet, then encapsulates it in an IPv4 UDP packet, and then sends the packet to Teredo server through the IPv4 network. When the server received the router request packet of IPv6, it will send the response packet the client, the response packet includes a prefix and the public IP address and port number which are mapped by the Teredo client through the NAT. The Teredo client generates its own IPv6 address according to the response packet, and uses the address to communicate with IPv6 node. The IPv6 address format is shown in Figure 1.

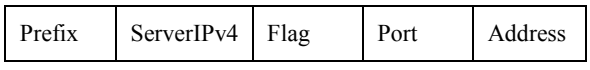

Fig.1 The format of IPv6 address

Prefix: 32bit address of Teredo service; Server IPv4: IPv4 address of Teredo server; Flag：16bit address and NAT device type; Port: UDP port of client; Address：IPv4 address of client.

NAT Device Type

(1) Full cone NAT: All requests from the same internal IP address and port are mapped to the same external IP address and port. And any external host can send a message to the internal host by sending a message to the mapping external address.

(2) Restricted NAT: All requests from the same internal IP address and port are mapped to the same external IP address and port. But unlike the former is that the external host sends back the packet to internal host when it has received the packet from the internal host.

(3) Port Restricted NAT: It is similar to restricted NAT. But an external host sends the packet to the internal host using external address X and port P on condition that the internal host has sent packet to the IP address X and port P.

(4) Symmetric NAT: The address from same internal IP address and port to different destination IP address and port will be mapped different external IP address and port. And the external host will send back UDP packet to internal host when it has received a packet.

Teredo service can traverse the former three type of NAT, but it can't traverse the Symmetric NAT, because the external address will be mapped to different port when the host sends the packet to different IP address and port in the Symmetric NAT. So the client host can't acquire the effective port information from the response information of Teredo server. This paper proposes a prediction algorithm of P-Teredo traversal NAT method based on Teredo for solving the problem of traversing Symmetric NAT.

The P-Teredo Service Based on Port Prediction

A. P-Teredo Architecture

The reason of Teredo service can not traverse the Symmetric NAT is that it can't predict the assigned IP address and port when the Teredo client will send data at the next time. The idea of P-Teredo is that the Teredo client acquires the enough prediction information by sending many times request to Teredo server. The service can predict the possible assigned port according to the information, so it will finish the traversing of Symmetric NAT. The system architecture of P-Teredo service is shown in figure 2.

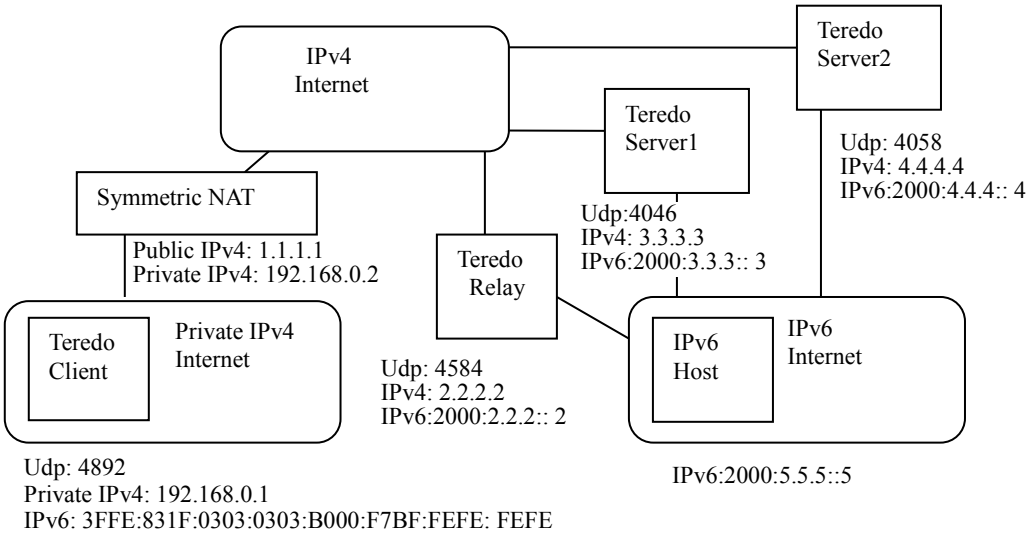

Fig. 2 Module structure of TCP protocol

The mapping port of Teredo client in NAT is changing because the Teredo client is in Symmetric NAT, so you must know the port allocation strategy for NAT if the Teredo client will communicate with the external network host. The Teredo client is located in the Symmetric NAT as shown in figure 2.There are two Teredo server, including Teredo Server1 and Teredo Server2,in the system. The two servers are used for returning the corresponding response message when the Teredo client send routing request message to them. Teredo relay is to realize the function of packet

forwarding. Teredo relay encapsulates the IPv6 data packets from Teredo host into IPv4 UDP data packets, and then sends these packets in IPv4 network. Contrarily, Teredo relay unpacks the IPv6 data packets from the IPv4 data packets of the Teredo client, and then sends them to IPv6 host.

B.Port Prediction algorithm

The linear growth port allocation strategy is used in the port of Symmetric NAT. The mapping ports in NAT exists the relationship of linear growth when the same IP address in Symmetric NAT sends data to different destination address. The port prediction algorithm by using the P-Teredo service traversing the Symmetric NAT is described as follows.

(a)Teredo client sends the request message to Teredo server1 and Teredo server2 respectively. The mapping external addresses of Teredo client are 1.1.1.1：4096 and 1.1.1.1：4098 from the two times response message.

(b)According to the acquired two ports, the port assigned spacing could be calculated as ΔP=4098-4096＝2.

(c)When Teredo client connects the network, the prediction assigned port is P=Pl+ΔP=4098+2 =4100(including P1 is the last mapping port).

(d)Teredo client acquires the mapping IP address in NAT according to the response message from Teredo server1.Teredo prefix of 32 bits is 0x3FFE:831F, Teredo server IPv4 address of 32bits is 0x03030303,flag of 16 bits is 0xB000,external port of 16 bits is 4100 xor 0xFFFF=0xF7BF, external address of 32 bits is 0x01010101 xor 0xFFFFFFFF =0xFEFEFEFE .The IPv6 address of Teredo client is 3FFE:831F:0303:0303:B000:F7BF:FEFE:FEFE.

(e)Teredo client sends the connection request message to IPv6 host according to the IPv6 address. The IP address is 2000:5.5.5::5.Then the IPv6 host sends the responding response message to Teredo client for confirmation connection.

C．Improve Success Rate of Port Prediction

There is problem about critical time period and port distribution in the port allocation strategy based on prediction. The critical time is from the client sends the connection request message to the client sends the connection request packets to the destination host. Application A1 and application A2 are the two applications which run in the Symmetric NAT. First, A1 respectively sends the request message to the two Teredo servers at t0 time. Then the external mapping address and the spacing of port distribution of Teredo client could be acquired according to the response message from server. The possible allocation port could be calculated in the process of data transmission by the mapping address. Then A2 sends a packet to the remote host at t1 time, the prediction port of A1 may be used when the packet goes through the NAT. Then there is error when A1 sends packet to the remote host at t2 time according to the recent prediction port, because the prediction port of A1 has been used by A2.So the correct prediction critical time period is timeΔt which is between t0 and t2.Therefore,in order to improve the accuracy of the prediction, the critical period of Δt should be minimized. The range of port allocation is that the Symmetric NAT allocates the port between a range such as oxa000~0xafff.These ports are the circular distribution. The reason of failure port prediction in P-Teredo service is the follows.

(a) There is another request occurs between the critical time period t0 and t2.

(b) The distribution port arrives at the bottom of port scope in the port restrict scheme.

(c) The use rate of UDP in the local network.

There are several improvement methods for the reason of failure port prediction.(a)Reduce the use rate of UDP. Minimize the number of applications in the Symmetric NAT.(b)Minimize the critical time period. Through optimizing the algorithm allows the t0 to T2 interval of time as short as possible, and to reduce the probability of the occurrence of another request in the critical period of time, so the accuracy of prediction of port should be improved.(c)Multi-port prediction strategy. To set a status table of port use information in NAT. The port use information could be found from the table when creating a new connection. The host should use the next prediction port if the port has been used and create the new IPv6 address according to the new port. Then the host sends the request to Teredo host to establish a connection between each other using the new IPv6 address, until the successful establishment of the network connection. The successful rate of network connection could be improved by multi-port prediction strategy.

Performance Analysis

To test the performance of this method in the practical application, we wrote a test program to test the method.The test of successful rate of network connection. The performance of port prediction algorithm has a great deal to do with the use frequency of UDP in client, so we tested the success rate of client network connection at different rate of UDP load. In the case of the low load (two applications), the medium load (six applications) and the high load (twenty applications), the network connections has been acquired using the prediction algorithm. Thirty times network connections were tested at each kind of load. The test results as shown in table I.

Table I. Network connections at each load

	Connections times	Successful times	Success rate %
Low load	30	30	100
Medium load	30	30	100
High load	30	27	92

The algorithm works well at the low load and the medium load, and the success rate of network connection is 100%.But the success rate of connection declines under the high load, because the increasing probability of new request occurs at the critical time period and the probability of hit port at one time declines. According to the prediction of the port to establish new client IPv6 address and port connection attempt, which increases the system cost, reduce the network connection success rate.

Prediction algorithm of P-Teredo service is a good solution to the problem of Teredo service cannot traverse Symmetric NAT, the prediction algorithm using multi-port, improve the success rate of the network connection, and make the Teredo service to use more widely. However, P-Teredo service exist some problems. It can traverse the NAT of UDP type and can not traverse the NAT of TCP type because it is based on Teredo service. In the algorithm we set the Symmetric NAT port assignment rule is a linear growth strategy. it has some limitations, because if the NAT port assignment rule is random distribution, it can not traverse the NAT. But the port allocation strategy in Symmetric NAT was linear in fact, so the algorithm is practical.

Conclusions

This paper presents the P-Teredo service used to traverse the Symmetric NAT, which realizes by the port prediction algorithm based on Teredo service. We should find the address mapping rules and build the network connection using IPv6 address according to the prediction port. Meanwhile the multi-port prediction strategy has been used to improve the hit rate of port prediction. So it can ensure the validity and high efficiency of the algorithm. P-Teredo service can traverse the symmetric NAT and acquire the high success rate of network connection. So it has high useful value in the future.

Keywords: Enterprise Application Integration, Web Service, CXF

Abstract. Communication between heterogeneous systems is difficult to be achieved without affecting the existing systems in Enterprise Application Integration. A kind of dynamic web services publishing software based on CXF is proposed in this paper. The purpose of this software are twofold. Firstly, it encapsulates specified data called by other systems into web service published dynamically which unifies customization among heterogeneous systems. Secondly, the function of service monitoring provided allows users to get the real-time information of published web services. The proposal software has been deployed in a Chinese large-scale military enterprise. Practice in the enterprise shows that the software can simplify web service development, quickly build a web service which encapsulates large amounts of data, and achieve information sharing within the enterprise environment.

Introduction

In the past few years, various information systems have been applied in a Chinese large-scale military enterprise. These information systems, such as Human Resource Management System, ERP, Financial System and Positional Titles Declaration System, have been developed by different techniques, programming languages, and databases. At the same time, one of the central activities in enterprise software development is the continuous process of integration of various technologically heterogeneous parts into an evolving system. EAI projects have a very high failure rate due not only to technological complexity, but because the systems being integrated are critically tied to the business process itself [1]. So the enterprise introduced an ESB model based on SOA infrastructure to meet the integration needs.

The key step for integration based on SOA in this enterprise is how to achieve effective communication between heterogeneous systems quickly and easily. Supporting the shift toward service-oriented development and SOA is Web services [2]. A dynamic web services publishing software solution based on Apache CXF is proposed in this paper. It minimizes heavy workload and accelerates application integration process. The encapsulation of specific application data will be in the form of Web Service, which can be called by other applications. In addition, the software also implements the management and monitoring to all services within domain.

Related Research

Enterprise Application Integration (EAI) is the process of integrating multiple applications that were independently developed, may use incompatible technology, and remain independently managed [3]. It improves competition by integrating the heterogeneous systems according to business requirement. Service Oriented Architecture (SOA) is the best way to utilize existing IT systems to meet new challenges.

SOA is a solution for designing and setting up the loosing coupling software system, it can publish business functions in the manner of programmable and accessible services, and the other application can use these services by using the published and findable interface [4]. SOA can use Web Services to allow standards-based applications to interact over the Internet. This enables machine-to-machine

communication, speeding the application-interaction process and eliminating the need for human intervention [5]. Enterprise Service Bus (ESB) is one mode of SOA infrastructure. ESB acts as the middleware glue infrastructure that holds SOA parts together and integrates and manages the communication between different Web Services, applications, and data sources [6].

Apache CXF is an open source services framework that makes web service development easy, simplified, and standard based. CXF provides many features such as fronted programming, support for different transports and data bindings, support for different protocols, and other advanced concepts like Features and Invokers [7]. More specifically, it has become the preferred in the domain of building Web Services using Java language.

Dynamic Web Services Publishing Software

Requirements analysis. Current information systems mostly use different databases to store data. If we can bypass the complicated business logic and define the encapsulation of Web Service data to database level directly, it will be possible to unify customization among different systems. This method may be implemented by extracting and encapsulating sharing data from original data. For example, staff basic information of Human Resource Management System which is developed in Delphi language is stored in the Mysql2000 database. In that case, using the original method to do Web Service development on the system is cumbersome. As we know, the use of Web Services as an infrastructure of service sharing has made it possible to provide collaboration and interoperability in distributed system [8]. We can acquire staff basic information and encapsulate it as web service, so that it can be called by other applications without changing Human Resources Management System. The target of this paper is to complete the operations by simple connection configuration to system database.

The original data encapsulation can solve the drawback that heterogeneous systems are difficult to be united. Once web service is configured by users, service engine will publish the service, and then other applications can invoke it with the addresses of web service at this point. For web service that has been published, the system provides query operation to find service by service address, name, description or other information. The system also provides the function of service monitoring, so that users can get the real-time information of published web services. In addition, users can use the system to test web service. Enter the requested values for each parameter, appropriate web service is invoked and the result will be returned for review. Meanwhile, the test cases also can be saved to achieve test cases management. Each test case is bound to the appropriate web service for multiple tests. Considering data security, the system should achieve full rights management, prevent data leaks and misuse occurs. System use case diagram is shown in Fig.1.

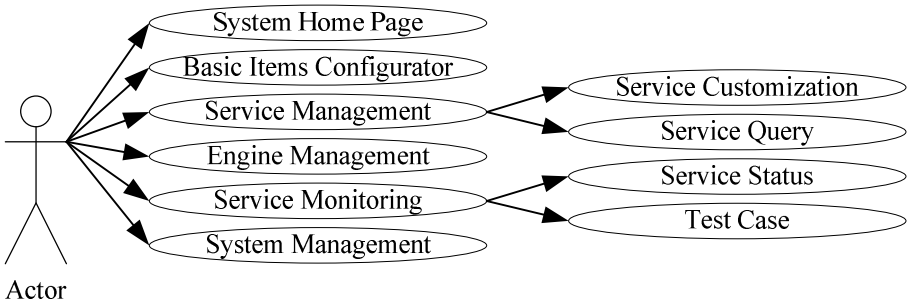

Fig.1 System Use Case Diagram

Software Architecture. The system is divided into three parts: foreground management, core database and background service engine. Foreground management maintains data in core database and queries service information stored in core database. Core database is a bridge between foreground and background, which stores basic information. Background is a service engine based on CXF, including service publication and customization, service monitoring. Background gets service information from core database to complete service creation and publication, thus other applications on the integration platform of enterprise applications can call the service. System architecture design is shown in Fig.2.

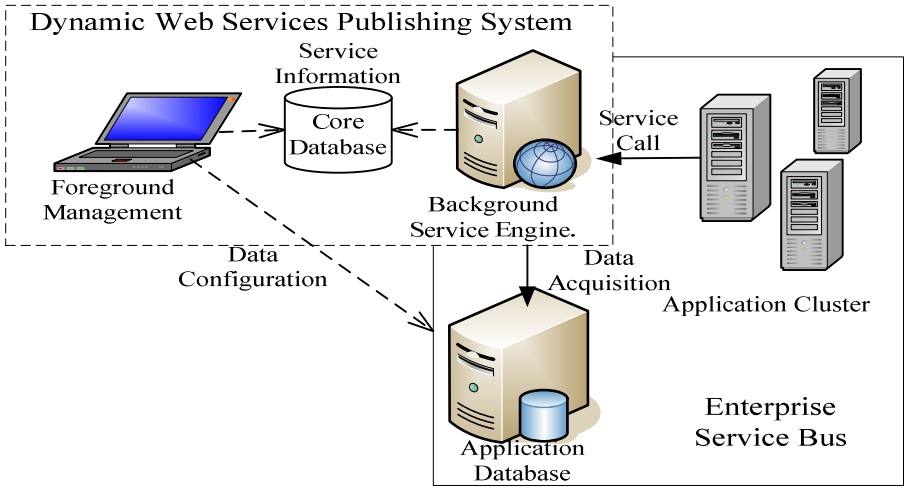

Fig.2 System architecture design

The integration of information systems can be regarded as data synchronization among databases. From this perspective, the software can also been seen as a data synchronization tool of databases [9]. The basic information of web service created and customized by foreground is stored in core database, and background service engine gets service information from database to complete service creation and publication. The server updates service information in real time for users to view from foreground.

According to the architecture and application background, MVC architecture is used. View is user interface which is mainly made up of Html elements; Model represents the business rules and business data, and can be reused by multiple views; Controller is responsible for receiving users' input and then calling appropriate models and views to complete the operation. The software is further extended on the base of MVC architecture that divides the whole system into 5 levels: data link layer, data encapsulation layer, controller layer, function layer, interface layer. It is relatively independent between the various layers. Upper layer achieves specific function by calling lower interface. The system overall structure is shown in Fig.3.

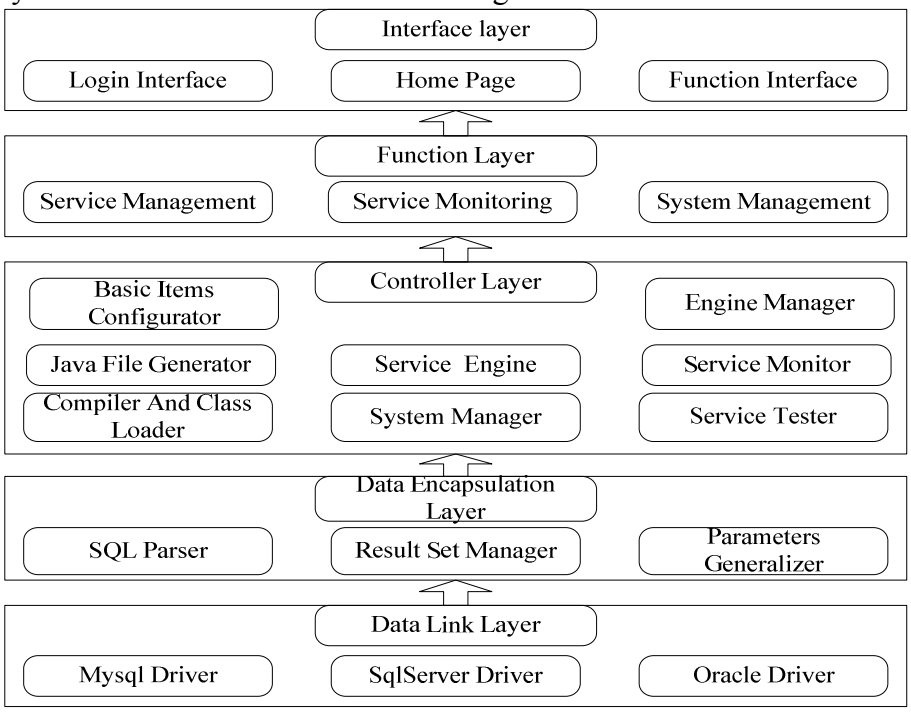

Fig.3 System overall structure

Data link layer uses Java simple factory design pattern, create corresponding database connection driver for database connection according to incoming database type parameter. Data encapsulation

layer uses standard J2EE design pattern - DAO pattern, including SQL parser, result set manager, parameters generalizer etc. SQL parser verifies and tests SQL query; result set manager can carry out advanced operations; parameters generalizer determines the parameter type according to the information of database table. Controller layer is divided into multiple functional components according to different business needs and composed of relatively independent processors, such as basic items configurator, Java file generator, engine manager, service monitor and so on. Function layer mainly achieves complex business logic and completes corresponding business processes through controller. Interface layer achieves complex business presentation and interactive support under different browsers. Each functional interface corresponds to an implementation class, such as service customization, service management, service monitoring, system configuration etc.

Design and Implement of Service Engine. Service engine is the background application based on CXF written in Java language. Service engine is the core of the system, including database connection pool, service management thread and service monitoring thread. Database connection pool supports Oracle, SqlServer, MySql and other types of databases; service management thread takes charge of service customization and publishing. Core technologies related include multiple threads, binary access, dynamic compilation and loading of Java file, etc. Service engine uses a structure that separates data link layer and logical layer to avoid compatibility problems caused by different database types. The layered architecture is shown in Fig.4.

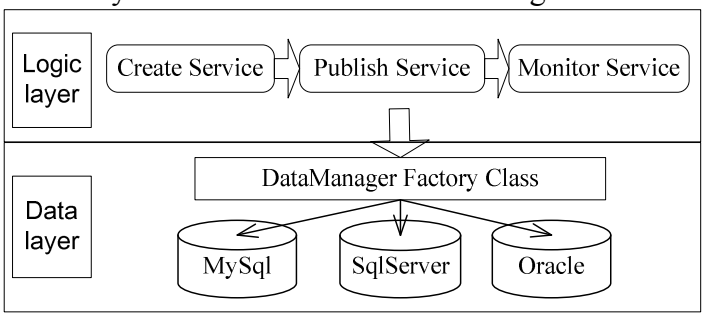

Fig.4 Service engine layered architecture

Data link layer is responsible for the interaction of different types of databases. This layer creates and returns appropriate database driver and connection on the basis of database type contained in service information.

Logic layer can be divided into two parts: Server and Monitor. Server is responsible for service creation and publishing while Monitor takes charge of service monitoring. Server thread notifies Monitor thread to start and monitor service after finishing the service creation.

Service creation is the first step, and also the most crucial step in building web service. After users finishing web service customization and configuration in foreground, information related to corresponding service is stored in the database including service name, address, port number, and parameter, and then service engine will acquire and publish the information to make it a real Web Service. In the implementation process of this system, Web Service is published based on JAX-WS standard.

Service class generated by compiler is stored in a specific directory after service creation. Next, URLClassLoader class loads the service class into main thread and generates corresponding instances. At this point, relevant service class and its instances have already existed in the thread, then use the CXF engine to publish them. After the successful service publishing, Server thread will be responsible for updating service address information in database.

Service monitoring is completed by a specialized thread. Main thread hangs and starts a specialized Monitor thread for monitoring service. Once all services have been created and published, Monitor thread will acquire all published service information and store it in memory first, then visit each service every certain time (60s) to get status information, and write it to corresponding database field to update service in real time at the end.

Software Deployment

Runtime environment. System runtime environment is composed of foreground manager runtime environment and background service engine runtime environment. Foreground database management system needs the support of JDK1.6, SqlServer and Tomcat server, and uses B/S architecture and Justep X5 studio development tool. Background service engine is also developed in Java language with Eclipse development tool. In addition, enterprise internal LAN and network environment of other heterogeneous systems running are still needed for the system to run.

Practice Situation. This system achieves the comprehensive management and maintenance of Web service in a large-scale military enterprise. It can be used by system developer, tester and maintainer as an assistant during the building of enterprise ESB. This system has been well-received in the commissioning phase.

Conclusions

This paper proposes a dynamic web services publishing software solution based on CXF in Enterprise Application Integration. The solution completes Web Services dynamic customization, management, testing, monitoring and other functions through the use of JAX-WS and provides a strong support in building the enterprise ESB information platform.

The innovation of this solution is that users are liberated out from traditional web service development pattern. Users have no need to pay much attention to different technical solutions of different systems. They focus on business level and finish web services customization and publishing just by simple service configuration which reduces much work.

Though this software plays an important role in the Web services management and monitoring, there are still some shortcomings and deficiencies, such as operation efficency. It will be upgraded and improved according to the concrete conditions in the future. So the system has better usability, efficiency and robustness, direction and difficult it is to continue to study.

The Design And Implementation Of Micro Player

Hui e Chen

Tianhe College of Guangdong Polytechnical Normal, University GuangZhou 510540

E-mail: yifanchenchen@163.com

Keywords: micro player;Function Realization

Abstract. Windows Media Player developed by Microsoft Player, it is a component of Microsoft Windows, can support through plug-ins enhancements. In this paper, by applying the ActiveX control, design a set play audio files, MIDI files and Windows Media files, movies (MPEG), such as video files as one of the players play a variety of Media files.

Introduction

Visual C++ 2010 can be used to create Windows platform Windows applications and network applications, is one of the most popular Windows platform application development environment, compared with the previous version, the new added several new features introduced in the C++11 standard support. "Reflect the diverse functions of micro player program is a comprehensive application of new features in Windows applications.

Ideas Of The Program Design

The website often give us free to download the player with the storm video, Mplayer player, Flash player, video, QQ, mainstream video formats are supported, most player software size there are dozens of MB- hundreds of MB, taking up a lot of resources, this paper optimized the player occupied resources and support video format based on the points of design, a mini player 160KB, resources, and through the creation of application program, application program interface design, application functions of three parts in-depth analysis of the implementation of the new function of micro player.

The Steps Of Program Design

1) To Create The Application Project

First create a dialog box MFC application based on micro player; the "file | new | project" menu, open the "new project" dialog box, select the project template for the "MFC application", and in the name of the project, add micro player to preserve the path, click "next"; in "MFC the application wizard" "application type" options "dialog based; in" the MFC Application Wizard "" advanced "options, select the" ActiveX control "to support ActiveX controls, and finally click" finish "button.

2) Application Program Interface Design

In the VS2010 integrated development environment, add Windows Media Player control to the application of the project, design of main program dialog box.

The first choice the "view", select the item micro player resources under the Dialog, double-click the dialog resource IDD_MICRO PLAYER_DLALOG, open the dialog box resource editor. From the "toolbox" the shortcut menu, select "options", will pop up "Choose Toolbox" dialogue ActiveX controls. Choose to add ActiveX controls from the "COM" list, click "OK", complete the ActiveX control to the toolbox, you can see the toolbox on a Windows Media Player control, and can be put to use the control as a standard control.

The second step is shown in the dialog box, select a name for the Windows Media Player ActiveX controls, click "OK" button, to complete the "toolbox" add "Windows Media Player" controls. As shown in the dialog box, select a name for the Windows Media Player ActiveX controls, click "OK" button, to complete the "toolbox" add "Windows Media Player" controls.

The third step is to add the Windows Media Player controls the menu resource. Open the "resource view", click the right mouse button on the Menu, select "add resources" in the pop-up menu, select Menu in the pop-up dialog box, click the "new" button, the Insert menu resource. Among them, the Popup attribute in the Menu to False, can change ID to ID_OPEN or ID_CLOSE.

Table 1. Add menu item attribute table

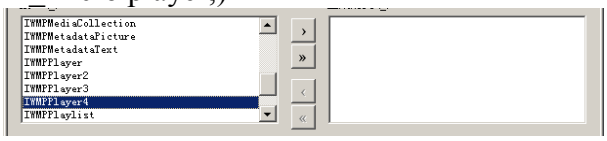
The Menu Item	ID	Property
OPEN	ID_OPEN	Open the media file
CLOSE	IDCANCEL	quit

Table 2. Modify the properties of the value of the properties dialog box

Property Value	Property	Set up
Menu	IDR_MENU1	True
Style	Popup	True
Border	Resizing	True
Minimize Box	True	True
Maxminze Box	True	True

The Function Of The Application Program Realization

Add the appropriate class for the Windows Media Player control, close the dialog resource (avoid mistakenly believe that the dialog box to add class), click the "project", "add", "ActiveX controls in the MFC class", such as the pop-up dialog box, select the CMICRO PLAYERPlayer4 interface class here is generated, and add a header file #include "CMICRO PLAYERPlayer4.h" in MICRO PLAYERDlg.h in the statement, At the same time to declare the control object(public: CMICRO PLAYERPlayer4 m_micro player;)



And then in the MICRO PLAYERDlg.cpp file in the location to DoDataExchange () function, ID number manually add the associated control DDX_Control IDC_OCX1 Windows Media Player control (pDX, IDC_OCX1, m_micro player); location: OnInitDialog () function to CMICRO PLAYERDlg:, add the following code.

```
BOOL CMICRO PLAYERDlg::OnInitDialog()
{   CDialogEx::OnInitDialog();
…
    CRect re;// Set the MediaPlayer control's size
    GetClientRect(&re);
    m_MICRO PLAYER.MoveWindow(&re,TRUE);
    SetWindowText(_T("My player")); //set the title
return TRUE;   // Unless you set the focus to the control, otherwise it returns TRUE   }
```

When dragging the dialog,In order to realize the MediaPlayer control with the dialog box the size of synchronous change,In the class wizard "message" tab, choose WM_SIZE, OnSize function overloading the system, add the following code:

```
void CMICRO PLAYERDlg::OnSize(UINT nType, int cx, int cy)
{   CDialogEx::OnSize(nType, cx, cy);
    // TODO: Add to this the extra initialization code
    if(IsWindowVisible())
    {    m_MICRO PLAYER.MoveWindow(0,0,cx,cy,TRUE);  }   }
```

MoveWindow(0,0,cx,cy,TRUE), The function is to realize the change of the specified window location and size.

The function prototype for:BOOL MoveWindow(HWND hWnd, int X, int Y, int nWidth, int nHeight, BOOL bRepaint);

Parameters:

hWnd: The window handle for the specified

x（0）:The new CWnd position on the left side of the specified.

Y（0）:The new CWnd position at the top of the specified.

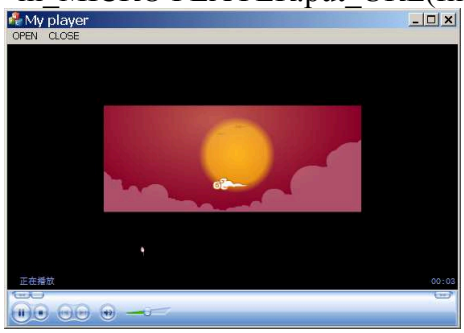
nWidth:The new CWnd width of the specified.

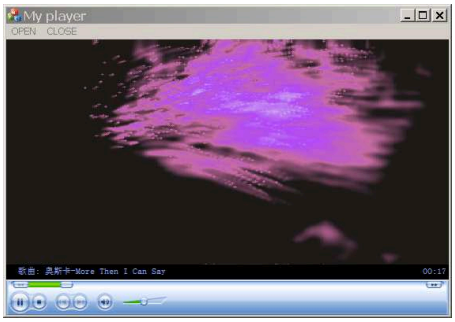
nHeight: A new highly specified for CWnd.

Brepaint: specifies whether to redraw CWnd. If TRUE, then CWnd as usual in the OnPaint message processing function receives a WM_PAINT message..

Use the wizard to "open" menu to add a message response function, ID_OPEN, for the CMICRO PLAYERDlg menu item under the add command message response function, navigate to the CMICRO PLAYERDlg.

```
void CMICRO PLAYERDlg::OnFileOpen()
{   // TODO: Add to this the extra initialization code
    CString fileName;
CFileDialog fileDialog( TRUE,NULL,NULL,OFN_HIDEREADONLY | OFN_OVERWRITEPROMPT,_T("Audio files, video files, movie file, all files(*.*)|*.*||"),this);
    if (fileDialog.DoModal() == IDOK)
    {   fileName=fileDialog.GetPathName();
        m_MICRO PLAYER.put_URL(fileName);     // Open play   }   }
```





Research Prospects

This paper designed the mini player to play flash files, midi files,mp3 files, avi files, support of the mainstream media files, meet the optimization function, use the player needs. In addition, can also study based expansion, more functions, improve the utility efficiency optimization player, playback.

The Application of Digital Information Technology in the Volleyball Game

Bai Zhen, Zhang Qiang

Student Physique Health Research Institution of Henan University Kaifeng 47500

Keywords: Digital Information Technology; Application; Course Selection; Training

Abstract. In this paper, the author starts from the application of digital information technology in making a further promotion of the scientific development in the China's volleyball game, exploring the application of digital information technology in our scientific volleyball course selection, training and matches. At the final conclusion, the author thinks that digital information technology will achieve a better, faster, more precise and stronger development in our volleyball game.

Foreword

At present, some foreign companies have already brought digital information technology into the volleyball game. For example, the DOTEPROJEETS (Italy) has developed the volleyball program; in China, there are few studies about the application of digital information technology in the volleyball game. The information technology will determine the development of the volleyball game and the increasing performance of the athletes to a great extent. The application of digital information technology is playing a greater auxiliary role in the volleyball training and matches. For our volleyball game, the author is going to discuss the application of digital information technology in terms of the scientific volleyball course selection, training and matches.

Digital information technology is a comprehensive application science that is integrated with mathematics, optics, electronics, photography, computer science technology and biotechnology, including the acknowledgment of digital information, message delivery and information processing, etc. The acknowledgment of digital information is to collect the index on the related physical training and competitions by means of the digital information technology. For example, it is able to collect the data about the athletes' physical quality, mechanisms and fighting ability as well as the volleyball game skills and tactics, etc; message delivery is an input and output process in view of the obtained data and analysis results by means of the wireless network access; information processing is to make the mathematical statistics on the image, digital information or the transferred digital information.

Scientific Course Selection

In the 21sth century, the studies about the scientific volleyball course selection is the comprehensive multi-disciplinary studies as well as the actual results of the comprehensive application on the course selection, combining with the coaches' training experiences, establishing the scientific and simple course selection ways; while the advanced technology is integrated with the research achievements of all the subjects, it is possible to set up the effective course selection model for the athletes. Meanwhile, it is able to simplify the complicated course selection ways, establish the fast feedback system for the athletes in each sports program so as to improve the talent rate. The digital information technology is applied into the course selection for the athletes, integrating all kinds of the multi-disciplinary research results into one, adopting the comprehensive research plans with the multi-disciplinary and indicators, and establishing the efficient and scientific course selection model. The digital information technology on the course selection for the volleyball athletes is to collect the comprehensive index about their physical shapes, physiology mechanism, biomechanics, psychology and genetics and others for the foreign and domestic excellent athletes. On the basis of the mathematical statistics, it is able to build up the talent cultivation database for the domestic and foreign excellent athletes; with the growth standards of the children and the juveniles, it is able to set up the scientific course selection model database. And

then the comprehensive indexes for the corresponding children and juveniles will be stored in directly going on with the database processing for the scientific volleyball course selection. The final research conclusion will provide the evidence for the volleyball course selection in improving the talents rate.

Scientific Training

3.1 Physical Quality Training

The application of the digital information technology on the physical quality training draws support from the advanced scientific technology like bio-sensing technique and remote sensing technology to test the changing index of the physical mechanism for the athletes. The test results will be stored and processed. There comes the final feedback information that is used to monitor the athletes' physical quality training.

In the volleyball game, the application and construction of digital information technology in the physical quality training starts from the remote test of the physiology index by means of bio-sensing technique and remote sensing technology in the game. In this way, it is able to collect the changing index of the athletes' body mechanism of which the corresponding data will be stored in making the mathematical statistics, revealing the energy metabolism characteristics and rules and setting up the databases for the changing index of the athletes' body mechanism; and then it is able to monitor the athletes through bio-sensing technique and remote sensing technology so as to acquire the changing physiology data about the athletes in the training. The obtained index and rules about the athletes' body mechanism will be processed of which the final feedback will provide the scientific evidence on the reasonable control and training for the coaches.

3.2 Skills & Tactics Training

3.2.1 Single Skill Action Training

On the basis of the three-dimensional camera technology and sports biomechanics, the application of digital information technology on the single skill action training is to analyze the single skill action, presenting the improvements on the reasonable skill action. The construction of digital information technology on the single skill action starts from the three-dimensional camera technology for the athlete's skill action. And then it is possible to enter the obtained image in the computer so as to make the sports biomechanics analysis. There comes the final analysis results. The coach will be able to give the intuitive guide for the athletes based on the analysis result of the image and skill action so that the athlete will find out the primary issue in the process, have the efficient understanding on the skill action concept and present the right movement. For some athlete, the special trainings are necessary to correct the wrong movements as soon as possible. In this way, the athlete will present the right dynamic modes about the movements in improving the athlete's single technique standards. According to the analysis results of the skill action as well as the characteristics and rules of the single skill action, it is able to assign the scientific and reasonable training and make the special training (for example, it is allowable to develop the muscle training that is affective to the single skill action, etc). In this way, it will improve the athletes' special quality and techniques in presenting the reasonable and scientific skill action. The efficiency of skill action is also increased.

3.2.2 Team Skills & Tactics Training

The application of digital information technology in the team skill and tactics training starts from the collection of the volleyball skills and tactics and write the statistics system about the volleyball skills and tactics; through the three-dimensional camera technology and voice control, it is able to obtain the team skills and tactics training materials, make the statistical analysis of the field tactics based on the action skill statistics system, seek for the more reasonable tactics so as to improve the team skills and tactics level. The coaches will not only give the more precise field guide with the analysis results, but also make the immediate training discussions with the team members in the ending of the game so that the team members will illustrate their performances outside the field, discover, consider and solve the problems in the role of the coach so that they will have the good

understanding about their performances and the opponents' performances. In this way, it will improve the team fighting ability and the athletes' skills and tactics.

Scientific Matches

4.1 Preparation Stage

Before the match, it is known that the preparation meeting is necessary to analyze the skills and tactics of the competitors and the team. The traditional way is to watch the previous videos about the competitors for the coach and the team members. The coach will analyze the competitors' performance and the tactics. However, this kind of analysis is usually rough of which it will be hard to get the particular and exact conclusion. In this case, it will not be able to foresee all kinds of the complicated situations in the official match. The team members will be hard to completely understand the characteristics of the competitors. Especially, there are deadlock to open up a new prospect.

The application of the digital information technology will make a complimentary to the deficiency to the great extent. In the preparation meeting, the coach and the team members will be able to watch the video about the actual situations of the entire match. As well, it is able to analyze the digital information about the obtained image and message from the skill and tactics system. It is possible to present the skills & statics and team member performance at each turn and stage in the form of the digits. The team member and coach will get the particular and exact result. Hereby the coach and the team members will make the efficient thought preparation in adopting the team advantages and avoid the shortcomings. According to the condition of the competitors, it is able to design the tactics, enhancing the athletes' confidence and mental quality and making the enough preparation to win the game.

4.2 Underway

Sometimes, it is not satisfying to get the guide upon the observation of the coaches outside the field. Even the issue is discovered, it is hard to find out the solutions. In terms of the application of the digital information technology in the game, it is much clear to compare the skills & tactics and powers at both sides, put forward the reasonable tactics and provide the theoretical evidence for the field guide on the skills and tactics.

In the game, the application of digital information technology starts from the obtained match images through the three-dimensional camera technology. The stored image will be transferred into the digital information. The information will be sent to the computer by means of the wireless digital transmission system. With the application volleyball program software, all the field data will be got at the both side. The coach will achieve the final information to adjust the field arrangement in view of the analysis results. In this way, it is able to defend the opponents' offensive strengths and attack the vulnerability in arranging the reasonable skills and tactics.

4.3 Summary Of The Post-Matches

After the match, the summary is unavoidable in each match. In this way, it will discover the existing problem in a better way, propose the greater count measures, and make the preparation for the success of the following matches. With the digital information technology, the team members' performance and skills and tactics will be recorded in making the mathematical statistics and providing the reliable data analysis. The coach and the members will be able to propose the reasonable suggestions about the post-match in a better way. The team members will have a full understanding about their performance and find out the existing issues in offering the evidence for the training and the match. Therefore, it is better to enhance the athletes' volleyball skills and tactics.

Conclusions

The digital information technology will promote the volleyball game in an accurate, efficient and scientific way. The application of the high technology on the promotion of the skills and tactics will become the trend to develop the modern volleyball game. With the continuous improvement of our

volleyball game, it is required to set up the corresponding and suitable volleyball software in view of our skills and tactics. The application of the high technology will promote our volleyball game in a better, faster and stronger way.

The Application of Computer Digital Simulation Technology in the Technical Structure Study of the Martial Arts

Gao Meihong

(Sports Department of Zhengzhou Normal University Zhengzhou 450044)

Keywords: Computer Digital Simulation; Martial Arts; Action Technology Structure

Abstract. In this paper, the author adopts the literature review research methods, starting from the perspective of the sports science research methodology, and discussing the research methods and procedures of the computer digital simulation technology in the technical structure study of the martial arts. In the martial arts study, the author expounds the application methods, procedure, steps and functions of the computer digital simulation technology in terms of the establishment of the structural digital models of the human body, the procedures, data input, data pre-treatment and calculation of the computer digital simulation technology, the structure models modification of the martial arts, the new action skill model design as well as the application value of the computer digital simulation technology in the skill training.

Introduction

With the science and technology development and the demands of the modern sports development, the fast development of computer technology has laid the scientific foundation for the comparison, overlay, dynamics test, calculation and automatic analysis and others about the structural image of the action as well as the quantitative analysis and researches of the action technology structures. In particular, the computer digital simulation technology is accessible for the martial arts experts and the coach to foresee the function and results of the action skills in the design stage. In this way, it has created a scientific and practical road for the researches of the martial arts technology structure characteristics as well as the best action technology structure. In light of the improvements of the martial arts technology structure or its re-construction, the application of the computer digital simulation technology in the martial arts action technology structure researches. Therefore, its research cycles will be greatly shortened in enhancing the feasibility or the actual application value of the martial arts technology structure design scheme, as well as the control level and training efficiency of the martial arts skill training.

The Establishment of the Digital Simulation Model of the Martial Arts Technology Structure

The computer digital simulation technology is the powerful tool to analyze, investigate and design the complex system for the human body motion in the computer. This technology has affected numerous scientific researches of the sports programs, such as. This technology has fully revealed the links between its external forms and the inherent nature, the principles, the establishment of the action technology structure and its development rules. In the martial arts technical structure studies, the human body is usually simplified as the multi-particle model or the digital model of the multiple rigid systems in light of the characteristics of the human body movements, the purpose, the rules and characteristics of the martial arts technology. The motion system like bones, muscles, tendons and other organizations will be processed as the forces in many links so as to have the multiple factors to affect the action skill structure in the model. In this way, it is able to establish the kinematics equation, dynamics equation and biology equation for the martial arts technology structure. For the independent generalized coordinates, the ordinary differential equations is often adopted in the skill action studies; for the dependent generalized coordinates, the differential algebraic equation is often adopted. These equations are high-order and highly coupled nonlinear. At very rare cases, the results are artificially solved. Typically, the final answer is got through the computer.

The Methods & Procedure of the Computer Digital Simulation Technology

3.1 The Methods of the Computer Digital Simulation Technology

The computer digital simulation procedures and methods in the models of the martial arts action structure include the original parameters input and calculation, the partial skill actions, the description of the entire motion dynamic (static) structure characteristics, the principle of the formation of the martial arts technology structure, etc. This kind of procedure is called as computer digital simulation procedures or numerical simulation technology. In the practice, there are forward or reverse calculation issues on the application of the computer digital simulation technology. For example, when the motion state of the human body (such as the motion space and time characteristics of the partial action) is known in each part, it needs to solve the mechanical conditions (such as myotility resistance, link resistance, the internal force transfer and the transfer of the human body angular momentum, external force, etc.) during the formation process of the skill action structure.

During the calculation process of the computer digital simulation technology, the additional constraints on the mechanics shall be increased so as to ensure the best combinations about the input value, and complete the best design about the martial arts action technology structure. With the accurate parameters in the digital simulation models, the final results will be reflected as the real structure characteristics of the motion state. The received results in the martial arts action skill researches will be featured as the strong predictability and the extremely practical guidance. For example, the American sports biomechanics experts Dr Lille had made the technical diagnosis for the throwing athletes Wilkinson. Through the computer numerical simulation technology, he had simulated and calculated the action space, velocity, force and momentum transfer parameters in the process. These high-orders, highly coupled nonlinear equations had offered the optimized action technology plans for Wilkinson during the process of throwing. With the scientific theory, these researches have provided the scientific guide for the optimization of the athletes' movements. It is significant to improve the sports science.

3.2 The Computer Digital Simulation Application Process

The computer digital simulation process is involved into many aspects. For instance, according to the investigated subjects and tasks of the martial arts action technology structure, it has created the digital models, the sports biomechanics equation, software application or writing, debugging, data checking and correction, feedback adjustment or control and others in the multiple rigid body system and in a continuous and dynamic way. The working flows of the best action technology structure of the finally established martial arts are stated as follows:

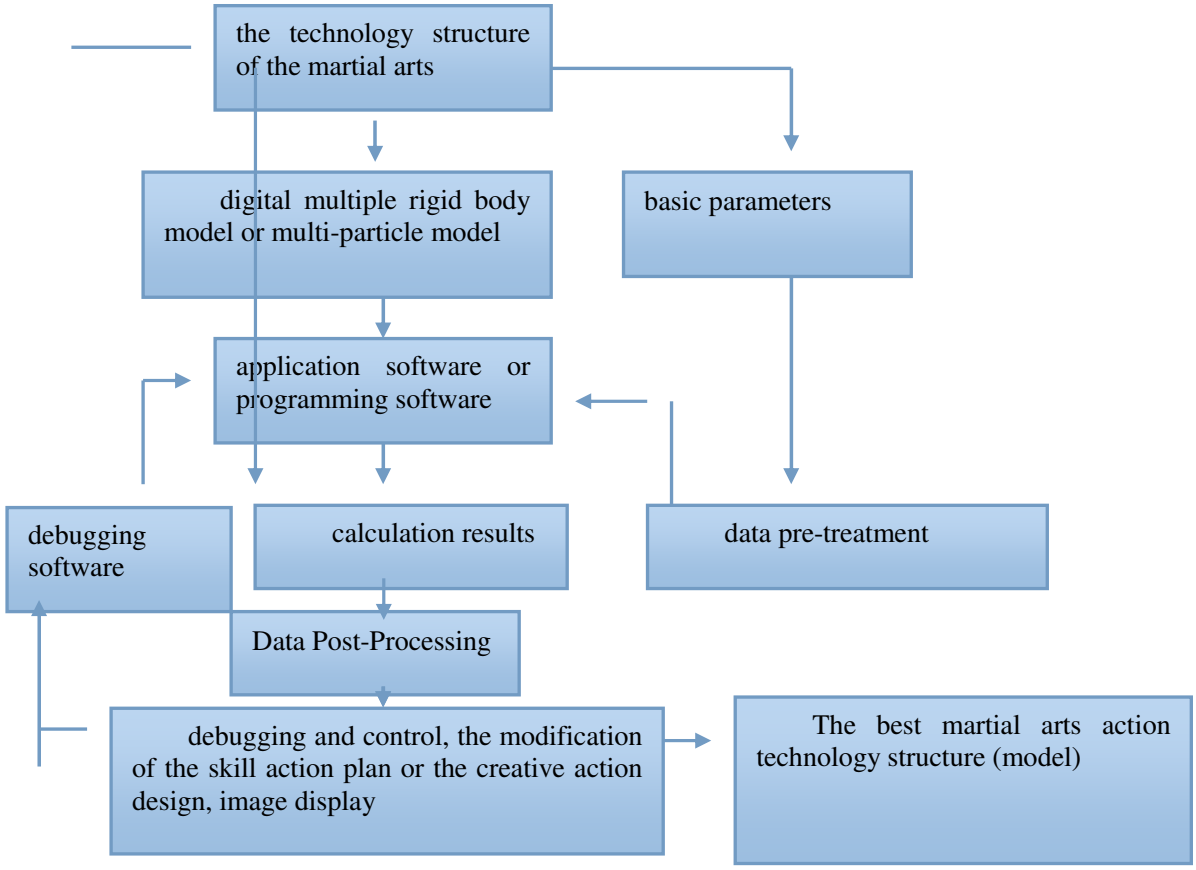

Figure 1 The working flow chart of the computer digital simulation technology

The Simulation Procedure and Steps of Computer Digital Technology

With the rapid development of the modern electronic computer technology, much computer application software is developed in relation to the rigid system mechanics model in the current market. This software is used to solve the forward and reverse issues about the multiple rigid system of the human body in terms of kinematics and dynamics. Since all the movements are constrained by the basic mechanics and biology principles in the martial arts, the digital simulation technology is good at solving the quantitative analysis of the martial arts action technology structure. The steps of the computer digital simulation technology include data input, data pre-treatment, simulation calculation, post-processing, the skill action plan modification, the creative movement design as well as the post-processing and the image display.

4.1 Data Input

Data input are comprised of the kinematics parameters of the martial arts technology structure from the three-dimensional photographic films or the plane videos, the kinetic parameters and inertia, moment inertia and other biomechanical parameters from the electronic loading system. The data are statistically entered. Its filtering, modification and smoothing procedure can be re-confirmed and modified on account of the wrong or suspicious data.

4.2 Pre-Treatment Data

The data pre-treatment refers to the conversion of the data coordinates, error processing, time synchronization processing, etc. According to the films or videos, the action space is generally featured as the inertia and inertial reference coordinates (such as background reference mark, human body structure axis, etc). The coordinates of the computer simulation calculation is usually based on the principle inertial axis of the human body rigid model. Therefore, it needs to transform the coordinate of the original data in the earlier stage, make the statistics, eliminate the singularities in the error processing, and smooth the complete data set. Time synchronization processing refers to the coincidence of the plane image space data and time characteristics, or the synchronization

correction of the mutually perpendicular plane image data in the three-dimensional photographs. The data pre-treatment works produce the direct influence for the accuracy of the system calculation results.

4.3 Computer Simulation Calculation

Upon the correct data pre-treatment stage, it is able to get the whole space motion process of the martial arts actions on account of the dynamics calculation equation, verifying the accuracy of the simulation program by comparison of the data with the actual image. By comparison of the simulation calculation images with the real motion images, the basically matching track indicates that the computer numerical simulation calculation is consistent with the actual situations. The results will offer the great guidance function for the improvement and re-engineering of the martial arts action technology structure as well as the sports training and practices.

4.4 Martial Arts Action Technology Structure Modification & New Action Technology Structure Design

The computer numerical simulation technology is an important solution to modify the partial actions and design the new optimization action skills. Since the changes of the images can be described by the mathematics, the automatic computer identification system is accessible for the entire motion image to change with the modification of the partial actions. If the observed results are satisfying in the computer display, it is worth to try the modification or new action design about the martial arts skill actions. It is much helpful for the coach and the athletes in the martial arts training process, especially for the basic action confirmation of martial arts and the design of the high, difficult and new movements. While the coach has some new ideas, it is able to prove the feasibility and efficiency of the simulation program, and then make the actual attempts so as to decrease and prevent the sports trauma, enhance the feasibility and safety of the martial arts action training.

4.5 Data Post-Processing& Image Display

According to the research contents and task requirements, the obtained computer digital simulation data shall be displayed in the different ways. The computer digital simulation procedure is featured as the data conversion functions of which the results will be shown in various kinds of the images. The procedure is called as data post-processing. The final technical motion images shall be much intuitive and reasonable. During the process of the optimal technical solutions, these connective images from the computer digital simulation calculation will have the important and direct effect on the modification and innovation of the martial arts action technology structure solutions.

The Application Value of Computer Numerical Simulation in the Skill Training

The application and function of the computer digital simulation and the animation technology researches on the skill actions are featured as: (1) The computer digital simulation takes use of the three-dimensional ways for the martial arts space structure, explaining its kinematics, dynamics and biological characteristics in the animation form. The athletes are easier and quicker to master the essentials of the skills so as to greatly enhance the overall training level and action skills

（2）Action choreography, simulation and reasonable action design system can design the new action technology scheme and standardize the action skills. Through the computer numerical simulation technology, it is able to edit, modify and design new action, choosing from the various scheduling results, and giving the optimization technology solutions, establishing the martial arts action technology structure modes and conducting the skill teaching and training.

（3）Through the comparison of the simulation results and the skill action training, it is able to make the quantitative and comparative analysis on the martial arts action technology structure, make the technique diagnosis, and display the analysis results in the form of the images of which the results are comprised of the human body space state changes, focus trajectory changes, displacement, velocity, acceleration, force and moment function, etc. In this condition, it is able to make a deep comparison analysis about the action mode and the athletes' technical action. The

athlete's training action and standard analog action will be shown in the same screen so as to make the technical diagnosis from the same view point to the synchronous contrast way. According to the martial arts action technology principle, it is able to design the directive scheme for the athletes.

Conclusions

The computer digital simulation technology is still a great topic in the martial arts action technology researches. The counterparts at home and abroad have achieved some successes in the computer digital simulation technology and calculation of the human body motion analog. Due to its complexity, the artificial tedious parameters are hard to fully meet the requirements in the sports practice. With the high-speed development of the modern science and technology, the computer digital simulation technology will play a greater role upon the combination of the constant martial arts action technology structure researches.

The Application of Computer Numerical Simulation in the Sports Science Study

Shangguan Yiqin

(Sports Department of Henan Agricultural University Zhengzhou 450002)

Keywords: Computer Numerical Simulation; Action Skill; Rigid Body Models

Abstract. In this paper, the author uses the literature review methods to talk about the application of the computer numerical simulation technology, combining the research methods and features of the sports science. In the sports science study, the author expounds the application methods, procedure, steps and functions of computer numerical simulation in terms of the establishment of the digital simulation model of the human body motion, the procedures, data input, data pre-treatment and calculation of computer numerical simulation, the technical plan modification of the human body movement, the new movement design as well as the application value of computer numerical simulation in the skill training.

In the sports teaching and training, the athletes' skill action are usually photographed and analyzed through the camera. However, it only makes the simple review on the athlete's single skill action. It is undesirable on the quality and comparative analysis in terms of the kinematics, dynamics, biology of the action skills. With the high development of the modern computer technology, it has laid the scientific foundation for the comparison, overlay, dynamics test, calculation about the images of the skill action. In particular, the computer numerical simulation technology is accessible for the coach to foresee the results of the action skills in the design stage so that the coach will be able to give the best action skill design. In view of the action skill improvement or re-construction, the study cycles are greatly shortened in enhancing the feasibility of the action skill design plan and its actual value.

The Establishment of the Digital Simulation Model of the Human Body Movements

System simulation is the powerful tool to analyze all kinds of the complex system in the computer. This technology has affected numerous scientific researches, engineering areas and non-engineering areas. For the action technology research, the human body is usually depicted as the multiple rigid system models in light of the characteristics of the human body movements, the purpose, the rules and characteristics of the action skills. The motion system like bones, muscles, tendons and other organizations will be processed as the mutual force and kinematics of the rigid body system so as to establish the kinematics equation, dynamics equation for the human body movements. For the independent generalized coordinates, the ordinary differential equations is often adopted in the skill action study; for the dependent generalized coordinates, the differential algebraic equation is often adopted. These equations are high-order and highly coupled nonlinear. At very rare cases, the results are simplified. Typically, the value is got through the computer.

The Methods and Procedure of Computer Numerical Simulation

2. 1 The Methods of Computer Numerical Simulation

Through the computer, the human body motion methods include the original parameters input and calculation, the technical action, the principle formation, etc. This kind of procedure is called as numerical simulation. There are forward or reverse calculation issues. For example, when motion state of the human body (such as the motion space and time characteristics) is known in each link, it needs to solve the mechanical conditions(such as myotility resistance, link resistance, the internal force transfer and momentum transfer of the human body, external force, etc.) during the formation process of the skill actions. In the computer numerical simulation calculation process, the additional constraints on the mechanics shall be increased so as to ensure the best combination about the input

value, and complete the best design about the action skills. With the accurate parameters in the numerical simulation models, the final results will be reflected as the real motion state. The received results in the action skill research will be featured as the strong predictability and the extremely practical guidance. For example, the American sports biomechanics experts Dr Lille had made the technical diagnosis for the throwing discus athletes Wilkinson. Through the computer numerical simulation technology, he had simulated and calculated the action space, velocity, force and momentum transfer parameters in the process. These high-orders, highly coupled nonlinear equations had offered the optimized action technology plans for Wilkinson during the process of throwing the discus. With the scientific theory, these researches have provided the scientific guide for the optimization of the athletes' movements. It has played a significant role for the improvements of the sports science.

2. 2 The Computer Numerical Simulation Process

The computer numerical simulation process is involved into many aspects. For instance, according to the investigated action skill subjects, purpose and tasks, it has created the digital model, the sports biomechanics equation, software application or writing, debugging, data checking, feedback adjustment or control and others in the multiple rigid body system and in a continuous way.

The Computer Numerical Simulation Steps

With the rapid development of the modern electronic computer technology, many computer application software are developed in relation to the rigid system mechanics model in the current market. This software is used to solve the forward and reverse issues about the multiple rigid system of the human body in terms of kinematics and dynamics. Since all the movements are abide by the basic mechanics and biology principles, the numerical simulation is good at solving the action skill issues of the human body. Its simulation steps include data input, pre-treatment, simulation calculation, post-processing, the skill action plan modification, the creative movement design as well as the post-processing and the image display.

3. 1 Data Input

Data input are comprised of the kinematics parameters from the three-dimensional photographic films or the plane videos, the kinetic parameters and inertia, moment inertia and other biomechanical parameters from the electronic loading system. The data are statistically entered. Its filtering, modification and smoothing procedure can be re-confirmed and modified on account of the wrong or suspicious data.

3. 2 Pre-Treatment Data

The data pre-treatment refers to the conversion of the data coordinates, error processing, time synchronization processing, etc. According to the films or videos, the action space is generally featured as the inertia and inertial reference coordinates (such as background reference mark, human body structure axis, etc). The coordinates of the computer simulation calculation is usually based on the principle inertial axis of the human body rigid model. Therefore, it needs to transform the coordinate of the original data in the earlier stage, make the statistics, eliminate the singularities in the error processing, and smooth the complete data set. Time synchronization processing refers to the coincidence of the plane image space data and time characteristics, or the synchronization correction of the mutually perpendicular plane image data in the three-dimensional photographs. The data pre-treatment works produces the direct influence for the accuracy of the system calculation results.

3. 3 Computer Simulation Calculation

Upon the correct data pre-treatment stage, it is able to get the whole space motion process of the human body on account of the dynamics calculation equation, verifying the accuracy of the simulation program by comparison of the data with the actual image. By comparison of the simulation calculation images with the real motion images, the basically matching track indicates that the computer numerical simulation calculation is consistent with the actual situations. The results will offer the great guidance function for the improvement and re-engineering of the action technology as well as the sports training and practices.

3. 4 Human Body Motion Changes & New Action Design

Computer numerical simulation technology is an important solution to modify the partial actions and design the new optimization action skills. Since the changes of the images can be described by the mathematics, the automatic computer identification system is accessible for the entire motion image to change with the modification of the partial actions. If the observed results are available in the computer display, it is worth to try the modification or new action design. It is much helpful for the coach and the athletes in the training process, especially for the basic action confirmation of human body and the design of the high, difficult and new movements. While the coach has some new ideas, it is able to prove the feasibility and efficiency of the simulation program, and then make the actual attempts so as to decrease and prevent the sports trauma, enhance the feasibility and safety of the skill training.

3. 5 Data Post-Processing& Image Display

According to the research contents and task requirements, the obtained computer numerical simulation data shall be displayed in the different ways. The computer numerical simulation procedure is featured as the data conversion functions of which the results will be shown in various kinds of the images. The procedure is called as data post-processing. The final technical motion images shall be much intuitive and reasonable. During the process of the optimal technical solutions, these connective images from the computer numerical simulation calculation will have the important and direct effect on the modification and innovation of the action technology solutions.

The Application Value of Computer Numerical Simulation in the Skill Training

The application of the computer data simulation and the animation technology researches are featured as:

(1) The computer data simulation takes use of the three-dimensional ways for the skill action analog, explaining its kinematics, dynamics and biological characteristics in the animation form. The athletes are easier and quicker to master the essentials of the skills so as to greatly enhance the overall training level and action skills.

(2) Action choreography, simulation and the reasonable action design system can complete the new action technology scheme and standardize the action skills. Through the computer numerical simulation technology, it is able to edit, modify and design new action, choosing from the various scheduling results, and giving the optimization technology solutions, establishing the action skill modes and conducting the skill teaching and training.

(3) Through the comparison of the simulation results and the skill action training, it is able to make the quantitative and comparative analysis on the skill action, make the technique diagnosis, and display the analysis results in the forms of the images of which the results are comprised of the human body space state changes, focus trajectory changes, displacement, velocity, acceleration, force and moment function, etc. In this condition, it is able to make a deep comparison analysis about the action mode and the athletes' technical action. The athlete's training action and standard analog action will be shown in the same screen so as to make the technical diagnosis from the same view point to the synchronous contrast way. According to the action technology principle, it is able to design the directive scheme for the athletes. The computer numerical simulation calculation technology is still a difficult and hot issue in the sports science researches. The counterparts at home and abroad have achieved some successes in the computer numerical simulation calculation science researches of the human body motion analog. Due to its complexity, the artificial tedious parameters are hard to fully meet the requirements in the sports practice. With the high-speed development of the modern science and technology, the computer numerical simulation technology will play a greater role upon the combination of the constant action technology researches.

Security Protection Model of QR Code Scanning Software[1]

Zhu Lei

Central University of Finance and Economics Beijing 100086, China

iamzzzz@163.com

Keywords: Attack, QR code,Security Model

Abstract. A QR code is more and more widely used in recent years. The two-dimensional bar-code can be seen in business cards, advertising, or web page and everywhere. But there exist some potential security dangers behind scanning those codes. Hence it have being obstacles to the widely using of QR code scanning software in some degree. This article analyzes several kinds of known attacks tricks through the QR code, and puts forward that the most efficient technology in protect the QR code scanning software is code encryption and white list . Finally An Android security protection model is given.

Introduction

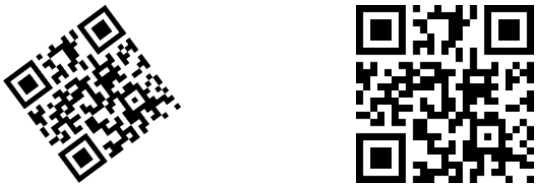
In recent years, two-dimensional code has become one of the most important entrance of mobile internet. The two-dimensional code is convenient to connection freely online and offline; therefore wins users' praise highly and popular increasingly . Two dimensional code is very simple to use, as long as the user scans the the two-dimensional bar-code with the camera of a mobile phone installed with scanner software. Information of pictures can quickly display on the mobile phone screen, avoiding the tedious operation and error input. But it is very easy to be infected with the virus when the user scans some unknown two-dimensional code, which may racking up big bills for user, or leaking privacy information property information. Therefore, how to strengthen the security protection ability of this kind of scanning software is becoming increasingly concerned problem of the software developers[1].

Theory of two-dimensional code

Many kinds of two-dimensional code exist, such as: PDF417, Code 16K, Data Matrix, Maxi Code etc.. But the basic principles of two-dimensional code are the same. QR code [2]is a matrix two-dimensional code, originally developed by the Japan Inc., and finally become a standard. Two dimensional QR standard code is square, with black and white color. At the 3 corners of the QR code square are image like Chinese "回" word. The 3 image can help software locating the correct position of two-dimensional code. The user does not need to complete alignment, and the scanning angle is not restricted. The data can still be read correctly. Elsewhere in the QR code is black and white, indicating the 1 and 0 in binary system. In order to improve the fault tolerance, QR code include more bits information besides the real meaningful words. This technical is called Reed -Solomon coding. This code can correct many unexpected errors.

In addition, many color blocks are used to correct, and determine the copyright information. The scanning process of two-dimensional code is to translate the information contained in the image; the complete decoding process is as follows.

Location. The three angles of QR code are "回" like images,which can be seen as a mark.The size and location of the"回" like image are required by the QR code standard; Therefore, no matter how image rotation, it can rotate the QR code image to the standard forward position,through matching the mark position.The original and rotated image are shown in figure 1.



（a）original image （b）rotated image

Fig 1 The operation of location

Calibration. The shooting angle of the QR code image can be arbitrary. Therefore the forward image after locating may be not a standard square, which is likely to be beveled, one side large and the other short, as shown in figure 2. Calibration process use the mark of the QR code in the middle left lower side positon to enlarge the image to a suitable size.

Fig 2 Beveled QR code

Decoding. In this process the software read the contents of the image according to the image of the black and white color block. Every black and white block represents a binary "1" and "0". Hence the process of decoding is to read these the binary data according to its position in the image.

Error correction. The data cannot be directly used after decoding, because most of the QR code achieved by decoding process contain errors.Error correction process can remove these errors in binary, and provide a correct binary data.

Translate. Binary data will be converted into the text messages that can be recognized.

Attacking ways

People cannot directly read the information in the QR code image, but it is very simple for scanning software; Most scanning software provides intellisense and content recognition after getting the QR code image information, so greatly improve the user experience.But it also give the attacker a opportunity to attack.At present, the common attack ways are list below.

Trojan attack. Trojan embedded into the normal web pages is commonly known as the Trojan horse attack. Infected Trojan web pages,and even those seemingly normal web, can be downloaded by the user's browser, while users know nothing.The purpose of Trojan distributors allure the users to download these web pages to its local computer, so as to attack and control the user's computer.Trojan attack have different ways, among them the easiest way is to insert a hidden frame in the web page.For example, inserting the following HTML code into a normal web page.

<iframe src=http://dangerous website width=0 height=0></iframe>

In the web frame, the properties of width and height are equal to zero, which means that the frame are invisible. While the victims visit a seemly normal web page, the hidden dangerous http://dangerous website is visited at the same time unwittingly.

Phishing attack. Phishing is the ancient attack way . By sending a large number of deceptive information, the attacker is intent to induce the recipient to give sensitive information (such as user name, password, account ID and credit card details).The most typical QR code phishing attack way is the way by sending a coupon fishing users scan QR code to access the website.The web address (URL) are encoded into QR code, so the user is convenient to visit the web site by just scanning. The fishing site intent to imitate the URL and outlooking of famous sites. So it is easy to leak their personal information to the attacker, if you think the fishing web site is the real web site in your impression.

Inject attack. Command injection attacks has two ways, one is to attack mobile system itself, the other one is to attack the database system . Attacks on mobile phone system can take advantage of the mobile phone system engineering code. Most of the engineering code are harmless. But if a QR code

contains some important system engineering operation code, the user may suffer user data loss and the system reset.

Another kind of injection is against the database. The same attacks as that of website, the place where need input from a keyboad changes into scanning QR code. If there have no validity detection to the QR information, it might cause problems with executing query command in the database. For example: to construct the SQL query statement

SELECT a,b FROM c WHERE a_id = '123';DROP DATABASE pubs.

In this query, the former part is normal SQL query, ";" semicolon marks the end of the SQL statement. Behind the semicolon is a very dangerous operation SQL statements, it will clear away the pubs table in the database. User accidentally scan the QR code, if he has the authority, *pubs* table will be cleared, then the entire database will collapse. Therefore command injection attack need to strictly guard against.

These are a kinds of used attacking way by the QR code at present. In essence, the QR bar code is only a type of encode, and itself does not contain a virus. But some malicious information may be embeded into a QR code, then attack can be conductted.

Protect Module

The application scenario of QR bar code scanning software has two kinds: one is on a handheld device, another is on the scanning terminal. Command injection attacks are the main attack method in the scanning terminal, while handheld devices receive a variety of attacks, most of which are Trojan attack. In order to protect the 2D bar code scanning software, we introduce the encryption technology and the white list technology in our model.

QR code encryption. The most effective way to prevent QR code command injection attacks is to use the encryption code[3]. Anyone can use the software to generate QR code image, thus the attack code is very easy to be added in the 2D QR image. Once the two-dimensional codes are encrypted, scanning software needed to decrypt and then run; without proper encryption the information cannot be correctly interpreted, not up to attackking. Process of two-dimensional code decryption can be carried out after reading the information of cameras, and then the decrypted information can be pass on the other modules.

White list. QR code encryption technology is very effective to prevent injection attack. Only people who holds the key can generate QR code recognized by the software system, but this technical are not suitable for some third party application. These third party software usually adopt plain code, such as scanning and download software etc.., hence it must be at the risk of being attacked when read these QR code images.

The conservative security way is white list technology, which is simple but effective for software.The software application only redirects to the specified websites (white list), while the other web sites are not permit to redirects. On the software design, white list filtering works behind the step of the scanning.

System Frame. The position of the two kinds of technology use the same position, so you can build a unified model for protection the scanning software.

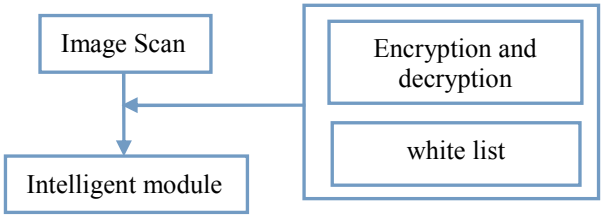


Fig. 3 Security Protection module

After reading the information in the QR code image by opening the camera of the phone, the software can't directly jump to the websites or intelligent processing. It need to go through the security encryption or white list processing contained in the protection module.The System Frame and the security model as shown in figure 3.

Key technical. A lot of QR code scanning software are designed with the help of the public API or a software package[4][5]. Among them the ZXing bar code image processing library is an open source software package that is very easy to implement the QR code scanning and decoding. The function's calling way and security module code position are set as follows:

```
//QR CODE SECURITY SCANNING MODULE
private PreviewCallback mPCallback = new PreviewCallback() {
  public void onPreviewFrame(byte[] data, Camera camera) {
    int pWidth = camera.getParameters().getPreviewSize().width;
    int pHeight = camera.getParameters().getPreviewSize().height;
    PlanarYUVLuminanceSource source = new PlanarYUVLuminanceSource(
      data, pWidth, pHeight, 0, 0, pWidth, pHeight, false);
    BinaryBitmap bitmap = new BinaryBitmap(new HybridBinarizer(source));
    Reader reader = new QRCodeReader();
    try {
       Result result = reader.decode(bitmap);
       String text = result.getText();
       ...//security processing function
       Intent intent = new Intent();
       ...//intelligent processing function
       ...;
    } catch (Exception e) {
  ...
```

The above code gives the location of the security processing function and the intelligent processing function. Due to the different way of the QR bar-code encryption and decryption, we can not give detailed processing code. However, after security processing, the program returns either errors or correct useful string which could be used for the following intelligent processing.

Conclusion

The article discusses a variety of attack types which are easy to be suffered by the QR code scanning software. And a software security model is accordingly put forward . In general, the more security designing in the software, the worse programming efficience and worse use experience. On the contrary, the software will be easily attacked if there have no security protection.Appropriate and targeted design is the starting point of this safety model proposed in the paper. With the wide application of two-dimensional code technology, more and more special 2D bar-code scanning software will be boomed in the market. An excellent security protection designing will make the application of this kind of software more wide.

Keywords: Tibetan,web public opinion,SVM,sentiment classification

Abstract. Tibetan Web text has increased rapidly in recent years. According to mining and analyzing the data about user's comments, we could identify the Sentimental tendency and evolution. Therefore we can better understand the user's behavior. Hot Tibetan public opinion analysis at the same time also can give enterprise, government and other institutions to provide important decision-making basis. The paper first describes SVM algorithm. Then the study of public opinion and target Tibetan Web Sentiment classification is defined and described, after that the paper gives the basic ideas and experimental research program. Finally, we summarize the achievements and shortcomings of Tibetan sentiment classification, as well as describe the challenges and the prospects of its development prospects.

Introduction

With the popularity of the Internet and the development of the Tibetan information technology, more and more Tibetan websites appeared. Nowadays,a large number of people choose the network to publish their attitude. Network comments are as a kind of UGC (User Generated Content) data, the user's perception of an event and point of view, and a kind of network public opinion information. However, faced with a flood of information of Tibetan review, it is very difficult to get information about the actual about what we really need. Therefore, people often classify the Tibetan website according to Sentimental content. With respect to the relevant technical research increasingly sophisticated Chinese and English text processing techniques, Tibetan corpus construction, Tibetan word segmentation, Tibetan text classification and text clustering are still in the early stages[6,7].

SVM Algorithms

SVM (support vector machine) is based on a statistical learning method, which is the basis of the VC dimension theory and theoretical knowledge of the theory of structural risk minimization in statistical theory [1, 2, 3].

The actual problem is rarely linearly separable problems. Most of them are relatively complex non-linear separable problems. For simple linearly separable problems, we can use a linear function $f(x) = w \bullet x + b$ to classify the sample. For complex nonlinear problems by introducing a nonlinear mapping function to map the data from low-dimensional space to a high-dimensional space, then we could find the best hyper plane in a high-dimensional space. When looking for the best super-plane only need for inner product operation between samples, high-dimensional inner product space can be calculated using the favorable kernel function $K(x_i, x_j) = \phi(x_i) \cdot \phi(x_j)$ .You can say that the introduction of kernel function makes the support vector machine classifier into a generic classifier.

For a given sample: $\{(x_1, y_1), (x_2, y_2), ...(x_n, y_n)\}$, $x_i \in R^d$, $y_i \in \{+1, -1\}$. We adopt an effective nuclear function $K(x_i, x_j)$, and then a linear classification can be achieved after non-linear

transformation. It makes the problem of complexity greatly reduced. Nonlinear problem can be divided as follows:

$$\min_{w,b,\varepsilon} \frac{1}{2}\|w\|^2 \quad s.t. y_i(w \cdot x_i + b) \geq 1, i = 1,2,...l \tag{1}$$

According to Wolfe duality theory, we can get the following formula of the dual problem:

$$\max_a w(a) = \sum_{i=1}^{l} a_i - \frac{1}{2}\sum_{i,j=1}^{l} a_i a_j y_i y_j K(x_i, x_j) \quad s.t. \sum_{i=1}^{l} a_i y_i = 0, a_i \geq 0, i = 1,2,...l \tag{2}$$

Solving these Dual optimal solution $a*$, if $a*>0$, x_i is called Support Vector; if $a*_i = C$, x_i is called Border Support Vector; if $0 < a*_i < C$, x_i is called True Support Vector. Resulting in the decision-making function of the high-dimensional space:

$$f(x) = \mathrm{sgn}(\sum_{i=1}^{l} a_i^* y_i K(x_i \cdot x_j) + b^*) \tag{3}$$

$K(x_i, x_j)$ is called kernel function, when it satisfies Mercer condition and at the same time $K(x_i, x_j) = \phi(x_i) \cdot \phi(x_j)$, we can introduce kernel function method to solve the reality of complex nonlinear separable problems.

Algorithm Implementation

3.1 Tibetan text preprocessing

Experiment texts get from Qinghai Tibetan network broadcasting network, people's Tibetan network, China netcom, Tibetan xinhuanet multilingual Tibet channel.

Tibetan texts must be handled as follows: transcoding, segmentation, redundancy removal, in order to take over the text for further processing.

A text after processing as shown in figure 1:

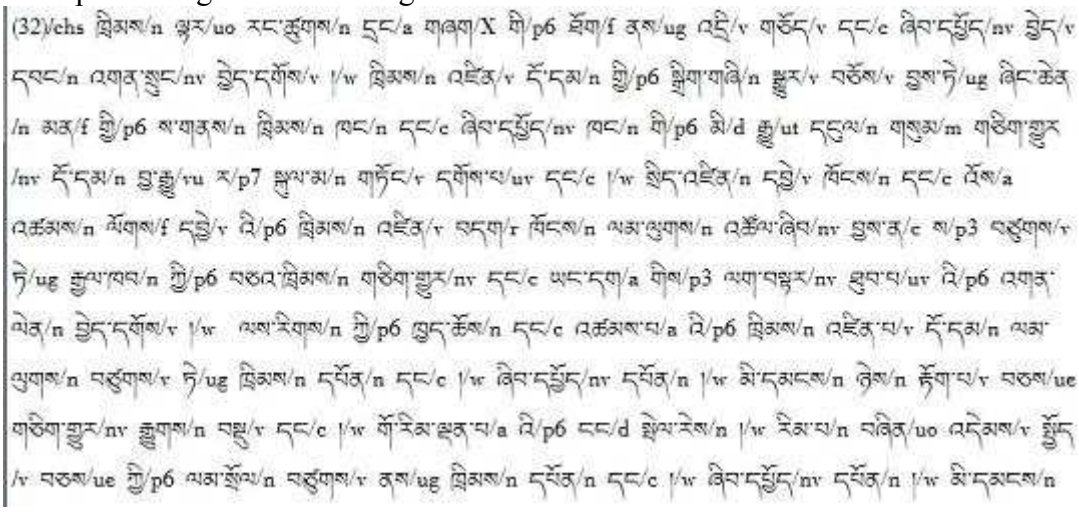

Fig.1

3.2 Tibetan text feature extraction and text representation

For all of the text sets extracted thesaurus created, if the text of a word as a feature, hundreds of thousands of feature is very common. How to distinguish a high degree on the category chosen words

is important. Firstly, it can reduce the amount of computation. Secondly, it could be able to improve the classification results.

The number of statistics for every term in documents is called terms frequency (TF). Calculated for each term of A, B, C, D.

A is the number of documents under this category contains the term;

B is not the number of documents under this category contains the term;

C is the number of documents under this category does not contain the term;

D is the number of documents not under the classification, and does not contain the term.

Each term eigenvalue calculated according to the formula:

$$x^2(C_j, t) = \frac{(AD-CB)^2 \times (A+B+C+D)}{(A+C)\times(B+D)\times(A+B)\times(C+D)} \quad (4)$$

All the eigenvalues order from big to small, and take out 1000 terms before each category. Cycle each category, the terms eigenvalue in all categories are merged into one text.

3.3 The data processing

The 700 documents is coming from the website by Web crawler, including 550 as a training set for classifier learning, and the remaining 150 as the test set. All the documents divided into political, economic, military, cultural and legal five categories by professionals. After handding the documents,such as transcoding, segmentation, redundancy removal ,we use Libsvm classification tools for data processing. Libsvm is an open source support vector machine (SVM) software package. It is developed by Professor Lin Chih-Jen and available for use. Libsvm is able to quickly and effectively classify and regress.

The data format of Libsvm is:

lable1 index1:featureValue1 index2:featureValue2 index3:featureValue3 ...

lable2 index1:featureValue1 index2:featureValue2 index3:featureValue3 ...

So,Tibetan text vector space model is expressed as follows:

3 11:0.136432 134:0.102896 162:0.368742 191:0.093873 273:0.334915 313:0.062247 385:0.103369 417:0.02399 470:0.317241 501:0.004156 ...

For example 3 11:0.136432 . Arabic numerals 3 representatives category ID, 11 representatives the term which the feature number is 11, 0.136432 is the features value (already scaled between 0 and 1 by svm-scale function)

Summary

Through experiment results, we found that the choice of the type of kernel function impact on the classification not so much. When we selected RBF kernel function we could get better classification results than we choose others type of keener function. From the beginning of this century, sentiment analysis on text information extraction gradually becomes a hot research field so that it is drew more and more attention. Meanwhile, with the continuous development of natural language processing techniques and machine learning techniques, subjectivity text sentiment analysis become possible else, and it would be gradually widely used.

Wuhan, 430023, China

email: zhl_wh@sina.com

Keywords: Web; semantic; grid environment

Abstract. Grid environment as the cross field of semantic web and grid computing, has received significant attention recently. Our workgroup develops a resource management semantic grid named RM-Grid to enhance information process accuracy and efficiency in heterogeneity environment. This paper describes the architecture of RM-grid, mainly introduces the data translation service of RM-Grid. It puts forward an ontology based common semantic model and an XML based data model, presents the data translation algorithm between different data sources and an adapter framework for accessing distributed heterogeneous resources as well.

Introduction

A multi-institutional semantic grid environment will contain many data sources, which maintain different types of data using different storage mechanisms. Data collection, translation and retrieval are the major tasks in such systems. So far, there have been several projects on service infrastructure for data management, such as Storage Resource Broker [1], Metadata Catalog Service [2], etc. Our workgroup develops a resources management semantic grid named RM-Grid, which aims to improve the ability of processing heterogeneous sources under dynamic, distributed environments. In this paper, we will introduce the architecture of RM-Grid and discuss the data translation service emphatically.

Architecture of RM-Grid

The logical architecture of RM-Grid is divided into three layers.

1) Client Layer

RM-Grid is presented to the users with client Layer. Grid Portal provides the users with graphic interfaces. Users could browse domain ontology and describe their requirement, Grid Portal will send the user request to RM-grid, and the grid then invokes a series of corresponding services and presents the result to user in Grid Portal.

2) RM-Grid components

The RM-Grid core components include:

a) Semantic Registry Service. It is used to the registry and discovery of services. Referring to the Web service registry center, we add the metadata to RM-Grid for service descriptions. The service metadata is saved in registry center in form of XML. When a grid user wants to create a service, he should adopt the concepts in ontology to describe it. So that, the users can make use of semantic matching to search services accurately.

b) Ontology Service. In order to support semantic process, we make use of ontology to translate between semantically heterogeneous XML data. Ontology provides a formal, shared specification of concepts, their relationships, and other realities of some domain, which can reduce or eliminate confusion of terminologies, enable computers to process domain knowledge more precisely and conveniently [3]. RM-Grid provides ontology service for the grid consumers to maintain and search ontology.

c) Data Translation Service. It will often be the case that institutions will have different methods for modeling data, which may be conceptually or semantically the same. It would be beneficial to both institutions to be able to translate between one another's data models such that each can leverage the other services. Data translation service is the way to share data and services using common models. This, of course, does not mean that the automatic structural or semantic data translation problem is solved. This simply gives a service architecture where data translation services are published and can be trusted between the two domains in which the data is translated and potentially accepted by others as the standard.

d) Agent Service. It is responsible for assisting consumers to make use of grid resource and services. Agent service generates for each user an agent service instance, which interacts with Grid Portal and invokes the service on behalf of the user.

e) Global Model Management Service. In order for services on the grid to communicate with each other, their data must be described in a format that is understood by each involved component. Referring to the multi-level models theory of database field, the RM-Grid provides a method for defining an XML schema based data model derived from an ontology conceptual model. The Global Model Management Service provides for the consumers some methods to create and register their models, i.e. the XML schemas. The consumer can search the Global Model Management for existing XML schemas and may use one that suits their need; He can version an existing schema by adding or deleting data attributes. Once the schema is created, it is registered with the Global Model Management so that other consumers can search for it.

f) Data Instance Management. Services on the grid will need a method for storing and querying data. This will be integral for service communication on the grid. Given valid credentials, data should be able to be stored across a series of heterogeneous loosely-coupled machines. The RM-Grid also provides the ability to allow trusted users to update, query and delete the data. Data are in form of XML.

g) Domain Specific Service. Domain Specific Service is a series of services abstracting from the usual domain specific functions. A domain specific service could accomplish a relatively complete function by invoking the corresponding services in the grid. In the running process of RM-Grid, it could add services dynamically.

h) Common Data Service. Common Data Service is a series of grid services providing for the whole virtual organization with common data process functions. It will be invoked by other grid services frequently.

i) Task Monitor and Management Mechanism. It is responsible for monitoring, scheduling and supervising the programs running in the RM-Grid, make the grid right and efficient.

j) Grid Qos Mechanism. It is designed for tracing the running status of RM-Grid and recording the quality of the grid services.

k) Grid Security Mechanism. It is responsible for supervising the security of RM-Grid

3) Resource Layer

Resource of RM-Grid is the autonomic systems, such as enterprise information system, file system servers, relation or object-oriented database system and so on. Since these systems present different structures and semantics result from that distinct data sources may use different modeling methods, making very difficult to share and exchange information, RM-Grid provides resource service to encapsulate heterogeneous resource, they have uniform interfaces, which make it easier to manage. The RM-Grid will allow the grid consumer create schemas which describe their data models, register and share these data models with other collaborators, manage and version them while new data types are added or deleted, facilitate translation between data models that have the same semantic meaning, but different structure, and create, integrate, and manage databases and data that conform to these data models.

Common data model

The Data Translation Service is responsible for managing the translation between heterogeneous representations. In RM-Grid, we make use of ontology to translate between semantically heterogeneous data. Ontology is the key technology to describe the semantics of information exchange. It is defined as "specifications of a shared conceptualization of a particular domain" [4]. Ontology specifies a common understanding of certain domain in terms of concepts, attributes, and relations that can be communicated across people and application systems, thus they facilitate knowledge sharing and reuse. Both ontology and XML schema [5, 6] provide vocabulary and structure to describe information, the difference is that ontology languages specify domain theories and XML schema provides integrity constraints for information sources. With regard to the relationship between them, we refer to the multi-level models theory of database field. Correspondingly, we could consider ontology is analogous as conceptual model, and XML Schema is analogous as data model, therefore, an XML-orient semantic data model can be derived from an ontology conceptual model by designing a mapping algorithm originating from ontology to XML schema. Deriving XML Schema from ontology means to map ontology concept entities, attributes and is-a hierarchy to XML document structure and tag set, and forming a new schema-level specification. As a consequence, XML documents validated by the XML schema will be compatible with ontology. Since XML tags and structures can express explicit domain knowledge, our approach improve information from the syntactic or representational level to the more abstract level of concepts and relationships, avoids semantic heterogeneity efficiently and realizes the consistent representation of unstructured information. Meanwhile, using standard semantic level tags based on ontology to annotate content can help the computers to extract semantic of information from XML documents automatically.

To solve the data translation in semantic heterogeneity environment, RM-Grid firstly makes use of ontology to provide a machine processable semantics that can be communicated between different data sources, and then translates between different data referring to the semantic data model deriving from ontology. The general idea can be expressed as follows:

–Each concept from the ontology generates an element type in the XML Schema.

–For each attribute the XML Schema defines a sub element or, an attribute of element.

–If the attributes represents a relation to another concept the attribute element has as content the respective concept element, otherwise its content model is simply atomic.

Data translation service

Semantic data model derived from ontology in above subsection is a common data model register in RM-Grid. Model translation service will translate the heterogeneous model in resource layer into the common data model, so that the systems in resource layer could realize data sharing and cooperation. Original systems in resource layer of RM-Grid have their own understand about domain knowledge. Each system uses different language or syntax to represent knowledge, which forms respective local semantic schema. Before discussing the model translation, we require that the resource layer could output data in XML. The information providers need to wrap their own unstructured information with XML. What we want to emphasize is the hypothetical heterogeneity, i.e. XML documents need not abide to any certain structures. So resource providers can implement the wrapping process easily.

There is an adapter framework, which is responsible for the translation.

1) Extract local semantic model. This step analyses XML documents and their XML Schema submitted by resource providers, extracts the XML elements and attributes tags from the documents, finds the meanings and characters.

2) Concept matching. The generation of semantic knowledge and integration of different local models depend on the result of concept matching to a great extent. Different from keywords matching, concept matching is the consequence of local semantic models. It is matched by attribute

and content. Initial stages of the process need human interference, which involves semantic knowledge construction. At first, we can construct a semantic knowledge base making use of synonymous dictionary and train it subsequently, expand fresh knowledge continuously. Concept matching produces vocabulary-mapping table.

3) Generation of semantic XML documents. According to VMT, adapter translates heterogeneous XML documents. Then referring to XML Schema derived from ontology, realizes the transition from local XML documents to global ones with XSLT programming.

Conclusions

This paper presents a resource management grid. Mainly introduce the data translation service of it. The main objective of the architecture is to improve the capabilities of semantic processing and the translation between ontology based semantic model and local data models, which contributes to the flexible information extraction, information integration and knowledge acquisition from heterogeneous, distributed, autonomous information sources. In the next phase of the project, other issues should be considered. Since RM-Grid is a research effort still under active development, we will work on the organization of RM-Grid architecture with the ongoing technology, so as to this architecture could be compatible with the advanced open standards, services and tools.

Keywords: Information Technology Integration Service Platform; DSS; Data Warehouse; Data Mining.

Abstract. Based on the introduction of DSS (Decision Support System) development, the paper discusses the function, structure, key technology and realizing approaches of DSS supported by data warehouse technology according to the characteristic of ceramic information technology service integration platform. Finally, the development direction is prospected.

Introduction

With the application of collaborative management ideology, based on information sharing and collaborative technology, the ceramic information technology service integration platform (CITSIP is called for short) supporting business collaboration of the industrial clusters is researched and developed. The goal of this platform is to provide a scalable, ease using and low cost integrated solution with business collaboration feature for small or medium ceramic enterprises within the region, to improve the capability of independent innovation and business responsiveness, and reduce production costs and enhance the core competitiveness of the whole cluster region. This provides a successful case and demonstration of the regional information service mode and platform operating mechanism for the homogeneous class enterprise clustering area. And the DSS (Decision Support System) is a sub-system of the CITSIP.

Based on the introduction of DSS development, the paper discusses the harmonizing mechanism, function, structure, key technology and realizing methods of DSS supported by data warehouse technology according to the characteristic of CITISP. At last, the development direction is prospected.

Development of DSS

Since DSS's appearing, its development from managing semi-structured problem by using interaction technology to assist managers, to infiltrating computing science, decision science and a variety of AI techniques to the various practical DSS which have appeared, its application involves various areas , and become one of the hot areas of information systems. However, the success examples of the traditional DSS applications are very little. On the one hand the DSS based on traditional DBMS supporting can only provide a data-level support in assisting decision-making process, and the reality data for decision-making is often distributed and heterogeneous; on the other hand the most practical application of DSS have high requirements on decision-makers, who not only need to have professional knowledge but also have a higher DSS modeling knowledge. In order to meet different social needs, a variety of types of DSS is appearing, e.g., intelligent decision support system, distributed decision support system, group decision support system, organizational decision support system [1], adaptive decision support systems [2], strategic decision support system, etc., with the implementation of these systems, each is suitable for different occasions, in different degree to meet the new needs of the decision-making situation.

DSS based on Data Warehouse

Data Warehouse is not a single technology or software, which combines a number of areas, such as database theory, statistics, data visualization and artificial intelligence technology and so on, whose goal is to find a valuable knowledge for supporting decision and predicting the future in the large amounts of data. So the decision support system based on this technology provides a desirable way of data organization for DSS and a powerful decision support tools for decision-makers, and effectively promotes the modernization of decision-making process.

The research and development of DSS based on the theory and technology of data warehouse is still in its infancy[3], but has received the attention of many scholars, Its main research topics includes: ①DW(Data Warehouse) applications in the establishment of DSS, and the structure of DSS based on DW's framework; ② How to enhance knowledge source of DSS by adopting data mining techniques or knowledge discovery methods; ③ Organization and design of DW in DSS and Design of DW's management system. In general, the research of DSS based on DW focuses on how to use DW and related technologies to discover knowledge and how to interpret and express knowledge to users, to provide stronger supporting data of decision support, effectively overcome the difficulties of traditional data management and the issues of ignoring historical data by DSS.

Design and Implementation of Decision Support System for CITISP

The product development of ceramic manufacturers in the ceramic cluster region requires comprehensive, large amounts of information, including the demand information, competitive intelligence, management information, product data, etc., and a lot of information will be obtained from distributed, heterogeneous mass of data by mining, the traditional DBMS cannot meet this need. Therefore, the DSS ceramic cluster region Information service platform based on data warehouse comes into being. Data warehouse system is a subject-oriented, integrated, stable in a certain period, and over time data collection of decision analysis for companies or organizations, which can be carried out to integrate much information from various databases, to organize and store data according to the history and development perspective of things, for users to do data analysis and assist decision support, finally to provide some useful information and knowledge of decision support for decision-makers [4].

A. Design ideas of this system

The DSS based on the data warehouse of platform mainly includes two modules: user information inquiry and fuzzy information inquiry. The module of user information inquiry mainly makes use of text data mining method to search information, according to information provided by the user or enterprise; and in order to facilitate users to quickly find key information needed, the module of fuzzy information inquiry is to simulate the query way of Baidu, search some effective text information, provide available information with a greater match degree to users.

The main design idea of user information inquiry module is shown in Figure 1.

In the design process, using two tables to store related information, respectively, the table "Msg" in the database "AspServer" is used to stored information target data and information word data; enterprise user information is stored in the table "InteractMsg". As known from the design, the information of the table "Msg" comes from network resources, which will be converted into the information used in the module through a series of change. However, the web is a dynamic massive resource, which determines the amount of information resource library is changing with time, and this database used is also dynamically updated. Because of large amount of text information and computing capacity, the time complexity and space complexity will be high in data mining algorithm for mining text, and the processing time of text word segmentation will lag, in the design procedure, if to use directly B/S Architecture for users' communication, the transaction time of the system will be longer, resulting in the situation for waiting the affairs of other users and the performance degradation of the system. Therefore, in order to resolve this problem, an idea of intermediate service is proposed, which is that by making use of segmentation technology the target

data database and enterprise user information technology are converted into the library of information words and the calculation process of implementing matching sets is separated from the system, allowing a stand-alone program “AspServer.exe” to calculate the matching set in advance, so that the performance of this system will be improved.

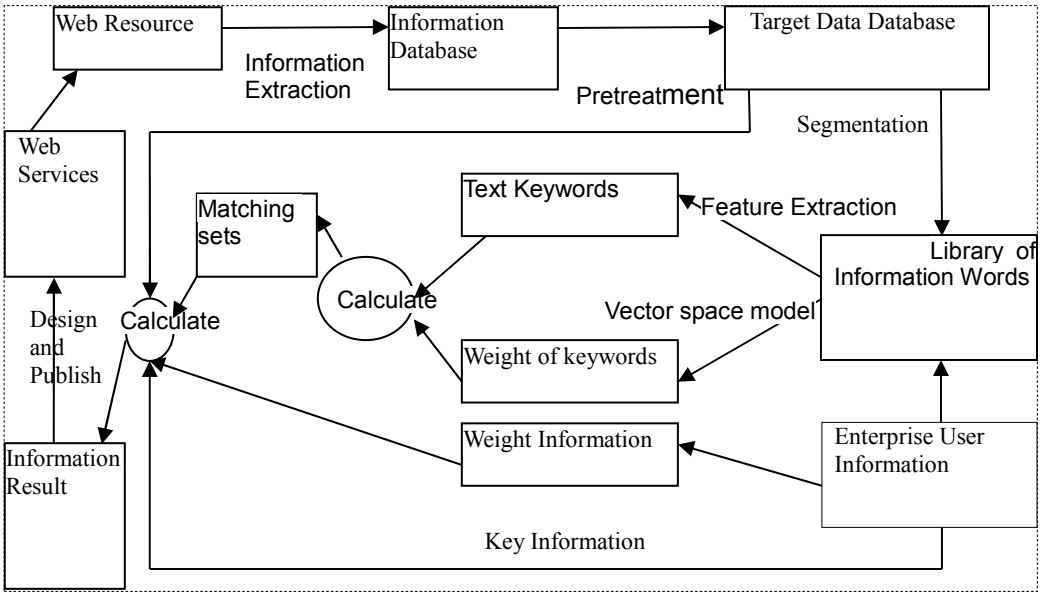

Fig.1. Design idea of user information inquiry

The application is to prevent repeating the calculation processes of matching sets，improve system performance and make some results to be reused. Because of a large amount of data calculation, the procedure in the calculation process will take a lot of CUP and memory, so the system administrator who is implementing the program on the server needs to set a free time to calculate this process, which is the reason for designing this middle service application.

The matching sets obtained by calculating in “AspServer” procedure is stored in the "New" property of table “InteractMsg”. Taking advantage of the property to describe what information extracted is close to the information provided by enterprises (Company Profile) then order them by descending of text message number. For example, the number of the current information are 16, 30, 101, 102, 1976 ,1977, 1980, 1981, 1983, 1988, 1989, 1991, 2001, 2002, 2003, 2006, 2009, 2014, 2017, 2020, 2026, 2033, 2038 and 2052,which are similar with the information submitted by Pengfei Building Ceramic Co., Ltd, other information should be ignored. However, seen from the example, the amount of information is relatively large, as to users’ demand, it is necessary to do further calculating, and make the text messages searched to mostly meet user's requirements.

“AspServer” procedure is to extract information matched in larger degree with enterprise profile; there are still some distances to users’ specific needs. Therefore, more specific information should be provided to further extract relevant information. The decision support system mainly provides some information, such as enterprise products, main material source, other key information and the associated weights, based on this information and the previously extracted information, using relevant algorithm to match with information submitted by users, then order them by descending of information, and finally submit to users.

Fuzzy information inquiry module is designed primarily for users to quickly search some key information. This module also uses word segmentation technology, it can intelligently recognize the information entered by user, then split it into a number of words, according to the frequency and the associated weight of these words in the text message, the importance of text and information submitted is obtained by calculating, then by which to set a threshold level to divide class, e.g. a user submits the information "I love china ceramic", through the segmentation program, two words "china" and "ceramic" are got, making use of fuzzy matching method to calculate the frequency of two words appearing in all text, eventually arranging them according to certain rights of these texts to get the maximum extent of the information related.

If a user submits the information "I love " china ceramic "" ,that means the word “china ceramic” is in quotes, "china ceramic" is only as one word, so there will be three words: china, ceramic, china ceramic. In order to facilitate further search for relevant information in the existing results, the module also provides a function of "search within results", this function is achieved by operation of key words "and", therefore, space can be added behind the keyword existing, then the query keywords should be filled, e.g., "I love china Jiangxi ceramic ".

B. Key technology of implementing system

Data Warehouse Design. The structure design of platform data warehouse needs to arrange reasonably various elements for the goal of decision-making, and ensure the standardization and integrity of the data warehouse system. Definition of various data in data warehouse design is stored in metabase. Data structure of data warehouse commonly makes use of star-shaped model and data model. Firstly it is necessary to define each theme and data source; the data source is divided into internal and external data sources, the properties related with which include a computer platform, data owners, data structure, processing of this data source, storage update plans, etc. Secondly to define the principles of data extracting, refining and loading. Finally, to extend topic, form a theme table and define a data mart.

Data pre-processing. The main task of data pre-processing is to analyze and conduct the data from different platform enterprise database, to identify the inconsistent data used for cleaning, conversion and reprocessing, etc., and then load them into the data warehouse. The concrete method includes two steps: Firstly it is necessary to do extraction, cleansing, standardization, integration for DB1, DB2... DBn data, and convert inconsistent data into consistent data; in this process, a table of mapping name will be created. Secondly, in the process of organizing data from different sources, the data is changed into an intermediate model, and then moved them to a temporary work area. Finally, the inconsistent data is converted into a standard and consistent data, which will be deposited in data area of the data warehouse.

Data Administration. The scale of data warehouse is generally large, at the beginning of establishment, it is necessary to ensure that it should be managed; several data warehouse or data mart may be created in this service platform, which shares a metabase for managing them. First, to inquiry the required metadata element in metabase, and then to do updating operations of the data warehouse, after ending updating operations, the updating situation will be recorded in the metabase. When the operating environment and structure of data source and the maintenance program of the objective data is changing, the metadata is needed to modify. Metadata is an important part of the data warehouse, the quality of which determines the quality of the data warehouse.

Conclusion

The decision support system based on the data warehouse built in this service platform support a variety of knowledge representation and reasoning methods, allow structured data and unstructured data to exist together, various types of distribution, and heterogeneous knowledge sources are integrated for providing various types of effective data for decision-makers to analyze them, which plays a role of supporting decision. Data Warehouse provides an effective and workable system solution for the research and development of decision analysis system. According to a statistic, 98% of top 500 enterprises have established some applications based on the data warehouse, but in our country there is a big gap in this respect. With the growing of China's overall national strength and the rapid development of information technology, more and more successful applications of decision support system will appear. A solution of complete decision support system should integrated data warehouse, OLAP, data mining, and other information processing technology, if this solution is widely adopted, the research and development work of decision support system will be promoted into a higher leveraged on the analysis of the mechanical theory as the foundation, designed the soccer robot pick the ball institutions optimal design process, found aim function, select design variables and the corresponding optimization algorithm to optimize a complete set of institutions, then through the test to get the final performance parameters of the institution. Experiments show that the system has higher accuracy and stability.

[a]e-mail: joson1026@sina.com

Keyword: Campus E-Commerce; MVC; N-layer Framework model

Abstract. Electronic Commerce is now spreading into all sorts of economic activities.Therefore, The E-commerce System call be applied extensively on Campus，aiming at the practical needs of campus business activities．This dissertation ion is going to study the"E—commerce System on campus"based on the project．The system adopts N-layer framework model, realizes its elasticity and expansion and lays a solid foundation for system maintenance and secondary development.

Campus E-Commerce

The development of e-commerce has changed the traditional commercial model. E-commerce itself is equipped with a great advantage and development prospect. In China, developing e-commerce can promote internal reform of enterprises, accelerate information construction of enterprises, improve quality service of enterprises and lay a solid foundation for China to participate in international competition. However, the development of Chinese e-commerce is currently restricted by a variety of factors such as safety certificate, logistics distribution and consumption concept, etc. These problems can be solved to a large extend if e-commerce is developed in university campus.

Campus e-commerce platform refers to a computer system equipped with high availability, elasticity and safety, which is constructed in campus by making use of infrastructure network, computer hardware and software and electronic communication, for the purpose of catering to all the aspects of activity needs of units, enterprises or individuals in campus for handling business, working, studying and living. Relying on campus network, it serves all the teachers and students. In recent years, all walks of life in the society have started construction of e-commerce, and campus e-commerce has also begun to enter the popularization stage. Though construction of Chinese e-commerce has achieved some results, a huge gap still can be seen compared with developed countries. At present, China has not had practical platform of constructing campus e-commerce and even lacked mature campus e-commerce software. Therefore, how to grasp the opportunity brought by global informatization, adopt Internet technology and construct campus e-commerce platform according to characteristics of campus to meet the needs of modern management of campus will be a chance and challenge that educational circles and even the whole world are faced with.

MVC (Model-View-Controller) Framework Model

MVC model is very suitable for software framework with strong interactivity. Campus e-commerce platform is a kind of typical interactive system whose inner core usually keeps stable. For instance, its model of domain data (such as order and commodity) is often unchanged, but the interface of data used for observation is changeable. For example, with regard to checking order data, ordinary users want to check their own orders and see which goods are delivered while clients opening shops would rather check some statistical data of their orders. Under the circumstances, though users see different external forms, actually their internal data models are consistent. MVC framework model can provide such interactive system with a basic structured organization.

The full name of MVC is Model-View-Controller, namely model-view-controller framework mode. The model divides an interactive application system into three layers:

Model Layer: It encapsulates domain data and informative function. Independent of given output representation and input mode, model is an invisible object which includes all the data and conducts except for the data and conducts of UI and belongs to an object of domain model.

View Layer: It is responsible for demonstrating information to users mainly through interfaces. View obtains data from models. A model consists of many views.

Control Layer: Controllers usually accept user input and are usually taken as the activities of mouse move and mouse button or events of keyboard input. The event is translated into the server request of models or views. Users only interact with system via the controller. Each view invokes the corresponding controller and completes displayed data input. Views take charge of display output function of data. They together constitute the interface of users.

The relationship of the three is as shown in Figure 1:

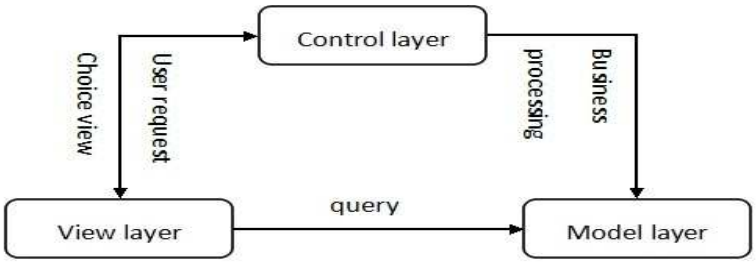

Figure 1:MVC model

It is because of separation of models, views and controller components that realize a model and many views. If users change models through the controller of a view, other views relying on the data can also reflect such change. In other words, once data of models changes, models will report to all the views. In reverse, views recover new data from models and update the information displayed.

The advantages of MVC design mode:

Allow expansion of many user interfaces: In MVC model, views and models do not have necessary connection and interact with each other via controllers. In this way, changing corresponding views and controllers instead of models can add new type of user interfaces.

Effectiveness of modules: Program change of controllers, models and views will not influence other layers and components. Additionally, different component development can occur simultaneously.

Reusability of code and design: Extensively adopting reusable components can make communication among development teams convenient and system designed easy to understand and reduce development cost of projects.

Ease of maintenance: Controllers and views can accordingly expand following expansion of models. Keeping a common interface, old version of controllers and views can also be used continuously.

Strong user interfaces: Invocation and combination of user interfaces and model methods enable program to release more clearly and friendly interfaces to users.

In conclusion, MVC is a good design mode of constructing application framework, which can separate business process from display, divide application into controllers, models and views and increase expansibility, robustness and flexibility of application.

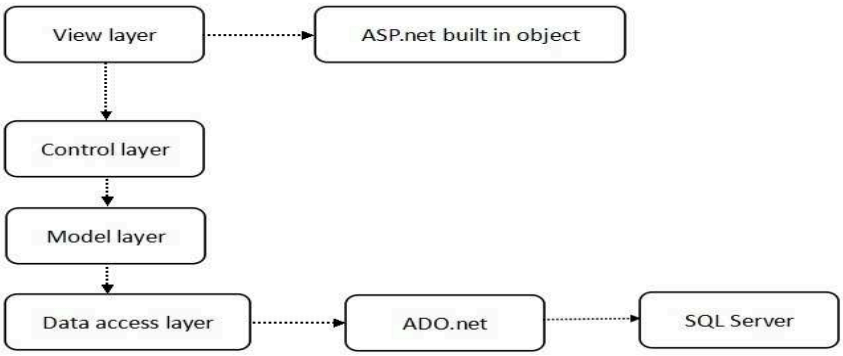

Figure 2： Model Framework of Campus E-Commerce Platform

Model Framework of Campus E-Commerce Platform Based on MVC

Campus e-commerce software system framework diagram is as shown in Figure 2, which combines the characteristics of campus e-commerce system, adopts advantages of layer model, designs and realizes campus e-commerce platform software framework and puts forward soft framework schemes. The framework takes advantage of MVC model to design four-layer framework. The top layer is view layer which mainly displays data, acts as the interface through which software users make contact with software, deals with layout by using elements like HTML and CSS and captures and presents event response of user operation by means of Asp.net object and JavaScript. Event handling achieves its goal through invoking business logic function of the controller layer which provides the interface of invoking business logic and realizes separation of display and logic. In addition, the controller layer provides lower layers with the interface of handling business logic. The interface is just abstract statement and is realized through data access. Data access layer meets the needs of data access aimed at specific database platform. The system realizes operation of SQL-Server database through ADO.NET interface, which returns data to padding model layer. The domain models of the system layer are commodity, order and users. Domain model is the projection of data entity of database. In every layer, there is internal system structure. The specific description of collaboration diagram of various components of campus e-commerce software system is as shown in Figure 3.

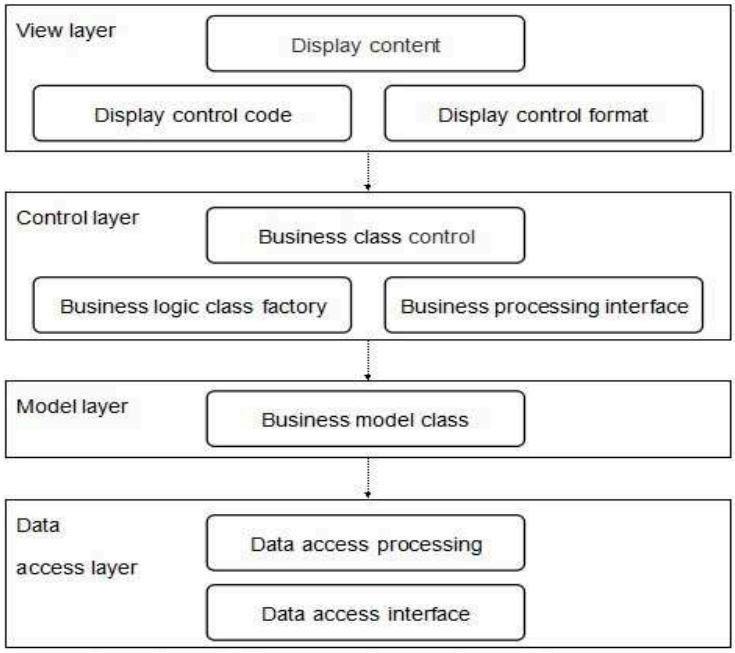

Figure 3: Campus E-Commerce Platform Component relationship

View Layer

It is actually class package of interfaces of system. It plays a role in setting up the interface used by user window of the system and supporting system. The layer is made up of three aspects including displaying format control, user content pages and control codes.

Display format control package: It mainly controls various page formats and sets up page layout to control display modes of interfaces and display styles of webpage.

Display content pane: It is mainly responsible of setting of webpage content and sequence and is taken as the main part of webpage display.

Display control interface: It mainly makes use of models separated by means of code of net platform to control dynamic display of page contents.

The layer separates format, content and control so as to make system easy to maintain, expand and control.

Control Layer

In fact, it is the domain logic layer of business object of system, connects pages and the interface of realizing specific functional service of system and provides functional service of system through

managing business object of system. It is composed of three parts including commercial control logic function, commercial logic class factory and business process interface.

Business logic control: It directly offers domain service of system and plays a transitional part in connecting setting pages and various interfaces of realizing specific functional service.

Business logic processing interface: It provides an abstract interface for invocation of commercial logic. It is usually functional class inheritance of specific system business. The type of object realizes database operation and actually processes specific and practical business.

Actual business logic object package: Its formation can realize actual business object set of various functions of system including business object and external business object newly constructed by system.

Business logic class factory: It realizes dynamic creation of actual business object.

The layer provides the upper layers with a unified interface for invocation and the lower layers with a unified interface for realization. Such design makes the interfaces stable, lessens range of fluctuation of system and facilitates its maintenance.

Model Layer

As the projection of database table, the layer mainly realizes data storage of business class object, provides a container for managing the class object and data support of business logic based on the business model.

Data Access Layer

Closely related to specific database, the layer provides specific operation and access methods of database. Here, it invokes the interface of ADO.NET and realizes persistent object access to database of SQL-Server.

All the persistent data of the system is stored in database

Conclusion

Electronic Commerce is now spreading into all sorts of economic activities. Therefore, The E-commerce System call be applied extensively on Campus, aiming at the practical needs of campus business activities. Campus e-commerce platform takes all the teachers and students as the main customer base, construct e-commerce platform as per their needs and determine transaction contents and forms. The system adopts N-layer framework model, realizes its elasticity and expansion and lays a solid foundation for system maintenance and secondary development.

The Study on the Improvement of Observer Pattern based on .net Framework

Zhenjun Fan

College of Computer Science, Tonghua Normal University, Tonghua, 134002, China

email:jlthfjq@163.com

Keywords: Object-oriented Programming; Observer Pattern; Delegate; Event

Abstract. This paper introduces the relevant concept of observer pattern and realized method. Based on .net framework, we make detailed discussion about the principle and method of observer pattern, which is simplified and improved by delegate and event mechanism.

Introduction of Observer Pattern

A design pattern is a set of objects. The main function of design pattern is to solve a kind of special problem and it is the optimal method to solve the problem [1]. Software will have excellent reliability, expandability, reusability and maintainability using design pattern. Design pattern is a summary of experience of designing and developing software, a sort of expert knowledge.

Definition of Observer Pattern

Observer pattern is a classical design pattern. It defined a dependency relationship from one to many among objects. All dependency objects will be noticed and automatic updated when an object alter its state [2], where the dependency objects are called observers, and another one is named subject. Observer pattern allows many observers to monitor the same subject. All observers will be noticed and responded when the subject changes. The relationship between observers and subject is loose coupling. Subject can increase and decrease observers at any time and it cannot be affected. Observer pattern aims at decreasing the degree of coupling among components and decreasing dependency relationship among objects.

Roles in observer pattern

There are four roles in observer pattern [3].

Abstract subject role:

Subject role preserves all citation of observer objects into an accumulation, and every subject can own any quantity of observers. Abstract subject provides an interface which can increase or delete observer object. Subject role is also named abstract observable role; generally, it is realized by an abstract class or an interface.

Abstract observer role:

It defines an interface for all specific observers and it will be updated when it is noticed by subject. This interface is called updated interface. In general, abstract observer role is realized by an abstract class or an interface. Only one method is performed to update interface and this method is called updated method.

Concrete subject role:

All registered observers are informed when internal state of the concrete subject changes. In addition, concrete subject is also called concrete observable and it is realized by a specific subclass.

Concrete observer role:

It realizes the update of interface asked by abstract observer role to guarantee that the state of observer is coordinated with the state of subject. Concrete observer is normally achieved by a concrete subclass.

Main operation of observer pattern

Three kinds of operations are included in observer pattern, i.e. register, notice and cancel.

Register:

Observer calls the registration method of subject, so that it can be registered in the subject.

Notice:

Subject sends messages to inform the data changing for all registered observers when the state of subject alters.

Cancel：

Observers will cancel the subject if it does not need to observe the subject, so the observation of subject is cancelled.

Universal implementation method of observer pattern

Traditional implementation method

Interface is generally adopted traditionally. Class is regarded as observers or subject role through realizing corresponding interface. Abstract observer class provides the updating method which is coordinated with the data changing of subject. All observer demand realizing such interface to correspond the changing behavior of subject. Subject interface provides three methods to perform registering, cancellation and notice to all observers. Subject class must realize these methods.

Analysis of traditional implementation method

We know that concrete subject is realized by subject class from traditional implementation method. A private Hash table object is involved and it is a container to store observer objects. Observers are added to Hash table using register method, the relationship between observers and subject are cancelled using Un-Register method. There is a method to notify observer the corresponding data changing when the state of subject changes. Each observer object must inherit observer interface, which is inflexible and inconvenient. It is necessary to create a new method when developers hope to realize observer, but the interface isn't realized, or the realized interface is incorrect. Subject should preserve list of observer to realize registration, cancellation etc., so, there are undirected relationship between subject and observer. It is time-consuming to inform all observers if an Subject object own many directed and undirected observers, for all list of observer has to be searched through as a loop, so the efficiency is determined by the scale of observer list.

Realizing observer pattern using delegate and event mechanism in .net program

For the purpose of realizing low coupling, we can take advantage of delegate and event technology to realize observer pattern [4].

Delegate

Delegate is a class. It defined the type of a method and passed a method as parameters of another method. This kind of dynamic parameter can avoid using many selected statement, so the program has better expandability [5].

Delegate may not know detailed information on the class of capsulation method. This method can be called as long as the parameter types and return type match delegate. We can make full use of the important property of delegate and event mechanism to complete observer pattern. Thus, coupling among objects is decreased, and static combinational relationship is altered to dynamic one. The other significant property of delegate is multicast, which can help realizing registration and cancellation of observers.

Event

Event is further capsulation of delegate in .net framework. Event can be easily grouped into two parts: the class of event occurring and the class of event processing [6].The class of event occurring is to trigger an event in this class but the class doesn't know which object or method will receive and handle the event. The class of event occurring is treated as observable, and the class of event processing is regarded as observer. Sender and receiver accomplish the event processing through delegate.

Realizing observer pattern using delegate and event mechanism

Subject class doesn't need to realize any interface or inherit from abstract class，an agency and an event is only needed to provide when .net application program adopts agency and event to realize observer pattern. For observer class, it only needs to provide an updating method [7].

In the process of using delegate and event mechanism, observer establishes an agency, then, it passes the name of updating method to the agency and registers this agency to the event of subject class.

The improvement of observer pattern based on .net technology

There are no linked list and traversal operation in these codes using .net framework technology. Subject class and observers do not require any interface. Subject class provides an agency and an event to send data updating information to every observer object. It can simply add new different observer objects even though it does not know where these observer objects inherit from and doesn't need to unify their interface method. Observer class only realizes updating method corresponding to the changing of subject and registers this method to the event provided by subject class. Observers can employ "-=" operation to cancel when they do not need observing the changing of subject class. Traditional observer method realized by interface can decrease coupling between observer and observer object, while agency and event almost remove coupling between these two modules. So, flexibility is enhanced.

Conclusions

Registration, cancellation and notice in observer pattern can be performed by dynamic combination between delegate and event mechanism based on .net framework. Thus, it unchains dependence of goal object on observer, and decrease the coupling of them, so flexibility of design is enhanced.

Design and Implementation of an Intelligent Cross-Platform IaaS

Fen GUO [1, a], Qing DU[2, b], Jie YANG[3, c]

[1, 2, 3] School of Software Engineering, South China University of Technology, Guangzhou, 510006, China

[a]email: csguofen@scut.edu.cn, [b]email:duqing@scut.edu.cn, [c]email:yjclear@scut.edu.cn

Keywords: Cloud Computing; Virtualization; IaaS

Abstract. Cloud computing is considered to be the next generation of IT service model, and the virtualization technology is the key technology of it.The paper focuses on the design and implementation of an intelligent cross-platform IaaS platform which is called ICIaaS. It is based on the existing open source platform technology, while its deploying and scheduling strategy for virtual machines (VMs) is self-owned. The ICIaaS is compatible with the current mainstream commercial VM, and has applied in the current research project. It is concluded that it has achieved heterogeneous virtualized computing platform integration and intelligent VM management strategy.

Introduction

Cloud computing [1] is considered to be the next generation of IT service model, which has got a lot of attention from academia and industry. Virtualization technology is one of the key technologies of cloud computing, and it has greatly improved the utilization of computing resources, reduced the physical infrastructure, and implemented the on-demand deployment. Infrastructure as a service (IaaS) is an important branch of service delivery model of cloud computing. Various virtualization vendors have various independent management platforms. The different management way has brought great inconvenience for the application of IaaS. What's more, most VM deploying and scheduling strategy is too simple to meet the real-time requirements.

Most designs of the IaaS have been emphasized with the merchant's profits but the research value. Studies of these effects covered various aspects, and the subject is concerned chiefly with the design and implementation of an intelligent cross-platform IaaS (Infrastructure as a service) platform which is named as ICIaaS. It is based on the existing open source platform technology.

This paper is divided into four major sections as follows. Section 1 opens with the design architecture of the ICIaaS. Section 2 shows the self-owned virtual resource scheduling strategy. Section 3 provides the implementation and application of the ICIaaS, and section 4 draws a conclusion.

Design Architecture

The main goal of ICIaaS is to achieve heterogeneous virtualized computing platform integration and intelligent VM management strategy, so as to meet the needs of laboratory teaching and research and promote the combination of intelligent computing and cloud computing.

The ICIaaS invoked various virtualized computing resources through the API.It used a new IP address assignment technology basing on VM images injection[2], which has improved the polling host distribution[3] method. The user can use the underlying computing resources with the Web management end, and the platform is compatible with the current mainstream types of VM.

The mail goal of the intelligent VM management strategy is: to choose the most appropriate scheduling policies dynamically to deploy VM according to user requirements and the real-time monitoring data. And a new load balance deployment strategy is developed.

As in figure 1, the ICIaaS consists of three layers as follows.

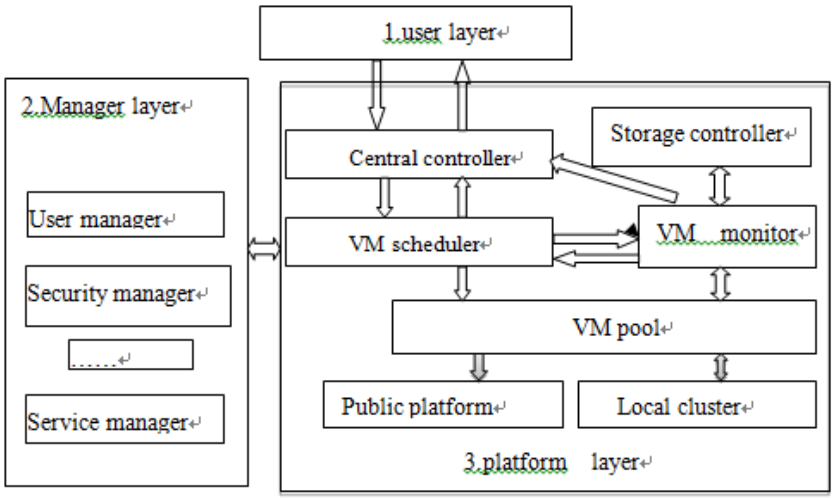

Fig. 1 The architecture of ICIaaS

1) The user layer: It is the interface that the user can interact with the ICIaaS conveniently.
2) The manager layer: It includes service management, user management, security management, etc. For example, the user manager is in charge of user information and rights .The service manager modules provide the service components which encapsulate services and functions of the underlying, and users can customize the service according to the needs on the Web interface.
3) The platform layer: It includes Central controller, memory controller, the VM scheduler, and the VM monitor, etc. The details are as follows.
   a) Central controller: It is composed of a set of services which coordinate the whole intelligent system. These services will response all the user requests ,validate and maintain system and user metadata .It employs the main standby server hot backup mode to ensure the security, which does not need to stop the system when failure appears.
   b) VM scheduler: It will deploy and schedule the VMs dynamically by analyzing the real-time data from the monitor. It has the function of static distribution and dynamic allocation. The details are in section 3.
   c) VM monitor: This module is in charge of monitoring the real-time usage of the service and resource, and then offers the reference to the scheduler. In order to generate resource allocation proposal, the monitor should summarize and analyze the surveillance data. It provides the user layer with a report, which will be helpful for the further task optimization.
   d) Storage controller: It is responsible for cloud storage management, including storage application, recovery of free space, access control, etc.
   e) Virtual resource pool: It encapsulates different kinds of VM. The module integrates local private cloud and public cloud. Firstly, it selects a virtualization platform type automatically. Secondly, it creates a VM by invoking the corresponding public API of various open source platform or private function provided by ICIaaS.

Resource Scheduling Strategy

The VM deploying and scheduling strategy is composed of the static and dynamic parts. The ICIaaS selected the BFD [4] strategy as the static one, and designed an intelligent deployment optimal selection and dynamic VM migration strategy as the other one. The process of the Strategy is noted in figure 2. The details are as follows: Firstly, to choose the best appropriate strategy, combining with the user demand and the current load value of the ICIaaS. Secondly, to choose the appropriate VMs to be migrated to rearrange the current request when there is no host to meet the requirement on the current scheduling domain.

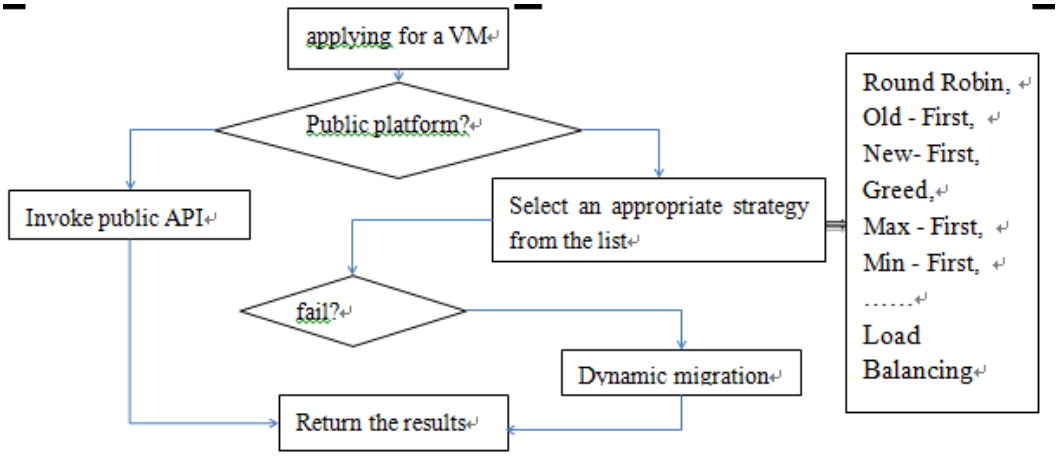

Fig. 2. The process of the strategy

1. Mathematical Describing

The objective of the strategy is as follows: (1) to meet the existing load request, and maximize the load balancing on each physical server scheduling domain. (2)to minimize the number of hosts to start on ICIaaS on the basis of 2.(3)to control the load rate of all hosts in each scheduling domain not higher than the specified threshold system.

Let $bl(j)(j \in [1,m]$(m stands for the number of the hosts in the scheduling domain) be the load performance value of the host p_j, O as the load performance value of the scheduling domain. Function f returns the number of the VMs deployed on the host p_j, while $H_p(P_j)$ represents the performance value of host p_j ,and $H_v(j,i)$ stands for the performance value of the VM V_{ji} . $\overline{W_x}$ (X can be a VM or a host) represents the performance weight vector, while $\overline{S_x}$ stands for the real-time performance vector. The performance weighted strategy calculates the load performance according to the following formulas.

$$H(x) = \overline{W_x} \times \overline{S_x} \quad (1)$$

$$bl(j) = \sigma \times H_p(p_j) + (1-\sigma) \times \sum_{i=1}^{f_n(j)} H_v(j,i)/f_n(j) \quad (2)$$

$$O = \sqrt{\sum_{j=1}^{m}(bl(j) - |bl|)^2}/m \quad (3)$$

2. Algorithm

If (m> threshold number)
return the first j in $\{j|j \in min_{j\in[1,l]} \Delta bl(j)\}$
else return the first j in $\{j|j \in min_{j\in[1,l]} \Delta O(j)\}$

The $\Delta bl(j)$ stands for the predicted change value of the load balancing performance of host p_j if the new VM is deployed on p_j.And the $\Delta O(j)$ stands for the predicted change value of the load balancing performance of the current scheduling platform.

Implementation and Application

The ICIaaS is compatible with the current mainstream commercial VM such as KVM[5], XEN[6], and has applied in the current research project.

1) Server virtualization: The basic part (such as VM application, destroy, etc.)adopts a mature virtualization management – libvirt, the advanced part (such as a balloon native memory drift technology) is developed by C language.
2) Network virtualization: It uses fixed IP allocation mechanism basing on the libguestfs VM images injected technology.
3) User's Web interface: The Central controller provides command interface for Web interface, so user can interact with it. The Central controller will check the legitimacy of

the command and parameter after accepting commands, and then return the results to the Web interface.

Conclusion

The research we have done suggests an increase in the VM deploying and scheduling strategy and various IaaS integration, which achieves the Qos and the good performance of cloud to some degree. The ICIaaS did provide a module of IaaS,which took the customer requests and the weight of performance parameters into account. What's more, it unified the virtualization resources view.We will improve the dynamic migration strategy to the platform to enhance the system reliability in the future work.

A network information filtering method based on node energy transfer

Ji LIU

Institute of statistics and information, Xinjiang university of finance and economics, Urumqi, china, 830012

email: liuji5000@126.com

Keywords: network information filtering; overlapping node; redundant recommendation energy; nonnegative matrix

Abstract. Network information filtering can be projected into link prediction in bipartite network to alleviate information overload. The paper discovers that node transfers redundant recommendation energy in network and gives bad effect on information filtering efficiency. Gathering node's overlapping degree by factorizing negative matrix, redundant energy is reduced with overlapping degree and initial recommendation energy. The method endows information filtering system with dynamic recommendation prediction, the empirical results indicates the method can enhance information filtering performance.

Introduction

The amount of information increases far more quickly than our ability to process it. Information filtering technology came into being as an effective method to alleviate the problem of "information overload"[0]. LIU mei-lian0 proposed a scheme of combining the shopping preferences of consumers and network behavior information to make information filtering. YUAN xiao-fang0 combined case-based reasoning and ontological structure to enhance the information filtering quality. With development of social networks, users can not only create information nodes, but also change the network links between them. Netizens' activities would have impact on information filtering results for others. ZHOU tao[4,5,6] projected information filtering system into user-object bipartite network and proposed information filtering algorithm based on network structure.LIU jian-guo[7][8] improved the computing similarity based on character of node . Some other researchers filtered information according to behaviors of online netizens0,the sparsity of recommendation data with tagged network[0]is reduced and revising the method of resource allocation[0] is revised. As a result, the quality of recommendation is partially improved. ZHANG Chu-xu0 combined rating information of netizens and clustering information of netizens, refining information of collaborative filtering commendation . Considering the effect of time window on reducing the complexity of information filtering computation and storing data, GUO qiang0 presented recommendation method based on time window. Although the above methods improved information filtering quality based on diffusion kinetics of netizen behaviors, the recommendation energy is amplified in the information filtering network .In addition, the recommendation energy of node is not stay at a static value with time, how to depict the transfer of recommendation energy in network is new problem facing us.

Resource allocation in bipartite network

Users and resource objects construct selecting (rating) relationship network in information filtering system, meanwhile, recommendation energy of objects can allocate and flow on network. The main target of information filtering system is providing new resource object for user based on users' information of selected resource object. Information filtering system can be projected in bipartite network is composed of users and objects, and the task of the recommender system is to provide new objects for user based on historical information of collecting. The object-set can be denoted as $O=\{o_1,o_2,o_3,\ldots o_n\}$,and user-set as $U=\{u_1,u_2,u_3\ldots u_m\}$, So we can get a $m\times n$ matrix $A=\{a_{ij}\}$,where $a_{ij}=1$ if u_i collected o_j, and $a_{ij}=0$ otherwise. Typically, bipartite network can be set as

G(X,Y,E), E denotes set of edge, X,Y can be denoted as $\{x_1,x_2,x_3,\ldots x_n\},\{y_1,y_2,y_3,\ldots y_m\}$,X's i-th node 's initial resource energy is $f(x_i)\geq 0$.

Tao Zhou[0] presented a weighted resource-allocation network to describe the relation of different resource. We can use the method to compute the allocation relation between objects in information filtering system. In the first stage, we can compute the recommendation energy of objects collected by user with edge in user-object network, In the second stage, user allocates he or her own energy to different objects, $f'(o_i)$ denotes the cumulated energy of o_i from all objects at last

$$f'(o_i)=\sum_{l=1}^{m}a_{il}f(u_l)/k(u_l)=\sum_{l=1}^{m}\frac{a_{il}}{k(u_l)}\sum_{j=1}^{n}\frac{a_{jl}f(o_j)}{k(o_j)} \tag{1}$$

Then ,we can draw,
$$f'(o_i)=\sum_{l=1}^{n}w_{ij}f(o_j) \tag{2}$$

where
$$w_{ij}=\sum_{l=1}^{m}\frac{a_{il}a_{jl}}{k(o_j)k(u_l)} \tag{3}$$

The weight denotes the degree of resource object o_j allocated to o_i, based on this weight and the initial recommendation energy of object that user collected, we can predict the final energy of each object by

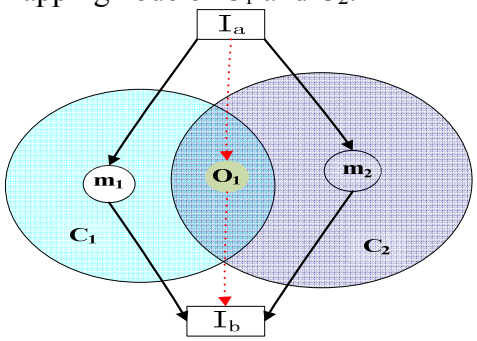
$$\vec{f}'=W\vec{f}\ . \tag{4}$$

The top N objects can be obtained by sorting final recommendation energy in descending order, and we can recommend those N objects to active user.

The reduction of recommendation energy transfer in network

Resource allocation method allocates recommendation energy on network by transferring nodes twice, and draws transferring weight of recommendation energy between different resource objects, the matrix weight is denoted as W in eq.3. Since some resource objects are similar while some users are also resemble ,there is some redundant energy that transferred from similar objects(see[6]). The ability of transferring recommendation energy of node depends on the location of node in communities, we can see in graph 1.

From graph 1,we can see that m_1 is a core node in the community c_1,while m_2 also is a core node in the community c_2,$o_1$is an overlapping node of C_1 and C_2.



Graph.1 The transfer of recommendation energy in network community

The ability of transfer energy of Node m_1 and node m_2 is low. As an overlapping node, the node o_1's ability of transfer redundant recommendation energy between I_a and I_b is bigger than node m_1 and m_2.If we can get overlapping degree of node ,we can reduce the redundant recommendation energy in transfer process partially.

Computing overlapping degree of network node

The matrix that made up of user and object is a large scale non-negative matrix. We can use matrix factorization to reducing dimension of matrix and study character of overlapping node . see[14] . NMF can be looked as optimal problem.

$$E = \|V - QH\|^2 = \sum_{ij} (V_{ij} - QH_{ij})^2 \tag{5}$$

Lee[14] proposed a new update algorithm, the update rule is:

$$H_{au} \leftarrow H_{au} \frac{(Q^T V)_{au}}{(Q^T Q H)_{au}} \qquad Q_{ia} \leftarrow Q_{ia} \frac{(V H^T)_{ia}}{(Q H H^T)_{ia}}$$

Here if h_{ij} is the largest element in column j，the object j probably belongs to community i. If the second largest correlation value is similar to the largest ones, the node is probably overlapping node . we define overlapping degree as：

$$od_j = \frac{h_j^{**}}{h_j^{*}} \qquad ODM_{ik} = \begin{cases} 0, i \neq k \\ od_i, i = k \end{cases}$$

H* denotes the biggest correlation value in column j, while h** is the second largest correlation value in column j. The bigger overlapping degree value a node has, The bigger redundant energy the node transfers. The overlapping degree of all nodes can be set as overlapping degree matrix(ODM).

The reduction of recommendation energy transfer

Because some redundant recommendation energy can be transferred by overlapping node,we can use overlapping degree to reduce redundant recommendation energy(RRRE), the original weight matrix can be update as:

$$WED = W - W \times ODM \times W \tag{6}$$

For a given u_l, the different initial configuration will process on the network. In general, recent collecting activity can reflect a user's current preference accurately, the recommendation energy of node will decay with time .If the current time is t, the energy of initial configuration for u_p is

$$f^{t}_{u_p, o_j} = e^{\left[-\gamma \frac{(t - t_{u_p, o_j})}{\max_n (t_{u_p, o_n}) - \min_n (t_{u_p, o_n})} \right]} \tag{7}$$

γ is time attenuation coefficient of initial object. In this paper we set it as $\ln[\max_n(t_{up,on}) - \min_n(t_{up,on})]$,From above equation, the energy of resource objects in uncollected set is

$$\tilde{f}^{t}_{u_p, o_i} = \sum_j wed_{i,j} \times f^{t}_{u_p, o_j} \tag{8}$$

The top N resource objects can be obtained by descending energy of recommendation and be recommended to target user.

Empirical result

In order to test the accuracy of algorithm, we use MovieLens as benchmark data sets. The data set 1 consists of 10^5 ratings for 1682 movies by 943 users, the data set 2 consists of approximately 10^6 ratings for 3952 movies by 6040 users. We divided each data set into two parts based on rating time, which can be distinguished by the timestamp of the movieLens data. Typically, as for the two different data sets, we selected 30% records for each user that occurred in recent time as testing data, others 70% as training data.

For a given length L, the prediction list of user ul contains L objects. For each pair of relationship between a user u_l and objects on the list, o_j item in testing data，if o_j is also in the prediction list of u_l, we say the pair of user–object be hit in the given prediction list by system. The ratio of hit entries to the length of L is called the "hitting rate". Generally, for a given L, the algorithm with higher hitting rates is better prediction algorithm.

Table 1. The hitting rates for some typical lengths of prediction list.

Dataset	Length	GRM	CF	NBI	RRRE
Data set1	**10**	4.74%	6.26%	5.93%	8.11%
	50	16.78%	21.02%	21.45%	26.95%
	100	27.55%	32.72%	33.85%	41.68%
Data set2	**10**	2.98%	3.33%	3.40%	3.93%
	50	11.19%	12.38%	12.77%	15.11%
	100	18.74%	20.84%	21.61%	25.39%

The hitting rates of some typical lengths of prediction list are shown in table 1. When the length of list is 10，the merit of RRRE(reduce redundant recommendation energy) is obvious. The accuracy of information filtering is promoted by 70.25% higher than GRM(Global Ranking Method), and 28.91% than CF(collaborative filtering), and 31.65% than NBI(network-based inference) in dataset1, while promoted by 36.24% higher than GRM, and 21.92% than CF, and 19.41% than NBI in dataset2.

Conclusion

Based on network energy transfer, the paper proposes information filtering method recommends resource objects for users in dynamic environment. The redundant energy of recommendation has much business with the node overlapping degree. With a non-negative matrix factorization method, we get the overlapping degree and reduce the redundant recommended energy transfer and reduce initial energy of different objects according to time. Experimental data show that this method results in hit rate is better than other traditional methods.

[a]wjw0331@163.com, [b]sunwenyi@126.com

Keywords: Wireless sensor networks; HEED; Trust routing; QoS; energy efficient.

Abstract. In Wireless Sensor Networks (WSNs), besides the energy efficient, trust and Quality of Service (QoS) supported should be considered under some circumstances. All of them unveil additional challenges for routing scheme design. Based on Hybrid Energy - Efficient Distributed clustering (HEED) protocol, this paper presents a trust QoS routing algorithm for WSNs. Hierarchical structure is adopted and the trust value of the node is constructed by the direct trust value and the indirect trust value. In HEED, the combination of the trust value and residual energy as the main parameter and the propagation delay as the secondary parameter. The former guarantees the credibility of the data transmission, and the latter ensures the load balance of the entire network. Compared to typical routing algorithms of sensor networks, the proposed algorithm has better performance.

Introduction

Wireless Sensor Networks (WSNs) have got more and more attentions by people. However, WSNs are often placed in hostile environments and operated on an unattended mode in order to cooperatively monitor physical or environmental conditions. Due to the Characteristics of restricted by the limited resources of sensor node, WSNs can only support inherently unreliable communication [1]. Moreover, under some circumstances, nodes may suffer from malicious attacks such as denial of service (DoS) or packet modifications. Hence, the trustworthiness of routing information is an additional important parameter of it.

However, the existing routing protocols always pay more attention to energy efficient and Quality of Service (QoS), they rarely take the credibility into account. Providing trust guarantees in WSNs is a very challenging problem, but several approaches have been proposed in the literature. Related literature can be found in paper [1]-[3]. However, all of them cannot scale large networks due to the computation of trust value and no QoS parameters are considered.

Trust QoS Routing Model

WSNs can be modeled as a connected, undirected and weighted graph $G(V,E)$, where V denotes the set of nodes (sensor nodes and sink node) and E depicts the set of bi-directional links between nodes. For a pair of nodes $v_i, v_j \in V$ if the link $e_{ij} \in E$, then (v_i, v_j) are treated as a pair of adjacent nodes. Each node $i \in V$ in the graph, includes a set of three QoS metrics elements: $\{dl(i), re(i), tr(i)\}$. Where $dl(i)$ expresses the queuing delay, which can be obtained by the distance between two nodes, $re(i) = E_{res}(i) / E_{init}(i)$ denotes the remaining energy with respect to the initial energy and $tr(i)$ indicates the trust value.

Trust evaluation mechanism. Trust value of network nodes consists of direct trust value and indirect trust value. Direct trust value is determined by the node status and routing behavior, indirect trust value is determined by the interactions with the neighbor nodes.

Direct trust value. For the *n* recent historical records of a node, a triple $< td_i, time_i, td_m_i >$ is stored. Here, td_i refers to the initial trust value, $time_i$ refers to the time of inserting behavior,

td_m_i refers to the modified trust value. Set effective time window, the behavior record over the effective time will be removed from the window. Trust nodes using information of the recent behavior to take trust evaluation. Each behavior trust value of the record $td_i \in [0,1]$.

Computing trust value of node *i* in the recent period:

$$T_dir_i = \begin{cases} \sum_{i=N-n}^{n} \frac{time_i - time_{N-n}}{\sum_{i=N-n}^{n} (time_i - time_{N-n})} * td_i & n \neq 0 \\ 0 & n = 0 \end{cases} \quad (1)$$

Indirect trust value. The trust values of neighbor nodes to the evaluated node are used to calculate the indirect trust value. Any neighbor nodes of the trusted node *i* calculate its trust value t_ind_i recommended by the trust node:

$$t_ind_i = \begin{cases} r_i & td_i \geq \beta \\ td_i * r_i & 0 < td_i < \beta \\ 0 & td_i \leq 0 \end{cases} \quad (2)$$

td_i refers to the trust value of the neighbor nodes of the trusted nodes, r_i refers to the direct trust value of the neighbor nodes of the trusted nodes to the trusted nodes, β refers to the trust threshold. Indirect trust value defined as the mean value of all neighbor nodes to the trusted node:

$$T_ind_i = \frac{\sum_{i=1}^{n} t_ind_i}{n} \quad (3)$$

n refers to the number of neighbor nodes of the trusted nodes.

Comprehensive trust value. Comprehensive trust value reflects the trust of the node to the trusted node, consists of direct trust value and indirect trust value, calculated as follows:

$$tr(i) = (1 - \frac{init_n}{N}) * T_dir + \frac{init_n}{N} * T_ind \quad (4)$$

$init_n$ refers to the number of initial behavior records in a sliding window.

Delay Estimation. Wireless sensor nodes are scattered over a two-dimensional plane following a uniform distribution. Assume energy consumption follows free space model [4], then:

$$r = \frac{\lambda \sqrt{P_t / P_r}}{4\pi} \quad (5)$$

Here, P_r is received power of destination node, P_t is transmit power of source node, λ is the wavelength of signal, r is the distance between the two nodes.

Then the propagation delay between the two nodes is:

$$dl_{tr}(i) = r / c = \frac{\sqrt{P_t / p_r}}{4\pi f} \quad (6)$$

Here, f is the frequency of electromagnetic wave.

Because TDMA strategy is used to packet transmit, there is no queue delay in the procedure. Then the data processing delay $dl_{dp}(i)$ is fixed and depends on the node processor and packet length. The delay of the path is constructed by two parts: from general node to cluster head node $dl(s)$ and from cluster head node to base station $dl(b)$.

$$dl(P) = dl(s) + dl(b) \quad (7)$$

Algorithm Description

3.1 Cluster Head Node Selection

Hybrid Energy - Efficient Distributed clustering (HEED) [5] protocol is proposed in 2004. In order to prolong the network lifetime, it periodically selects cluster heads according to a hybrid of a main parameter (such as residual energy) and a secondary parameter (such as intra-cluster communication cost). The modified expression of main parameter is:

$$P(i) = \alpha tr(i) + \beta re(i) \tag{8}$$

Here, $P(i)$ is the probability of the node i being chosen as a cluster head node, α, β are weighted factors and $\alpha + \beta = 1$. The node which possesses more trust value and more residual energy will have more probability to become a cluster head temporarily.

3.2 Clustering Process

Once the cluster head nodes are selected, each of them will send a broadcast package to the other nodes along with the delay information $dl(s)$. In the proposed algorithm, the transmission delay from the regular node to the base station $dl(P)$ is chosen as the secondary parameter. If a node can't receive any of the broadcast information, then it is forced to become a cluster head nodes. If a node may receive more than one of the broadcast information, according to the received $dl(s)$, the node computes the path delay $dl(P)$. Under the premise of meeting delay requirement, the node decides to join the cluster through the trust value.

3.3 Packet Transmission

After the period of clustering process, the cluster head node adopts TDMA strategy to assigned time slot to the other node inside the cluster. The other node can send packet just in their respective slot, and in the rest of time, it is in the sleep state to reduce energy consumption. In order to ensure credibility of packer transmission, CRC check mechanism is used. Whenever packet transmission completed, the cluster head node verifies the packet and if it is validity, ACK packet is send back, and the other node increases its trust value in its time slot, otherwise, NAK packet is send back, and the trust value of the other node decreases. Over a period of time of data transmission, the cluster head nodes will send the results to the base station after data fusion.

3.4 Algorithm Design

Step 1. Initialize trust value of the node and a timer. Generate a random number, each node compute it's $P(i)$ according to the formula (8). Choose the cluster head nodes.

Step 2. Compute the delay of cluster head nodes to the base station according to formula (7), deliver the clustering packet RREQ and delay information.

Step 3. Compute the delay information from the other node to the neighbor cluster head nodes. Under the condition of meeting user's delay requirement, compute the trust value of the neighbor cluster head nodes.

Step 4. Send the request join packet RREQ from the general node to the cluster head node which has the maximum trust value.

Step 5. Under the control of the cluster head nodes, the regular node transmits its packet in its time slot. Update its trust value according to formula (4), the cluster head nodes exchange information with base station and update its trust value.

Step 6. If time out, go to Step 2, otherwise, go to Step 5.

Performance Evaluations

Simulations have been done on NS (Network Simulator) 2 platform. It was assumed that 200 sensor nodes were distributed randomly over a square area of 10 m× 10 m. Our proposed algorithm (Called HEED-T) was compared to AntQA[6] and LEACH. Same as [6], the initial energy of the sensor nodes was 0.5 J. Comparing the above algorithms through three aspects: node survival ratio (NSR); packet delivery ratio (PDR) (malicious nodes may refusal to retransmit packets) and packet

validity ratio (PVR) (malicious nodes may modify the real data). Simulations are shown in Fig. 1, Fig. 2 and Tab. 1. It can be found that the proposed algorithm has better performance.

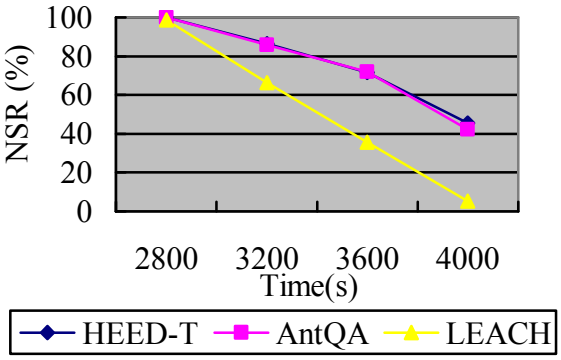

Fig.1 Comparison of Node Survival Ratio

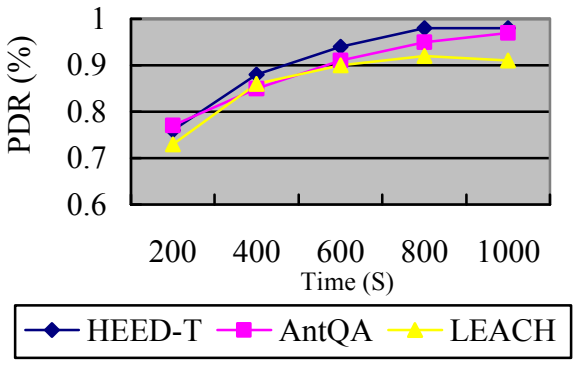

Fig. 2 Comparison of Packet Delivery Ratio

Tab.1 Comparison of PVR

Time(s) / Algorithm	2800	3200	3600	4000
HEED-T	100%	100%	100%	100%
AntQA	100%	97.6	91.2	87.8
LEACH	95.7	93.2	86.5	81.0

Conclusion

In this paper, a trust-based QoS routing algorithm is proposed. Three factors: Energy efficient, packer validity and QoS constraints are considered to modify the HEED protocol. Simulations have shown that the proposed algorithm is both feasible and effective.

Keywords: Self-certified Public Key Cryptology; Discrete Logarithm Problem; Ring Singcryption; Bilinear Parings

Abstract. This paper analyzes and summarizes existing ring signcryption schemes, combined with self-certified cryptosystem and ring signcrypption, we proposed a self-certified ring signcryption based on Discrete Logarithm Problem. The scheme proposed not only guaranties ring signcrption's anonymity, confidentiality, unforgeability and other security features, but also solves certificate management and key escrow issues, which can save storage space and communication cost. By removing bilinear pairings in the process of design, the efficiency of this scheme has been greatly improved. Concluded from the experimental results, this scheme has the advantages of high computational efficiency, high security, and low communication cost.

Introduction

In 2001, the concept of ring signature was first proposed by Rivest et al[1]. Ring signature is similar to group signature, which was proposed to leak information anonymously. Any user in the ring can use their private key and public key of other members to sign messages without all members' consent. The message receiver can only determine the signature from which groups but don't know the actual signer, only the actual signer can reveal its true signer identity, so the signer's anonymity is fully realized. Since then, some effective ring signature schemes were proposed by scholars.

Two of the most basic and most important services of Public key cryptography are secrecy and authentication, and usually both properties are required in many cryptographic applications. The traditional approach is signature then encryption, while in 1997, Zheng[2] introduced the concept of signcryption for the first time, which enabled us to achieve both encryption and signature in a single logical step, it was more efficient compared with the traditional signature-then-encryption approaches. Since then many effective signcryption schemes have been proposed.

The concept of Self-certified public key was first proposed by Girault[3] in 1991. It has two advantages as follow: (1)Save storage space and communication cost by not using certificates. (2)Reduce the quantity of calculation by not applying additional verification using public key. On this basis, scholars have proposed some self-certified signcryption schemes.

Ring signcryption was proposed in 2003, it not only has the functional features of ring signature, but also it is equally efficient as signcryption. Under such circumstances, scholars proposed many ring signcryption schemes[4], for example Yu[5] proposed the first self-certified ring signcryption scheme which combined the concept of ring signcryption and self-certified cryptosystem, but it is based on bilinear pairings, so the computational efficiency of scheme is decreased.

To improve the efficiency of ring signcryption, so we proposed a self-certified ring signcryption without paring which is based on the intractability of the discrete logarithm problem in the finite field.

Preliminaries

Related complexity assumptions

p, q are two prime numbers and satisfied the conditions of p | q-1. Let G be a cyclic additive group of prime order q, and g $\in F_P^*$ be a generator of G. At first, this paper assumes that for any polynomial time algorithm, the following problems do not have advantages that cannot be ignored to solve it.

(1) The discrete logarithm problem (DLP): Given element g, $g^a \in F_P^*$, and we need to compute a $\in F_P^*$.

(2) The computational Diffie-Hellman problem (CDHP): a, b $\in F_P^*$. Given g, g^a, $g^b \in F_P^*$, and we need to compute $g^{ab} \in F_P^*$.

Self-certified signcryption scheme based on discrete logarithm problem

Description of Scheme

(1) Setup: ① PKG chooses p_1 and q_1 as two large prime numbers, and they are both satisfied $p_1 = 2p' + 1$, $q_1 = 2q' + 1$. p' and q' are large prime numbers too. PKG computes $p = p_1 q_1$, choose g as a generator which prime order is $p'q'$. Then, KGC chooses some cryptographic hash functions as follows: $H_0 : \{0,1\}^* \times F_P^* \to F_P^*$, $H_1 : F_P^* \to \{0,1\}^n$, $H_2 : \{0,1\}^* \to \{0,1\}^L$, $H_3 : \{0,1\}^* \to Z_q^*$, $H_4 : Z_q^* \to \{0,1\}^n$, $H_5 : F_P^* \to F_P^*$.

② Then PKG randomly selects a secret value $x \in F_P^*$ as a master key of system, and compute its public key $y = g^x \bmod p$.

③ PKG keep (p_1, q_1, p', q', x) as secret. And publishes the system parameters （p, g, y, H_0, H_1, H_2, H_3, H_4, H_5） for the use of all users.

(2) Key Generation: The identity of the user U_i is d_i. User U_i romdomly selects a secret value $r_i \in F_P^*$, and computes $y_i = g^{ri}$. Then Ui send （d_i, y_i） to the PKG through a safe channel. After received（d_i, y_i）, PKG computes $Q_i = H(d_i, y_i)$ and $X_i = g^x Q_i$, and transmits it to the user Ui through security channel. After received （Qi, yi）, The user U_i can verify the legitimacy of the X_i by computing $y^{Qi} = X_i \bmod p$. If equation is holds, the user U_i computes $Si = r_i H_5(X_i)$ as his private key, and yi as his public key.

User's identity, public key and private key are （d_i, y_i, S_i）.

(3) Ring signcryption: There are user group U= {U_1, U_2, …. U_n}. Let user U_s who stands for the group U signcrypt message m. the user U_s as a member in the ring to signcrypt message m. The user U_s's identity is d_s, public key is y_R , and the private key is S_R. User U_s sends ciphertext to receiver whose identity is U_R. Then, the user U_s performs as follows.

1). User U_S randomly chooses k$\in F_P^*$, and compute $R = g^k \bmod p$.

2). User U_S selects r$\in \{0, 1\}^L$, keep r secret, then compute t=H(y_1... y_{s-1}, y_{s+1}... y_n, r).

3). For any i≠s, choose $U_i \in F_P^*$, then compute $h_i = H(d_R, y_R, U, U_i, t, m)$.

4). If i=s, compute $U_s = r_s Q_s - \sum_{i=1, i \neq s}^{n} (u_i + h_i Q_i)$, $h_S = H(m, U_S, U, y_R, d_R)$.

5). Compute $V = y_R^{h(y^{QR})(r_s + X_s)}, c = H_4(V) \oplus m$.

6). Compute $S = H_1(m, R) g^{-k} g^{S_s(r_R + X_R)}$.

Then send the ciphertext Ω={t, S, U, c, U_1, U_2,….U_n} to user U_R.

(4) Unsigncrypt: When the user whose identity is d_R receives ciphertext Ω={t, S, U, c, U_1, U_2,….U_n}, the receiver decrypts the ciphertext as follows.

1). For all i$\in$(1, n), check whether $hi = H(d_R, y_R, U, U_i, t, m)$, if all the equations hold, go to the next step. Otherwise reject the ciphertext Ω.

2). Compute $V' = y_s^{h(y^{Q_S})(r_R + X_R)}$, and recover the message by computing $m' = H(V') \oplus c$, If m= m′, means that the received message is correct.

3). Compute $V = R^{S_R(r_s+X_s)}$

4). Check that the equation $RS = H(m,R)\, y_s^{h(y^{Q_s})(X_R+r_R)} \bmod p$.

Correctness Analysis.

$$V = y_R^{kh(y^{QR})(r_s+X_s)} \bmod p = g^{r_R kh(y^{QR})(R_s+X_s)} \bmod p$$

$$= R^{r_R h(X_R)(r_s+X_s)} \bmod p = R^{S_R(r_s+X_s)} \bmod p$$

$$RS = g^k H(m,R) g^{-k} g^{S_s(r_R+X_R)} \bmod p = H(m,R) g^{r_s H_3(X_R)(r_R+X_R)} \bmod p$$

$$= H(m,R) y_s^{H_3(y^{Q_s})(r_R+X_R)} \bmod p$$

Security Analysis

Unforgeability.

PKG is credible: when an external attacker wants to signcrypt by faking a user in U, in order to construct a signature S which receiver can accept it. He must know the private key S_S of sender U_S .When attackers don't know private key of any member of user group, he want to solve S_S must faces discrete logarithm problem. and we all know it is difficult.

PKG is not credible: If PKG reveals part of private key X_s of signer U_s to attacker, but due to $S_s = r_s H_5(X_s)$, r_s in the equation is the secret value selected randomly by user, so it has a certain randomness, getting r_s also belongs to the difficulties of CDH problem through $y_s = g^{r_s}$, So it is hard to get the private key of signer, the attacker can't forge the signature.

Anonymity.

The design for this scheme is symmetrical, so as to attacker, any user in the users group U has the same power to signcrypt message, their probabilities are equal and they are 1/n. The probability that an attacker guesses signer correctly is not exceed 1/n .So the scheme satisfies anonymity.

Confidentiality.

Assuming attackers obtained ciphertext, If he wants to extract the message m from the ciphertext Ω={t, S, U, c, U_1, U_2,….U_n }. Attacker must know the value of V, but $V' = y_s^{h(y^{Q_s})(r_R+X_R)}$, and it is not feasible to get the value of V by this equation. because this procedure belongs to the difficulties of DLP. Therefore, in addition to any attacker outside user U_R can not recover the message m from the ciphertext Ω. So the scheme satisfies the confidentiality.

Authentications.

Through the scheme shows that any other users except U_s in user group can not prove that he is a real signer, because verify information(y_1... y_{s-1}, y_{s+1}... y_n, r)through equation t=H(y_1... y_{s-1}, y_{s+1}... y_n, r),it belongs to the problem of original image of hash function, and it is very difficult on the calculation. So in this scheme, only signer himself can prove his real signer identity.

Efficientibility.

With this scheme with [4] [5] comparing their efficiency, and H stands for Hash operation, P stands for bilinear operation, E stands for exp operation, G_{1M} stands for scalar multiplication of G_1, G_{2M} stands for multiplication of G_2, G_{1A} stands for addition of G_1. Comparative analysis of results are shown in Table 1 as follows:

Table 1.The results compared with [4-5]

scheme	Ring signcryption	unsigncryption
scheme[4]	2nP+(n+3)H+2G_{1M}+nG_{1A}+nG_{2M}	(n+2)P+3H+nG_{2M}+n G_{1M}
scheme[5]	(n+3)G_{1M}+(n+1)H+P+E+nG_{1A}	(n+1)H+3P+(n+1) G_{1A} +n G_{1M}
Our scheme	5E+4H+3 G_{1M}+(n+2) G_{1A}	(n+3)H+5E+3 G_{1A}+5 G_{1M}

Analysis in Table 1, we can see , our scheme does not use bilinear pairings. And compare with other operations such as pow operation , scalar multiplication and other operation, bilinear pairings is still are time-consuming and complex operation. In the whole ring signcryption and unsigncryption procedure, both scheme[4] and [5] used bilinear operation. And we all know the

bilinear pairing computation efficiency is relatively low, so our scheme is more efficient in calculation compared with scheme[4][5].

Conclusions

On the basis of intractability of discrete logarithm in the finite field, and combined with self-certified cryptosystem and ring signcryption, this paper proposed a self-certified ring signcryption. The scheme has the following characteristics: KGC only has part of users' private key, so it can't impersonate the user and forge signature; this scheme realizes the confidentiality and authenticity of the message within a logical step, and realizes full anonymity of the signcrypter. If necessary the signcrypter can publicly verify its true identity; The efficiency of the scheme has been improved by not using bilinear pairings. Through comparative analysis, this scheme we proposed has greatly improved the efficiency of signcrption.

Keywords: Ontology, Electronic Government, Workflow, Meta-Model

Abstract. The paper, in which Government Affair Workflow Model as an illustrated application is discussed, clarifies nature and concept of Ontology. Based on the characteristics of the workflow model and application of Government Affair Workflow , this paper puts forward Government Affair Workflow Model and creates a Workflow Meta-Model, Document Meta-Model and Determent Meta-Model and offers framework of OWL+RDF+XML. It is proved in the experiments that Ontology can be applied effectively in Government Affairs Workflow.

Introduction

With the rapid development of the technology of computer hardware and software and Internet, OA has been widely studied and applied. To fit political system reform and government innovation, electronic government has also become a research focus. For the government, different from the common OA system, electronic government not only needs to attain simplifying structures and increasing work efficiency of the government after finishing routine work, but also tries to serve the people to the utmost extent and establish a good image in their hearts for the government. So the construction of electronic government includes the construction of internal and external information of the government and better integration of these systems.

In addition, due to relatively clear intelligence division in the current government, it needs the cooperation among several government departments to finish a task. To improve work efficiency of the government, not only the cooperation among the departments should be enhanced but the parallelism of work should be increased. As core technology of a process modeling and a process management, management technology of workflow can be effectively combined with other applied systems, and produce various vocational management systems which meet the demand of the government such as OA, project management software and PDM system etc. Therefore, electronic government system suits for adopting workflow technology to build system model. A large number of different government processes exist in government departments, and there are different ways adopted to depict government processes. At present, the most promising technology about the communication of common concept is Ontology which is based on RDF semantic network of W3C company.[1] Therefore, as Government Affairs Workflow Meta-Model, Ontology technology can be used as the main described technology.

The Whole Hierarchical Structure

Workflow is a computerized model reflecting vocational process. It is also a vocational model operated by Workflow management system to achieve business process integration and process automation in the advanced computer environment. Workflow technology is a core technology which realizes business process modeling, business process simulation analysis, business process optimization, business process management and integration and ultimately accomplishes business process automation. In government affairs process, putting Workflow into business process modeling and deep analysis can standardize the government business process, discover the unreasonable parts in business process and optimize and restructure government business process. Moreover, business process model itself is the important knowledge base and rule base, so it can be a model directing to operate computer management information system.[2]

Philosophically, Ontology studies nature of objective things; in the engineering sense, Ontology refers to a concept or a terms in a field. According to W. N. Borst, Ontology is defined as a formal, explicit specification of a shared conceptualization. [3]The purpose of constructing Ontology is to achieve Knowledge sharing and reuse to some extent. Combining with multilayer technology framework and Workflow model developed and supported by W3C, the paper puts forward layer framework structure of Ontology model (see Fig. 1).

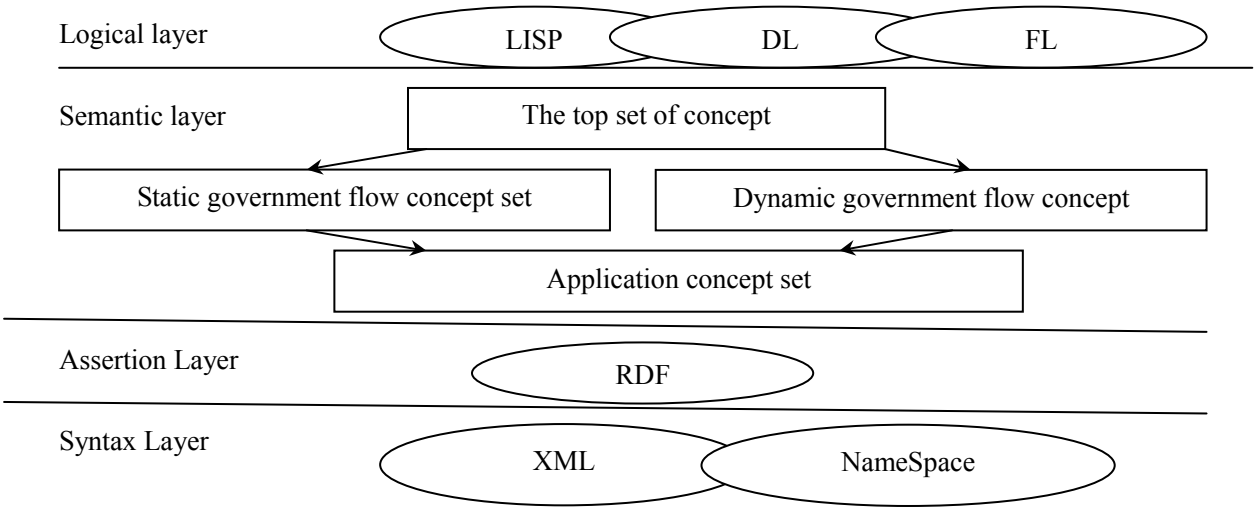

Fig. 1.The Model Framework of Government Affair Workflow Ontology

(1) Logical Layer: It is the foundation of achieving the reasoning function of Government Affair Workflow Ontology Model. It inquires of the concepts of semantic layer, property and example by Artificial Intelligence such as DL, FL, and Lisp etc. and logically reasons them, ultimately forming Government Affair Workflow expert system with reasoning function.

(2)Semantic Layer: It is the core of Government Affair Workflow Ontology Model and includes The top set of concepts, Static workflow concept set, Dynamic workflow concept set and Application concept set, among which Static workflow concept set and Dynamic workflow concept set belong to intermediate concept set. These concepts have nothing to do with government departments, but are the concept sets which Government Affair Workflow model mainly studies. The top set of concepts chiefly involves the most basic concepts, properties and semantic relations connected with government activities such as time, space, object, event and behavior etc; Static workflow concept set mainly refers to the most basic concepts about time, space and object in government field such as civil servants, government institutions, working documents and various archives; Dynamic workflow concept set mainly shows the most basic concepts about event and behavior in government field such as official document circulation, civil servant switch and document classification; Application concept set indicates the concepts connecting with government department resources and government transfer activities.

(3)Assertion Layer: It establishes the connection between metadata and described resources in a standard way, thus ensuring that computer is able to clearly identify the meaning of metadata and its relation with the resources. Currently, RDF is becoming a basic assertion mechanism in a network environment.

(4)Syntax Layer: It is a markup language standard, which marks the above three layers in a way computer can understand and handle. At present, as the markup language of network resources, XML is becoming the basic markup language of semantics and knowledge. Furthermore, it also needs data encoding and the standard which the resources show such as Unicode and URL.

Government Meta-Model and Ontology Description

Basic Meta-Model made by WFMC is a model used to depict the internal connection of workflow model. It describes different objects, the relations among different objects and their properties. In addition, using this Meta-Model helps to establish model which is able to exchange information among many workflow products.[4]

In terms of modeling approach of workflow model and combining with the process of government work, the paper presents the abstract Government Affair Workflow model in Fig.2. Two main parts are included here: The first part finishes the design of government process, and the second part finishes the execution of government process. The paper researches the main applied method of Ontology in the design stage of government process. The paper won't focus on the fact that the popular frameworks such as J2EE, Struts and NET are adopted to accomplish the run phase of government process.

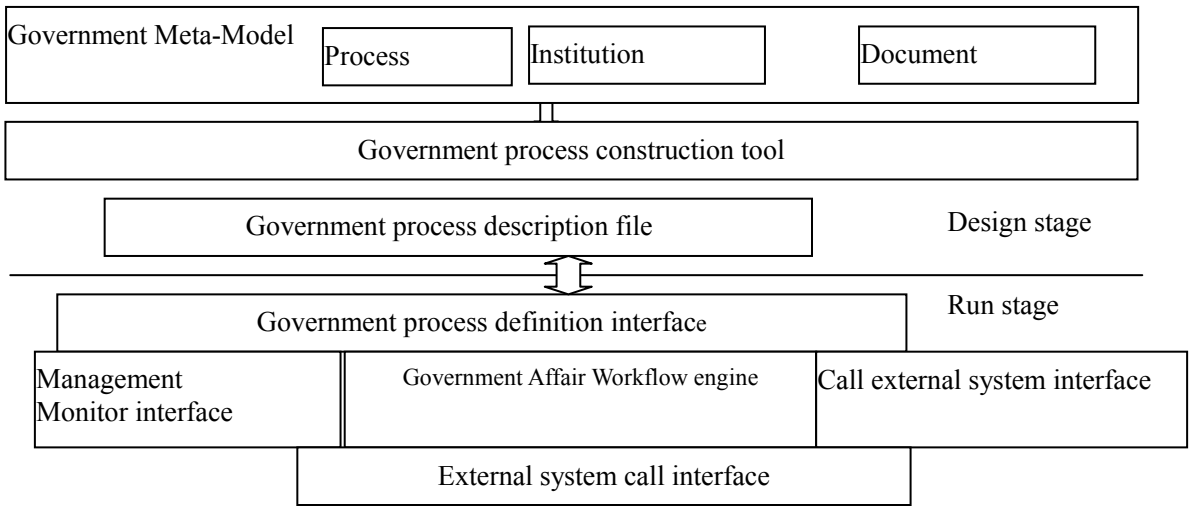

Fig. 2 The abstract Government Affair Workflow model

3.1 Government Meta-Model

Government Meta-Model is composed of three parts: process Meta-Model, institution Meta-Model, document Meta- Model.

Government process Meta-Model uses process object, activity object, route object and control object etc. to depict a government process. As for the characteristics of government process, we need extend and simplify the basic Meta-Model in some fields. We lead a series of relevant concepts into the study and remove some objects and properties used less in government process definition.

Since government authorities have clear division, special staff administrates special tasks, which contributes to government administration, but also increase the flexibility of work. The reengineering of government process is put forward on such a kind of premise. Moreover, how to reengineer government process and what kind of model will be r reengineered have been the issues which need to be discussed deeply. Based on Government Affair Workflow model mentioned here, the paper also presents government institution Meta-Model and government document Meta-M model. Government institution Meta-Model is used to describe the relations of various staff, departments, and posts in the government. Government document Meta-Model is used to depict the composition of using documents, the types of different elements constituting documents and permissions in government process.

Government process Meta-Model is the core in these three parts and builds the link with government institution Meta-Model and government document Meta-Model. To enhance the flexibility of government process description, we have some expansion in government Meta-Model: (1) in government circulation Meta-Model, activity object and control object are separated and the information, concerning with process control information such as convergence and divergence structures, is described by control object in order to increase the flexibility and modifiability of process description. (2) Different objects in government Meta-Model needn't give a complete definition at the moment of process definition. According to the practical process running state, evaluation can be provided during the course of process running, which can increase the flexibility of government process. Through government Meta-Model, we needn't define completely the activity at the definition stage, but can finish handling it at the running period in terms of the property of activity object when touching different sub-processes of government. (3) In government Meta-Model, the relevance between activity object and document object leads to the connection

between government process Meta-Model and government document Meta-Model. In the process of government circulation, the information on the direction of circulation and the participants of activities can be dynamically determined in terms of the contents of government documents. (4) In government Meta-Model, the relevance between activity object and character results in the relations between government process Meta-Model and government institution Meta-Model. Government Meta-Model can adopt dynamic character to describe activity participants. Dynamic character possesses a certain generating rule, so according to the information about government institution and the choice of participants at the stage of process execution, participants will be automatically generated in the next activity, and that way process user can dynamically change process participants according to the actual situation. At the same time, it can ensure that the optimization of government institution can't influence process structure.

3.2 Ontology Description of Government Meta-Model

To adopt to he complexity and polytrope of government work, a government process construction tool is added in government Meta-Model and government process description document. The tool will provide a graphical interface to directly finish the direct allocation of government process description document and then the allocated document will achieve the alteration and reconstruction of relevant tasks in government Meta-Model to increase flexibility of handling tasks. In the paper, government process description document chiefly uses Ontology language to construct, and it possesses the main functions as follow:

(1)At the initial design stage of government process, Ontology can conserve the design result of government process and put it into the file so that it can present shared knowledge data and indication to get better allocation and government process installment in addition to a certain intelligence decision instructions. In the phase of government process execution, corresponding data can be checked and conserved. As the input of Government Affair Workflow engineer, Ontology language can provide workflow engineer with control information and correctly control government process and make it follow the plan to execute normally. (3) During the course of government circulation, Ontology language establishes own Government Process Description Document for every circulation process. In addition, workflow can finish the dynamic revision and allocation of description documents. The accomplishment of the revision and allocation of government process doesn't influence the circulation and allocation of the other business process.

Conclusion and Outlook

With the idea of workflow, the main tasks in government departments are applied to the consolidated shared platform Ontology provided, thus making government leaders and the common civil servants work better and effectively avoiding the appearance of the isolated information island.

In our opinion, Ontology is an effective knowledge indication and shared way, and is able to organize knowledge in a field better; Workflow management technology is a core technology of process modeling and process management, and conveniently integrates task process of government. Government Affair Workflow model which Ontology is used to show possesses a certain reference significance for achieving government management system and electronic government system.

Based on the above research results, we are developing and designing protosystem and deeply discussing electronic government model based CSCW.

Keywords: Boolean Network; Dynamical Analysis; Information Entropy

Abstract. Random Boolean networks have been proposed as a basic model of genetic regulatory networks for more than four decades. Attractors have been considered as the best way to represent the long-term behaviors of random Boolean networks. Most studies on attractors are made with random topologies. However, the real regulatory networks have been found to be modular or more complex topologies. In this work, we extend classical robustness and entropy analysis of random Boolean networks to random modular Boolean networks. We firstly focus on the robustness of the attractor to perturbations with different parameters. Then, we investigate and calculate how the amount of information propagated between the nodes when on an attractor, as quantified by the average pairwise mutual information. The results can be used to study the capability of genetic information propagation of different types of genetic regulatory networks.

Introduction

Networks' normal performance are essential to the stabilization of nature and human society such as random Boolean networks (BNs) [1]. BNs have been used to study global dynamic properties of biological networks, particularly as models of gene regulatory networks. In this context, the Boolean variables are used to represent the genes [2].

There're many kinds of BNs, one of them is random Boolean networks (RBNs) [3]. RBNs behave a rich variety of dynamical preferences, which don't assume any particular functionality or connectivity of the random generated nodes and are generic. The properties and abundance of attractors have been focused by much work. The RBNs' topologies with one input per node can be looked as graphs of random maps. Due to the corresponding topology, there's an access to investigating random maps and finding analytical results for attractors in RBNs. At the same time, there's some strong differences that emphasize the difficulties in making direct comparisons between RBNs and real systems [4].

The asymptotic dynamics of RBNs subjected to random fluctuations is investigated. Under the effects of noise, the system can escape from the attractors of the deterministic model, and a thorough study of these transitions is showed. The sets of attractors can more properly describe dynamics rather than single ones. Through interpreting RBNs as models of genetic regulatory networks, it suggests the threshold ergodic sets [3].

According to a Boolean function and the current state of its input nodes, all nodes are synchronously updated at every time in synchronous networks. RBNs present a rich boundary of dynamics. In particular, groups of BNs fall into two broad dynamical regimes: order and chaos [5]. The dynamic regime of the network can be determined from its response to perturbations, such as a deviation from the behavior prescribed by the topology and logic of the network. In general, ordered RBNs are very robust to perturbations – they behave similarly to the unperturbed network – however they lack the ability to respond differently to different perturbations. RBNs in the chaotic regime tend to magnify small perturbations until the entire behavior of the network changes. Because of that, their responses to similar perturbations differ widely.

The most usual method to measure the response to perturbations is to assess the number of nodes which are in different states. These assessments of robustness studied the response of RBNs to perturbations, starting from random states [6]. Information propagation in RBNs also has been assessed by other methods, which also found maximization at the critical regime [7].

So far, there are some researches on the RBNs and they have gotten some results [8]. In a large, complex network of interacting elements, such as a genetic regulatory network, the average of the mutual information over all pairs is a global measure of how well the system can coordinate its internal dynamics. They study this average pairwise mutual information in random Boolean networks RBNs as a function of the distribution of Boolean rules implemented at each element, assuming that the links in the network are randomly placed [9].

Based on the fact that real RBNs are modular [10] and most studies have been made over random topologies, it is important to study the properties of robustness and information propagation in RBNs with modular topologies. Therefore, in this paper, we extend classical robustness and entropy analysis of random Boolean networks to random modular Boolean networks. In one hand, we focus on the robustness of the attractor to perturbations with different parameters. In another, we investigate and calculate how the amount of information propagated between the nodes when on an attractor, as quantified by the average pairwise mutual information.

Definition of the robustness and mutual information entropy

In a biological setting or genetic regulatory system, we expect that both the ability of the network to process information and its robustness. Particularly for RBNs, it is important to calculate these two different indices. Based on the work in [9], we extend their methods to the random Boolean networks with modular topologies.

Firstly, we define the robustness index of an attractor, *RA*, which can be quantified by the fraction of the number of single-node perturbations from all states of all the possible attractors after which the network returns back to the original attractors. Here, we use single-node perturbations, which could be formally defined as the probability that a trajectory starting from a state on an attractor with one node perturbed, will return to that attractor.

Then, we define another index, mutual information entropy, *IA*. The different levels of mutual information entropy are defined as follows.

Let S_a be a process that generates a 0 with probability p_0 and a 1 with probability p_1. We define the information entropy of S_a as

$$H[S_a] = -p_0 \log_2 p_0 - p_1 \log_2 p_1 \tag{1}$$

Similarly, for a process sab that generates pairs *ab* with probabilities p_{ab}, we define the joint information entropy as

$$H[S_{ab}] = -p_{00} \log_2 p_{00} - p_{01} \log_2 p_{01} - p_{10} \log_2 p_{10} - p_{11} \log_2 p_{11} \tag{2}$$

For an instance of RBNs, we may consider running the dynamics for finitely long times and starting from all possible initial configurations which can be evolved to some attractor. The value of p_{ab} for the process is given by the fraction of time steps for which node *i* has the value a and on the next time step node j has the value *b*. Then, the mutual information entropy of the pairwise *ij* could be defined as

$$M_{ij} = H[S_i] + H[S_j] - H[S_{ij}] \tag{3}$$

Therefore, the mutual information entropy between the time series of two nodes of a Boolean network with modular topologies, with the output time series shifted by one time step *IA*, can be used as a measure of the amount of dynamical correlation between an input and an output. We use the average mutual information between all nodes as a measure of the average efficiency of information propagation in the network as following equation

$$\langle IA \rangle = \left\langle N^2 \sum_{i,j} M_{ij} \right\rangle \tag{4}$$

It has previously been observed that $\langle IA \rangle$ is maximized near the critical regime in numerical simulations of random Boolean networks with a small number of nodes.

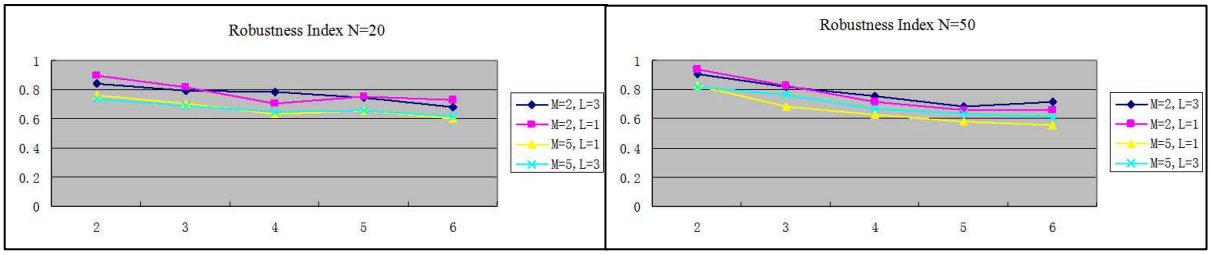
Algorithms and numerical simulation results

As the state of the Boolean network may have kinds, therefore, we need to use backtracking search. It is about the current state and status before looking for ways to compare iterative sequence repeat state to find the attractor. Depending on the nature of synchronous RBNs, if there are duplicate states in the iterative sequence, all the subsequent states are repeated. Therefore, in order to reduce the computational complexity, every T iteration step can conduct a retrospective search.

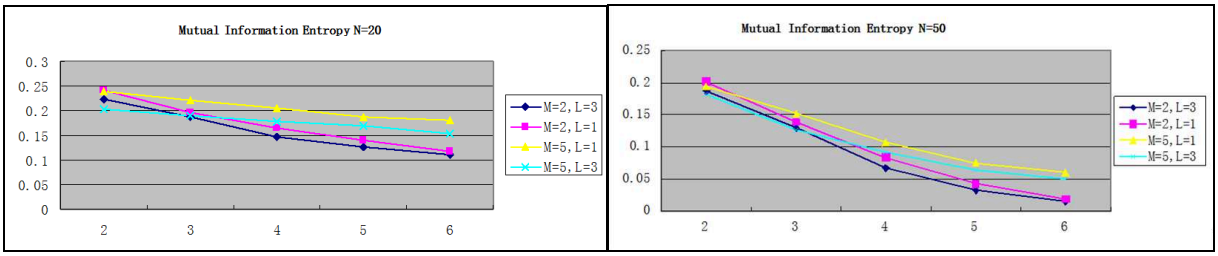
When calculating the robustness, we use this method to search the attractor: T is taken as 1/10 of iterations of having been conducted attractors, and keeps on updating constantly. After searching the attractor, we keep the current state as a starting point for half of the nodes are applied perturbation, and iteration. If the iteration to the previous state of a disturbed state with the same step, then stop the iteration, remember back to the times of the original disturbance attractor. If the iteration has reached the attractor, but still did not appear the state of disturbance before, then stop the iteration, the second disturbance failed to remember back to the original attractor. Counting the proportion of the times that disturbed status come back to the original attractor add up to account for the disturbance times， then we get the robustness index

When calculating the mutual information entropy, in order to search for duplicate state for the first time the iterative sequence, we shall fetch as 1 T, or search by tracing each iteration step. At the same time, record the number of nodes to take the number of "0" and "1" and take "00", "01", "10" and "11" .After the search to the attractor, according to the records of each node and node, the number of the various values obtained by the probability of their various values, then the probability of their various values are put into mutual information entropy formula, we can get the mutual information entropy.

The calculation results are in the following graphs.



As we can see, robustness index decreases with the increasing of K value. When the module is strong, that is, the value of M is larger, there has less robustness index. With respect to K, M, L has the less effect in the robustness index, but we can see that when the module is strong, the test group which L is larger has the higher robustness index than the smaller one.



We can see from the figure that the mutual information entropy increases with the K value decreases. When L is small, mutual information entropy is larger. The modularity of mutual information entropy affect y related to the K value. When K = 2, the interactive of low entropy test module set is large, and when K> 2, the interactive of the high entropy test module set is large. In other words, high modularity reduces the speed of the mutual information entropy decreases with the increase of K. Besides these, we also found that when the larger network size, the N value larger, and the value of mutual information entropy decreased greatly.

Conclusion

Since the modularity plays an important role in evolution of biological systems, it is necessary to extend classical robustness and entropy analysis of random Boolean networks to random modular Boolean networks. Based on the analysis and calculation of the robustness and pairwise mutual information entropy in this work, we find that the dynamical behavior and properties of attractors in random Boolean networks are quite different from those in random modular Boolean networks. This investigation of the robustness of the attractor to perturbations and the capability of genetic information propagation with different parameters could be the new viewpoint to explore the mechanism of realistic genetic regulatory systems.

Keywords: Network Instruction; Interaction; Interaction Mode; Network Instruction Platform

Abstract. The quality and effect of network instruction is largely affected by the effectiveness of network instruction interaction. Firstly, we explain the definition and elements of network instruction interaction, as well as the concept of interaction of network instruction platform. Then, we focus on the overall analysis of network instruction interaction from the horizontal and longitudinal aspects. In the horizontal analysis, we discuss the network instruction interaction mode in detail. In the longitudinal analysis, we integrate all the instruction modes to introduce the instruction interaction hierarchical model. As the network instruction platform is a key element in the implementation of network instruction, its interactivity greatly affecting the effectiveness of network instruction as well, we finally design network instruction interaction mode including interactive classification and overall architecture of network instruction platform, in order to provide information technology support to create flexible network instruction interaction environment.

Introduction

Interaction is one of the basic characteristics of instructional activities. In the various forms of instructional activities, interaction approaches are different. With the rapid development of information technology, advances in network technology, communication technology and multimedia technology have not only promoted the changes of instruction form, but also have promoted the development of instruction interaction theory. Interaction has become the term widely used in the field of network instruction. Research scholars [1-3] argue that many new technologies own interactivity and make it easier to create instruction environment. In such kind of environment, students can learn through practice, get feedback, continue to improve their understanding and build new knowledge. Network instruction based on Internet and multimedia must and only has rich interaction mechanisms in order to truly achieve the goal of network instruction, to inspire the power and desire of students to explore knowledge, and to intuitively provide learning contents.

Network instruction platform with rich interactivity is the demand of network instruction, and is the necessary requirement to play the effectiveness of network instruction. How to fully understand and design interaction mechanisms of network instruction platform has become an important part of design, development and evaluation of this platform. Currently, researches on interaction of network instruction platform mostly focus on the analysis from the technical point of view on how to design and develop interactive means, and have less analysis from the instruction application level point of view on meanings and characteristics of interactivity. In this paper, based on the related concepts we focus on network instruction interaction from two aspects of horizontal and longitudinal analysis, and design network instruction interaction mode.

Related Concepts

The meaning of network instruction interaction. In the researches on the instruction interaction under the network environment, the explanations and descriptions of its meaning mainly include as follows.

- Merrill, LI and Jones believe that learning interaction is a real-time, dynamic and mutual giving extraction process including the exchange of relevant information between instruction system and students [4].

- Gilbert and Moore believe that instructional interactivity based on computer-media refers to information exchange between students and technology [5].
- Professor Wagner believes that interaction is the mutual influence and information exchange between individuals and groups, requiring interaction between two subjects and two kinds of activities [6].
- Chen Li believes that instruction interaction is an event occurring between students and learning environment, which includes students and teachers, as well as exchanges between student and student, and includes mutual exchange and interaction between student and a variety of physical resources [7].

Taking these above descriptions, we can conclude the definition of network instruction interaction. Network instruction interaction refers to under the network environment for the realization of the instructional target interactive events between students, network instruction resources and teachers. The events include social interaction between student and teacher as the subject, the interaction and communication between subject and network instructional resources as the object, as well as the dynamic change process of network instructional resources.

Element analysis of network instruction interaction. Any instruction system includes three elements, i.e. teachers, students and curriculum resources. Curriculum resources include instructional media and instructional information. Network instruction system as a special instructional system contains three factors, i.e. teachers, students and network instruction platform. In fact, network instruction interaction shown in Fig.1 refers to the interaction and relationship between teacher, student and the network instruction platform.

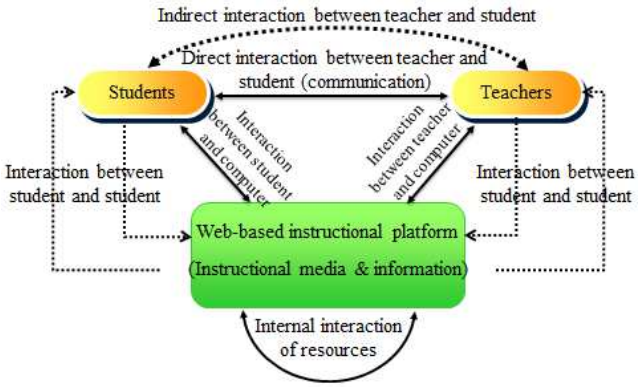

Fig.1. The interaction between the various elements of network instruction

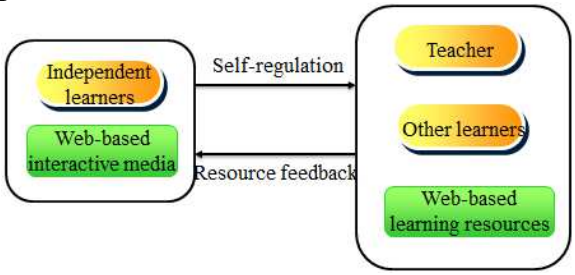

Fig.2. Individual independent interaction mode

The interaction definition of network instruction platform. The interaction of network instruction platform one hand refers to dynamic representation and generation of instruction information, on the other hand refers to information and emotion exchange activities formed by interaction between students and teachers in the network instructional process.

The interaction purpose of the network instruction platform is to enable students to change their behaviors through mutual communication and interaction in the network learning process in order to achieve network instruction goals. When this interaction enables students to respond to students' behavior toward the direction of instructional objectives, the network instruction is effective. Therefore, the interaction of network instruction platform is focused on how interactive activities make an effect on the meaning of student learning.

Horizontal Analysis of Network Instruction Interaction Based on Network Instruction Interaction Mode

Individual independent interaction mode. In the individual independent interaction mode shown in Fig.2, instruction interaction includes three main elements, i.e. independent learners, web-based interactive media and web-based learning resources. Independent learners through web-based interactive media conduct self-regulation to web-based learning resources. Then, according to learners' self-regulation these resources generate learners' requirements of learning resources as called resource feedback.

Cooperative interaction mode. The elements of cooperative interaction are learners, web-based interactive media, teacher and web-based learning resources. Learners are members of a learning community, and are the main aspects of interaction. There exists collaboration and equal communication between learners, as well as a competitive and opposite relationship. Teachers are responsible for the monitoring and guidance of the entire group interaction process, and undertake to establish learning goals, to assign learning tasks and to divide into groups. Web-based interactive media and web-based learning resources constitute learning environment for entire team to cooperate and interact. Learner can communicate with other cooperative members through interactive media and can obtain learning tips or advices from the teacher. Web-based learning resources can provide a wealth of learning information for learners in a team. Therefore, the learner according to his own learning task assigned in a team selects his desired contents from these resources and cooperates with other group members to complete the learning tasks. The specific interaction mode is shown in Fig.3.

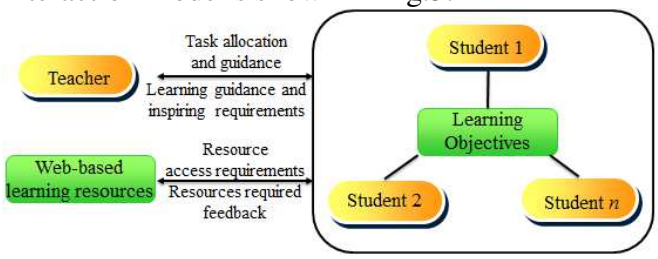

Fig.3. Cooperative interaction mode

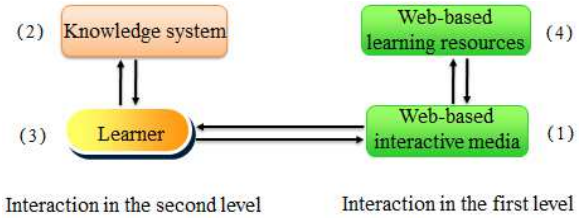

Fig.4. Individual interaction mode

Interactive-object-based interaction mode. The interaction mode based on interactive object mainly includes three aspects as following.

1) *Individual interaction mode*. The elements of individual interaction mode include learner and web-based learning resources. Teacher and web-based interactive media are only in a supplementary role, not as the main factors to be considered.

The learner gets new knowledge and information data from web-based learning resources through interactive media. Then, the learner will compare his acquired information with his existing knowledge system, in order to make his original knowledge assimilate new information through applying interaction mode between learner and teacher. When new information cannot be assimilated by learner's knowledge system, the learner should be required to get more information from learning resources to support assimilation or reconstruction of knowledge architecture. Finally, the learner continues to draw more relevant knowledge and information from web-based learning resources through interactive media. The specific interaction mode is shown in Fig.4.

In these four steps, (1) and (4) is an external exchange process between learner and web-based learning resources, whereas (2) and (3) is an internal communication process of learner himself. It is obvious that the basis of (2) and (3) is (1) and (4), thus we define (1) and (4) as interaction in the first level, and (2) and (3) as interaction in the second level.

2) The interaction mode between students and teacher. Learners and teachers are the two most important factors of network instruction activities. The interaction between them is an essential part of instruction. Teachers are the designer and organizer of web-based learning resources. In fact, even in the individual interaction process, learners are inevitably affected by the impact of teachers. Web-based learning resources have been infiltrated by the teachers' instruction intention and other important information. Certainly, we not only pay attention to those information included in the learning resources, but also will be more focus on the ability of teachers to provide effective learning support services for learners. Teachers will help students to identify that curriculum content is the information, skills, attitudes or values. Teachers will organize students to apply what they have learned including practice skills and knowledge. Teachers will organize formal or informal quizzes to find out whether the students make progress, thus helping students whether they need to change strategy. Finally, teachers also need to provide advice, support and encouragement for students, whose extent and nature depends on the education level of learners, educational philosophy of educational institutions, teachers' personality and social environment and other factors.

With the wide application of network technology in the information interaction between teacher and student, the exchange content may be more than the curriculum content itself, even with personalized trend. Many students may discuss other issues professionally with teachers, even privacy problems. This is the emotional support provided by the teacher. The specific interaction mode is shown in Fig.5.

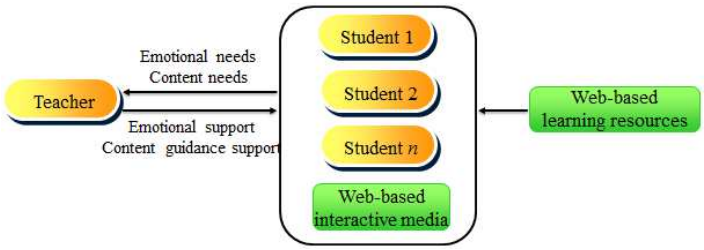

Fig.5. The interaction mode between students and teacher

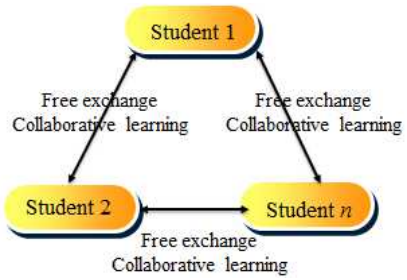

Fig.6. The interaction mode between student and student

The interaction mode between student and student. The interaction between the learner and the learner is a new dimension of network education. This interaction is the interaction between learners, which can occur between individual learners, as well as learners in the collective, and can or cannot have teachers to organize or participate in. In the course design including instruction objectives and content to train collective spirit, to explore community features and collaborative relationships, it is necessary to organize learners to gain collective interaction experience and to make it as a way of learning. At present, the main form of information interaction between student and student in the network learning includes free exchange, consisting of defining theme or non-defining theme, and collaborative learning, i.e. task-based cooperation. The free exchange can be individualized, and can be collective as well, in which the teacher is only as an equal participant and facilitator. A large number of studies show that the free exchange has a great role in promoting learning for students. The specific interaction mode is shown in Fig.6.

Media-based interaction mode analysis. We have analyzed network instruction interaction mode from the perspective of interactive subject mentioned above. This section will feature from media as called network interactive bridge to start with research on network instruction interaction mode. According to its functions, web-based media can be divided into synchronous media and asynchronous media. The synchronous media refers to interactive media with a consistent time, such as web chat room, videoconferencing system, audio conferencing system. The asynchronous media refers to interactive media with an inconsistent time, namely exists a delay in the information dissemination, for example e-mail, online forums, web pages. Correspondingly, media-based network interaction mode shown in Fig.7 can be divided into synchronous-media-based interactive mode and asynchronous-media-based interactive mode. Due to both of interactive mode above with its own advantages and disadvantages, the combination of two kinds of interactive mode will play a greater role in the actual network instruction process. The elements of media-based network interaction include learners, teachers and web-based synchronous/asynchronous media. Specially, asynchronous media is not only the exchange bridge of the other two elements, but also is a log carrier of exchange information.

Longitudinal Analysis of Network Instruction Interaction Based on Instruction Interaction Hierarchical Model

Network instruction interaction is a hierarchical model described in Fig.8, from operation interaction, information interaction to conceptual interaction, gradually from concrete to abstract, and also from junior to senior. The junior instruction interaction is the condition and foundation for the senior instruction interaction.

Operation interaction is the basis of information interaction, information interaction is the basis of conceptual interaction, and conceptual interaction is the highest level of interaction. Information interaction includes three kinds of interaction forms, such as interaction between student and

teacher, interaction between student and student, and interaction between student and learning resources. The interactive feature of media is the basis of all instruction interaction, because media is the platform and carrier of all the instructional interaction.

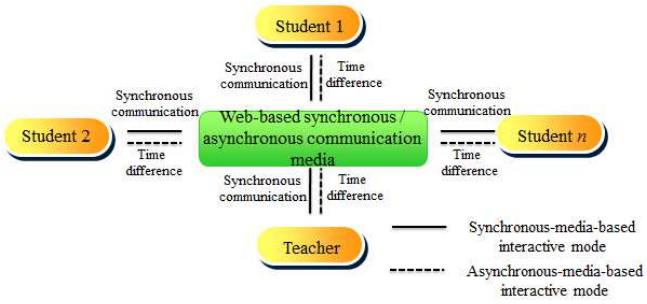

Fig.7. The interaction mode based on synchronous/asynchronous media

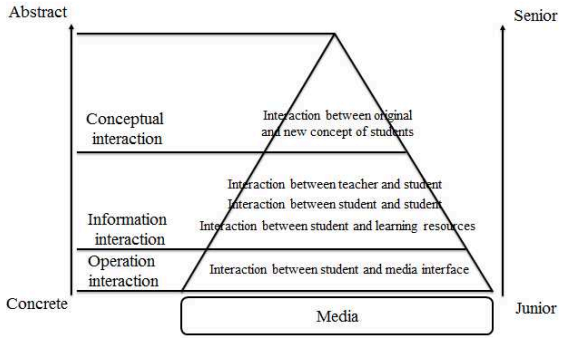

Fig.8. Instruction interaction hierarchical model

The Design of Network Instruction Interaction Mode

From the perspective of system theory, the interaction objects of network instruction platform can be divided into two elements, i.e. subject and object. The subject including teachers and students is the core part of the interactive system. The object including network instruction platform and those interactive means which act on the platform is a necessary condition for interactive system. From the perspective of teaching effectiveness, the interaction of network instruction platform can be regarded as the epitome of the network instructional system, which can also be regarded as the subject and object relational system. According to the interaction function established between the subject and object, the interaction of network instruction platform can be divided into the following three categories.

The interaction in navigation respect. The interaction in navigation respect refers to the network instruction platform how to present the teaching content and their relationships, including student subject how to browse and select information from the foreground and teacher subject how to control the structure and framework of instructional contents from the background and so on. Such kind of interaction is to enable students to master the learning content quickly including knowledge structure, learning paths and specific learning content through the foreground, and is to enable teachers to quickly generate network learning resources from background using clear navigation.

The interaction in feedback and reinforcement respect. The interaction in feedback and reinforcement respect refers to control mechanism between network instruction platform and the student subject. When students enter certain information, the system can be feedback response according to the input conditions. Feedback response may be dominant and may be recessive. The dominant response manifests that students through the user interface can see the response, such as test results feedback and learning feedback. The recessive response manifests that the system will respond to the results transmitted to the back-end database to be stored or processed, and students can not directly see these results because these results are not apparent directly on the user interface, such as learning process tracking, learning pace, control strategies of learning content and so on.

The interaction in functional operation respect. The interaction in functional operation respect refers to the network instruction platform to provide methods and interface interaction techniques for student subject using the platform, in order to enable students to familiarize the basic network learning methods and techniques, to reduce the difficulty of computer operation for students and to enhance friendly interactive interface. For example, platform provides help module, interactive downloads for special teaching resource player plug, etc.

The overall architecture design of the network instruction platform is shown as Fig.9.

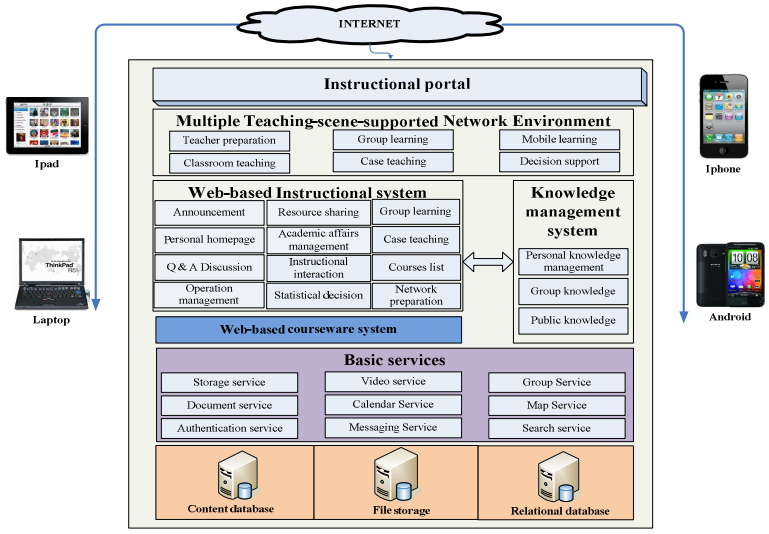

Fig.9. The architecture design of network instruction platform

Conclusion

Due to the spatiotemporal separation of teachers and students in the network instruction, web-based instruction interaction is essentially different from the face to face interaction in a traditional classroom. The learning quality of learns on the Internet depends largely on their level of interaction with the online courses. The interaction of network instruction platform is the main way to connect instructional contents, students and teachers, and also is the main channel for the implementation of the teaching process. In the research and design of interaction of network instruction platform, we use system approach, from the perspective of the relationship between subjective and objective comprehensively analyze design strategies of interaction including navigation, feedback and reinforcement, and functional operation, and fully consider characteristics of teachers and students, learning resource type, network own characteristics and other influence factors. Therefore, we rationally apply interactive means and methods of network instruction platform to improve the effectiveness of network instruction.

Keywords: TCP; Congestion Control; Sliding Window; Algorithm

Abstract. With the rapid development of information society, the number of information data transmitting in the Internet is growing quickly, so congestion control becomes very important and it is a hot research field on the Internet now. In this paper, the sliding window, reasons and TCP algorithms of congestion control such as slow start, congestion avoidance, fast retransmit and fast recovery are discussed. Different TCP versions about congestion control are studied and analyzed. As a result, improvements on the congestion control algorithm and the research is still an important topic in the study of Internet congestion control.

Introduction

Most of the work for congestion control is done by TCP protocol, which contains some network congestion control algorithms. The reliability and stability of the Internet today is closely connected with TCP congestion control mechanism, and the success of TCP owes to its stable congestion control mechanism. Along with more and more applications and continuous development of technology, it is very difficult to meet the requirements of quality of service (QoS) relying on terminal systems' strategy and algorithm only. Relevant network technology gradually turns to the middle network nodes such as routers, by enhancing their functions to realize what the end-to-end technology cannot achieve, so as to realize effective congestion control, maintaining good performance of the network.

The original TCP has only flow control and doesn't have congestion control. The receiver uses TCP header to notify it's receiving capacity to the sender. Such control mechanism only considers the receiver's capacity and doesn't consider network transmission ability, causing network breakdown (Congestion Collapse).

Reasons of congestion

If the transport entities on many machines send too many packets into the network too quickly, the network will become congested, with performance degraded as packets are delayed and dropped. This situation is called congestion [1]. Congestion is a state of continuous overload of network, since the demand for network resources is over its inherent capacity, which is the most important reason of congestion. There are some other reasons of congestion, mainly including: 1) Relative insufficient buffer space. Mainly on the router, while increasing the buffer space sometimes can relieve congestion, but sometimes it will aggravate congestion. 2) Insufficient bandwidth for high rate data stream. Low-speed link can also cause congestion on high rate data stream input. 3) Link mismatch to the processing speed of CPU, causing weak processing capacity and congestion.

Link capacity, buffering space in switching nodes, processors and so on, are the resources of the network. In a certain period of time, if the demand for available resources in the network is more than what it can provide, the network performance will be worse. If there are many resources leading to congestion at the same time, the performance of the network will degrade obviously. The network throughput will decline along with the increase of input load. Since the congestion is derived from the imbalance of the network resources and network traffic distribution, congestion will not be eliminated with the increase of network capacity.

Congestion control mechanisms of TCP

1. TCP's sliding window mechanism

Like many of the flow control protocols, TCP is also using the sliding window mechanism, but there are still some differences from other protocols, such as LLC, HDLC and x.25. Data receiving acknowledgement and data sending notice are processed separately. Every byte is assigned a sequence number. When the sender transmits message segment, each byte of the data gets a sequence number, using ($A = i, W = j$) message form to confirm data transmission. The specific meaning is as follows:

(1)If the sequence number of *i-1* has been confirmed, the sequence number of the following byte which is expected to receive is *i*;

(2) The receiver permits the other party to send *j* bytes of data (*j* is window size). The sequence number of those bytes is from *i* to *i + j-1*.

In TCP, the sending rate of data is determined by the slowest part among the hosts and other network nodes. The receiver needs some strategies to decide how many bytes the sender sends. A conservative method is permitting the sender to send message segments that the buffer space can just accommodate. Under the condition of bigger delay bandwidth, the receiving party can improve the throughput by advancing cache space.

2. Additive increase multiplicative decrease (AIMD) algorithm

TCP is the most widely used end-to-end transport protocol on the Internet, and its congestion control mechanisms are mainly based on additive increase multiplicative decrease (AIMD) algorithm. The algorithm defines three window variables:

(1) Congestion window (*cwnd*): it limits the maximum number of data transmitted by the sender in a timeframe, which is a sender-side limit on the amount of data the sender can transmit into the network before receiving an acknowledgment (ACK).

(2)Advertised window (*awnd*): after the connection is established between the receiver and the sender, the receiver notify the sender its maximum receiving rate, which is a receiver-side limit on the amount of outstanding data.

(3) Effective window (*win*) : the actual window size that the sender sends data. The sender's actual (usable) window *win* is then written as the minimum of the receiver's advertised window *awnd* and the congestion window:

$$win = \min(cwnd, awnd)$$ [2].

The working process of AIMD can be divided into two steps:

(1)Once the sender receives an ACK for the receiving confirmation, congestion window increases according to the formula $cwnd = cwnd + mss * (mss / cwnd)$, in which *mss* is the maximum message length. It means that if the packets sent by the sender are confirmed in the recent round-trip time (RTT), the sender's *cwnd* add 1, namely Additive Increase idea.

(2)When a timeout occurs at the data transmission, TCP considers congestion appearing on the link, and begins to decrease data sending rate. Once a timeout occurs, the sender will recalculate the value of the congestion window, formula is as follows:

$$cwnd = cwnd / 2,$$

This thought is the congestion window decreases to a half of the original *cwnd*, namely the Multiplicative Decrease idea.

Four congestion control stages of TCP

TCP congestion control can be divided into four stages of slow start, congestion avoidance, fast retransmit and fast recovery, reflecting the basic idea of TCP congestion control.

(1) Slow Start

When starting a connection old TCP sends many packets to the network, lots of packets may run out of buffer space of routers, resulting in the throughput of TCP connection fall sharply. The algorithm to avoid is slow start.

When the connection has just established, or a timeout occurs, the network is at the stage of slow start. Congestion window has been initialized to a packet size (a packet with default size of 536 or 512 byte). The sender is allowed to send only one message. When a message receives an ACK from the receiving end, *cwnd* adds 1, which is to add a message segment to send. Obviously, the *cwnd* will grow exponentially depending on the RTT (an exponential growth: 1, 2, 4, 8...). Thus the the amount of data sent into the network will increase sharply.

By using slow start TCP can prevent sending too much data and causing data loss and network congestion when starting a new connection. At the same time, because the *cwnd* actually grows exponentially, the problem of throughput increasing slowly caused by the pure AIMD algorithm is avoided.

Infinite growth of *cwnd* will lead to network congestion, so a state variable should be introduced: slow start threshold *ssthresh*.

When *cwnd* < *ssthresh,* TCP implements slow start algorithm, *cwnd grows* exponentially with RTT;

When *cwnd* > *ssthresh,*, congestion avoidance algorithm is adopted to slow the growth of the *cwnd* [3].

(2) Congestion Avoidance

When a timeout occurs or three same ACK frames are received, congestion happens. At this time the network enters a stage of congestion avoidance.

At congestion avoidance phase, when TCP detects congestion is happening, it does not reset *cwnd = 1* directly and apply slow start method. Because it takes a long time to recover in case of congestion and *cwnd* exponential growth in slow start algorithm appears radical, it is likely to increase the congestion. Therefore, a relatively more conservative regulatory mechanism is used to change *awnd* growth way, makeing it become linear growth from exponential growth at this stage, the specific process is as follows:

The slow start threshold *ssthresh* is set to a half of the current *cwnd*, namely the *ssthresh = cwnd / 2;*

When a timeout occurs, setting *cwnd = 1*, TCP implements slow start algorithm under the condition of *cwnd*< ssthresh;

Under the condition of *awnd* ≥ ssthresh, congestion avoidance algorithm is implemented. After receiving each of ACK, *cwnd* add only 1 / *cwnd* packets, making *cwnd* grow linearly with RTT.

(3)Fast Retransmit and Fast Recovery

When a timeout occurs at the congestion avoidance phase, *cwnd* is reset to 1, entering the slow start stage. This will lead to decrease send window size excessively and reduce the throughput of TCP connection. In order to improve the performance of TCP, the fast retransmit and fast recovery mechanisms are introduced.

At the fast retransmit phase, when the sender received 3 or more duplicate ACKs, it judges that the packets are dropped. The *ssthresh* is set to one half of the current *cwnd* (i.e. *ssthresh = awnd/2)*, and the dropped packets are retransmitted, entering the stage of fast recovery.

At the fast recovery phase, when the sender receives each of a repetitive ACK, the *cwnd* adds 1; If the sender receives a different ACK, *cwnd = ssthresh*, the network transfers to congestion avoidance stage; When a retransmission timeout occurs, *ssthresh = cwnd / 2, cwnd = 1,* the network enters the stage of slow start.

Fast retransmit and fast recovery mechanisms avoid entering slow start stage directly while a timeout occurs, which improves the performance of TCP and throughput to a great extent.

Analysis and comparison of TCP congestion control algorithms

Van Jacobson pointed out the shortages of TCP in network congestion control in 1988. He put forward the "Slow Start" algorithm and "Congestion Avoidance" algorithm. TCP Reno version in 1990 added the "Fast Retransmit" algorithm and "Fast Recovery" algorithm, which avoid the phenomenon of excessive reducing send window size because the slow start is implemented when

the congestion is not severe. TCP congestion control is made up of the above four core parts. Improved TCP versions have been emerged in recent years, such as New - Reno, SACK, Vegas and so on, each of which has advantages and disadvantages.

(1) TCP Tahoe algorithm

TCP Tahoe is the version joined Van Jacobson's algorithm of slow start, congestion avoidance, fast retransmit in 1988 after 4.3 BSD or similar TCP implementations[4]. The core idea of Tahoe algorithm is that the *cwnd* rapidly approaching available channel capacity in exponential growth way, then slowly close to equilibrium. It includes three basic congestion control algorithm: slow start, congestion avoidance, fast retransmit. The shortcomings of Tahoe lie in low efficient network bandwidth utilization and long delay while transferring from slow start to fast retransmit.

(2) TCP Reno algorithm

Aiming at the shortcomings of the algorithm of Tahoe, improved algorithm of Reno was proposed. The improvements mainly includes two aspects: One is, the algorithm directly enters congestion avoidance after receiving three consecutive duplicate ACKs without entering low start; The second is, fast retransmit and fast recovery mechanisms were added. Reno algorithm has become the mainstream in TCP source algorithms for its simplicity, efficiency and robustness, being used widely. But Reno algorithm has also performance problems under the condition of losing multiple segments in the same window. The dropped messages will make TCP implement fast retransmit and fast recovery, and the *cwnd* and *ssthresh* will be halved for many times, greatly reducing the throughput.

(3) TCP New - Reno algorithm

New - Reno added fast recovery algorithm into Reno, it takes into account that multiple packets dropped within a send window of data at the same time. In Reno algorithm, the sender quits from fast recovery after receiving a non-duplicate reply. However, in New - Reno, only when all the packets are replied does the sender quit from fast recovery. It is very easy to realize New Reno, as long as modifying TCP sender’s implementation code.

(4) TCP Sack algorithm

SACK algorithm was improved to solve the problem of multiple packets dropped in a window of data for Reno algorithm. A variable of SACK pipe is defined to estimate the numbers of packets appearing on routers. The TCP receiver sends SACK packets to notify the sender it’s data receiving, so that the sender knows exactly what data is correctly received, so as to avoid unnecessary retransmission, reduce delay and improve the network throughput. But the realization of the SACK algorithm need to modify TCP sender and the receiver implementation code, increasing the complexity of TCP, therefore it is not easy for large-scale of applications [5].

(5) TCP Vegas algorithm

Vegas is different from the above algorithms, it adjusts sending rate based on the change of RTT as congestion signal, by monitoring the change of RTT to change the size of the *cwnd*. Since Vegas use RTT to determine the available network bandwidth, it can well predict the usage of network bandwidth with good fairness and efficiency. However, it is some unfair for Vegas compete bandwidth with other algorithms, thus it fails to use widely on the Internet and needs to improve continuously.

Conclusions

With the increasing of network scale, the most efficient way to improve congestion control is introducing router queue management congestion control algorithm based on the traditional end-to-end TCP congestion control, which will improve the congestion control on the network. On the basis of the existing congestion control mechanism, an effective congestion control algorithm will bring huge advantage for the development of the Internet.

Research on Forensics Method based on Log on SaaS

Gang Zeng

Police Information Department, Liaoning Police Academy, Dalian, China

Email:dlzenggang@126.com

Keywords: log; digital forensics; SaaS; user behavior sequence

Abstract.Cloud computing is getting more and more attention from the information and communication technologies industry recently, security issues is becoming more important. Forensics technology on cloud computing is becoming a researched focus. In this paper, we discuss the impact and challenges to digital forensics, finally we present the improved measure of log and forensics system based on logs on SaaS.

Introduction

Cloud computing is getting more and more attention from the information and communication technologies industry recently, because of its key characteristics: agility, low cost in using, device and location independence, Virtualization, Reliability, scalability and etc. It has three delivery model: Infrastructure as Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS). Now we use cloud computing universally, but there is also attack in cloud computing environment, forensics is the effective way to deal with the security question.

It is very difficult to collect evident in cloud computing environment, but we can do some work by logs, logs exist anywhere in cloud computing, it records evidence with security. In this paper, we mainly discuss logs, firstly, we introduce digital forensics and the impact and challenges to traditional digital forensics in cloud computing environment; In section II, we discuss Log System and Improvement; In section III, we design a system, which collect logs from cloud computing, then analyze it.

Digital Forensics and the impact and challenges

1.1 Digital Forensics

Digital forensics is a branch of forensic science encompassing the recovery and investigation of material found in digital devices, often in relation to computer crime. It was originally used as a synonym for computer forensics but has been expanded to cover investigation of all devices capable of storing digital data. Therefore, it is called digital forensics[1].

A digital forensics investigation commonly consists of 4 procedures: identification, evidence collection, analysis, and reporting. Acquisition involves creating an exact sector level duplicate of the media, often using a write blocking device to prevent modification of the original data. Both acquired image and original media are hashed (using SHA-1 or MD5) and the values are compared to verify the copy's accuracy.

The evidence is analyzed to reconstruct events or actions, and to reach conclusions. When an investigation is completed, the data is presented, usually in the form of a written report in lay persons' terms.

1.2 Impact and Challenges to traditional digital forensics

With the development of cloud computing, it has been found that traditional digital forensics is not suitable for cloud computing, This is the methods of traditional digital forensics: create an image of the media seized from the crime scene, and at the same time the data mustn't be modified, then analyze on the image to find evidence. But it is realistic in cloud computing environment, because it meets challenges coming from cloud computing.

The first challenge is multi-tenancy and resource sharing. Many users use the same cloud, who uses it, when, where is it being used? What the users have done? To answer these questions, it is

easier in past, because the environment was simple than now, but it is difficult in cloud computing environment which is multi-tenancy and resource sharing.

The second challenge is that Cloud computing is more vulnerable to attack. Users access the cloud computing by internet, new attack methods to cloud computing keep popping up excepting the original attack mode, some attacks use the security vulnerabilities of cloud computing, other attacks are deformation of the traditional methods of attack. The following are some of the attacks:

- Wrapping Attack
- Malware-Injection Attack
- Flooding Attack
- Browser Attack
- Insecure Interfaces and APIs
- Malicious administrators
- Data Stealing
- Data Leakage

The third challenge come from Other technical matters .

Traditional forensics is impotent in cloud computing environment, in IaaS model, we may get a complete image of a virtual machine, but we don't know that the evidence we focused on is in which one of all virtual machines, in PaaS or SaaS model, we can't get a complete image of hard disk.

Cloud computing is running uninterruptedly, if the cloud is shutdown, the data that can be relevant to an investigation may be lost, and parallel or unrelated services may be interrupted, This is fatal for Business Companies, is not allowed[2][3][4].

Challenges come from log of cloud computing at the same time. Log is recorded in different format in different environment, and different content is record by different applications. Now the problem that we have to solve is where we can find the log, how to analyze them, what does log mean? How to link them together? What is more serious is that non existence of logs and absence of critical information in logs.

Log System and Improvement

2.1 present situation of log analysis

We often hear the term called "log", what does the log contain, Why we study it? Log has recorded some important information: who used the cloud, when and where did he login(IP), which service did he use, when did he logout? These information is very helpful for tracking the attack.

Log is important , but our understanding about the log is one-sided, when it comes to log, it is deemed the system log by a lot of people. The log that we discus, Includes not only the cloud server log, including the client log, cloud service providers operating billing log; also includes network equipment log, includes log that is beneficial to digital forensics[5].

Now, many questions exists in log analysis, there is redundant information, even self-contradictory records in the log, these information is useless for us to collect evidence.

By the log, we can find the time when the user use cloud, particular IP that user accessed, services that users have used. We can find the relationship between the multiple log events by Statistic and analysis of log and mining, and then find the cloud service mode and the user usage mode, find out the clues and evidence of the cases by Analysis on user behavior pattern. But analysis of the log is not deep enough, correlation degree between evidences is not enough too.

2.2 Improvement of log system

It is because of the above reason, we propose an improved measure for log system. What problem the improved measure can solve, what principles should be followed in log management, what is recorded in log, what is the format of log, where log stored is safe, these problem is very important, now we discuss these problems.

First of all, the basic principles of log management guide our actions, it guides us what should be done and what should not be done. The principles are as follows:

- Log is recorded when and where we need it.
- Logs should be centrally managed.
- Content of log is what we need.
- Format of log can be understood by us.

Now many system do not record logs because of performance or storage capacity, When an event occurs, no logs is available for analysis, therefore, we should record logs as much as possible.

Many systems do not record logs for performance or storage capacity, so we propose a solution of centralized log management. Logs are transferred from the sources to a central log server, the application server need not high capability and big storage capacity any more.at the same time, logs is more safety than on the application server. When logs are transferred to log server, we should solve the following questions:

- Reliable transport protocol
- How to encrypt the log
- How to compress log to save bandwidth.

Our focus is what should be recorded in the log, This is directly related to what we can get in the future. At a minimum, the following fields need to be present in every log record: user_id, session_id, client_ip, application, activity, timestamp, Severity, Reason, Categorization. These fields help answer the questions: when, what, who, and why.

The format of log is one of the challenges to digital forensics, the format that the record is made up key-value pairs, it is suitable for MapReduce mode, and is based on standards work and the study of many existing logging standards.

user_id=zhangsan_ram_010,session_id=05BaswoGGQgQQDVDG3IEEEEED,
client_ip=1.2.3.4,object=sales, action=insert, status=failure,
severity=ERROR,reason= syntax error,time=2014-05-3 16:25:47.123231PDT.

Log Analysis System Based On Hadoop

3.1 Structure of the System

The log of cloud computing is very important, and includes helpful evidence for digital forensics, but the cloud computing is multi-tenancy and Resource Sharing, and many tasks are running on it, so massive logs is stored in the cloud, their format is different. It is very difficult to analyzing on log by traditional methods, we designed a forensics system based on Hadoop for SaaS.

The forensics system is composed of the following function modules: evidence collection module, evidence processing/analysis module, reporting module. The evidence collection module is responsible for the collection of logs from the target cloud computing, it is a plus-in or an application, and easy to deploy. The log processing module is the core module of the system, it includes two functions: pre-processing and analyzing. Reporting module has a graphic user interface, users can execute all kinds of commands includes querying data, cluster analysis, association analysis, etc.

The structure of system consists of the following layers[5]:

1.Hadoop cluster layer, It consists of many virtual machines, Hadoop service is been installed in the virtual machines.

2.Distributed file system layer, we use HDFS file system, the massive log files will be stored in it, its duplicate strategy and load balancing strategies can provide reliable service.

3.Database layer, it provides data storage service, by the reasonable arrangement of the primary key and indexes, it provides data access for the upper layer. We use HBase as database, It can meet the high concurrency, high scalability requirements. All log data is stored in HBase.

4.Business processing layer, a variety of business logic is performed here, includes query, analysis, association and so on, these business processing can be transformed into Map/Reduce model.

5.user interface layer, the interface is is a graphical user interface, simplified operation.

3.2 Pre-processing of log

1. The module of log collection, we use the open source components for log collection, it can real-time or periodically collect log files from SaaS system.

2. The module of data-processing, As the number of users in SaaS systems is very large, the log is massive and miscellaneous, it often contains noise, missing data and inconsistent data, in order to improve the quality of log data, and improve the quality of the data analysis, improve the efficiency of log mining, the data processing is needed.it includes：

Data cleaning：to remove duplicate data, inconsistent data, impossible or incorrect data.

Data transformation: to transform the log on a system to the data that can be identified on another system, to transform log into the model that is easy to mine, transformation methods include clustering, normalizing, etc.

3.3 Analyzing of log

Combined with the characteristics of SaaS, we adopted the analysis method based on user behavior pattern.

1.The log collection：We can collect log information in the key points of the system by the log collection module. The key points include SaaS application system, operation system, the network device, the safety system, etc.

2. Users' behavior modeling：The traditional method of behavior modeling is based on the statistical results，Including the frequency of access, access time，etc. This method describes the behavior patterns statically，and these descriptions lack the ability to describe the behavior of semantic information. Aiming at this problem, This paper proposes a behavior element model of log based on Metadata.

According to the characteristics of user behavior, behavior pattern can be divided into three layers: the key point, activity and the session.

The key point is the users access Location in the system, it includes: Function modules in SaaS and equipment where users have accessed; User location, etc. we can use the following tuple to describe it[6].

(user_id, request_id, Time, Delay, Stateset);

Activity not only describe the semantic information of user access sequence, such as keywords, links, abstract, and corresponding operations, such as search, login, add, modify, delete , logout, etc.

(Userid, Activity_id, ActivityNane, Time, Delay, StateSet)

A session is a series of activities to achieve specific objectives, and it is described by the following tuple,

(User_id, Session_id, Time, Delay, StateSet, Activities)

Algorithmic thought：

This algorithm uses the depth first search strategy, checks prefix subsequence frequently, divide the corresponding postfix subsequences into projection sequence database according to the length, these postfix are mutually independent and does not affect reciprocally. Then constantly recursion, generate multiple smaller sequence databases from sequence database, finally, digging one by one in the projection database.

User behavior pattern clustering

According to the user access behavior, the user behavior is divided into login, query, add, modify, delete, logout, calculation, report, etc. Along with the increase of the using time, the user behavior pattern must be integrated a variety of behavior. According to changes of behavior sequence model on a time axis, by sequence similarity calculation method, finally cluster on behavior sequence model[7].

Conclusion

This paper analyzes first the characteristics of cloud computing and challenges to cloud computing forensics, then proposes the improved method for SaaS system log, finally proposes forensics method on SaaS based on user behavior sequence model. But the forensics method needs changes in log system, this is the shortage of the method, and it is also the place to improve in the future.

Keywords: Algorithm Complexity; Neural Network; Weight Function; Orthogonal Approximation

Abstract. To describe the performances of a new kind of neural network, the complexity for training neural network using orthogonal weight functions is analysed. The full adders are used as the neurons of the neural networks, and the weight functions are orthogonal functions. We derive the relationships of the iteration time with the number of input dimensions, output dimensions and training patterns. Finally, some simulation examples verified the theoretical results obtained in this paper.

Introduction

Traditional neural network algorithms (such as BP or RBF) have some shortcomings such as local minima, slow convergence and initial sensitivity, these shortcomings can impede the development and application of neural networks [1]. To overcome those shortcomings mentioned above, Literature [2] proposed a new kind of neural network's learning algorithm, named as weight function neural networks, which makes the training weights as functions of the input samples called weight functions, rather than a set of constants used in conventional algorithm.

Based on spline weight function neural networks, this article introduces the topology of first category orthogonal weight function neural network, then gives the algorithm to solve the orthogonal weight functions and analyses its time complexity, finally verifies the theoretical results through MATLAB simulation experiments.

First Category Orthogonal Function Neural Network Topology

Literature [2] gives the topologies of first category and second category spline weight function neural network. Topology of first category orthogonal weight function neural network with m-dimensional input layer and n-dimensional output layer in this article is shown below:

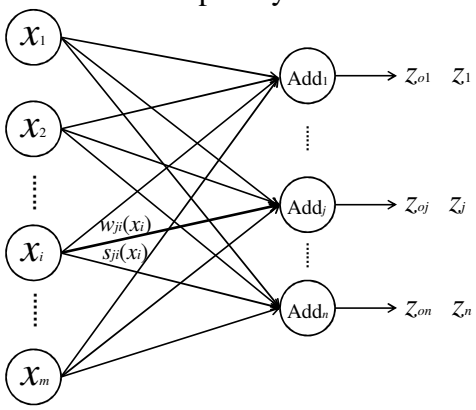

Fig. 1 First category orthogonal weight function neural network with *m* input layer and one output layer.

The network has *m* input nodes that directly connect with output nodes which are adders by weighting functions $w_{ji}(x_i)$ i=1,2,…,m; j=1,2,…,n. Each component z_j (j=1,2,…,n) of the network output $\boldsymbol{z}$ is the sum of all input samples' weight function value, namely

$$z_j = \sum_{i=1}^{m} w_{ji}(x_i) \ \ (i = 1,2,...,m; \quad j = 1,2,...,n) \tag{1}$$

The First Category Orthogonal Weight Function Neural Network Training Algorithm

Literature [2] gives the first category spline weight function neural network training algorithms. According to theories in literature [2] we give the training algorithm for first category orthogonal weight function neural network. Suppose there are N training samples, input for i-th node can be expresses as a vector $x_i = (x_{i0}, x_{i1}, \cdots x_{i(N-1)})$, target vector can be expressed as $z = (z_0, z_1, \cdots, z_{N-1})$, where z_j (j=0,1,$\cdots$,N-1) is a n-dimensional column vector. Orthogonal weight function neural network algorithm is to solve the orthogonal functions $S_{ji}(x_i)$. The neural network training interpolation points are as follows:

$$\mathbf{Ip}_i = \left\{ (x_{i0}, \eta_i z_0), (x_{i1}, \eta_i z_1), \cdots, (x_{i(N-1)}, \eta_i z_{N-1}) \right\} \tag{2}$$

According to least-squares fitting theory [3], weight functions can be written as:

$$S(x) = a_0\varphi_0(x) + a_1\varphi_1(x) + \cdots + a_n\varphi_n(x) \tag{3}$$

Least-squares fit is defined by minimizing the square error of the data and to find the best match function, using the least squares method can be easy to obtain unknown data, making the square error between the obtained data obtained with the actual data is minimized. Using mathematical language can be describes as:

$$\|\boldsymbol{\delta}\|_2^2 = \sum_{i=0}^{m} w(x_i)\left(S(x_i) - f(x_i)^2\right) \tag{4}$$

Orthogonal function means for a function set $\phi_1(x), \phi_2(x), \cdots, \phi_r(x) \in [a,b]$, any two functions satisfies $a_i = (f, \phi_i) = \int_a^b f(x)\phi_i(x)\mathrm{d}x, i = 1,2,\ldots$. When using orthogonal polynomials $g_k(x)$ (k=0,1,$\cdots$,l) to solve the least squares fit polynomial as the neural network weight functions, the resulting $S^*(x)$ is called orthogonal weight function.

We use Chebyshev orthogonal polynomial $\{g_i(x)\}_{i=0}^{l} \subset H_l$ and $\rho(x) = 1/\sqrt{1-x^2}$ to solve weight functions $S^*(x)$ in the interval C[-1,1], then

$$S_l(x) = \sum_{k=0}^{l} a_k g_k(x) \tag{5}$$

where

$$a_k^* = \frac{(f, \varphi_k)}{(\varphi_k, \varphi_k)} = \frac{\sum_{i=0}^{m} \omega(x_i) f(x_i) \varphi_k(x_i)}{\sum_{i=0}^{m} \omega(x_i) \varphi_k^2(x_i)}, \quad (k = 0,1,\cdots,n) \tag{6}$$

Algorithm Complexity Analysis of the First Category Orthogonal Weight Function Neural Network

For the structure shown in Fig. 1, give the algorithm pseudo-code.

Algorithm Input: Point out to be fit ($\boldsymbol{x}$,$\boldsymbol{z}$) ($\boldsymbol{x}$=[x_1,x_2,…,x_N],$\boldsymbol{z}$=[z_1,z_2,…,z_N]), orthogonal polynomials weight $\rho(x)$, maximum permissible error *mpe*, maximum order of fit *Max_n*;

Algorithm Output: Orthogonal basis function coefficients.

Algorithm Steps:

Step1 set $\varphi_0(x) = 1$; $a_0 = (\varphi_0, y)/(\varphi_0, y0)$; $P(x) = a_0\varphi_0(x)$; $err = (y, y) - a_0(\varphi_0, y)$;

Step2 set $a_1 = (x\varphi_0, \varphi_0)/(\varphi_0, \varphi_0)$; $\varphi_0(x) = (x - a_1)\varphi_0(x)$;

Step3 set $k = 1$;

Step4 while (($k \le Max_n$) && ($|err| \ge mpe$))

Step5 k++;
Step6 $a_k = (x\varphi_1, \varphi_1) / (\varphi_1, \varphi_1)$; $\beta_{k-1} = (\varphi_1, \varphi_1) / (\varphi_0, \varphi_0)$; $\varphi_2(x) = (x - a_k)\varphi_1(x) - \beta_{k-1}\varphi_0(x)$;
$a_k = (\varphi_2, y) / (\varphi_2, \varphi_2)$; $P(x) += a_k\varphi_2(x)$; $err -= a_k(\varphi_2, y)$;
Step7 set $\varphi_0(x) = \varphi_1(x)$; $\varphi_1(x) = \varphi_2(x)$;
end;
Step8 output( ); end.

Where in, solving $(\varphi_j, \varphi_k) = \sum_{i=0}^{N} \omega(x_i)\varphi_j(x_i)\varphi_k(x_i)$ need to call the child algorithm 2:

Step1 set $(\varphi_j, \varphi_k) = 0$;
Step2 for ($i = 0$; i != N; i++)
for ($k = 2$; k! = N-1; k++)
$\varphi_0(x_i) = 1$; $\varphi_1(x_i) = x_i$; $\varphi_k(x_i) = [(2k-1)\varphi_{k-1}(x_i) - (k-1)\varphi_{k-2}(x_i)] / k$;
end;
end;
$(\varphi_j, \varphi_k) += \omega(x_i)\varphi_j(x_i)\varphi_k(x_i)$;
Step3 output((φ_j, φ_k)); end;

Main algorithm include a *while* loop which contains several (φ_j, φ_k), to solve (φ_j, φ_k) need to call algorithm 2 that have a *for* loop which solve k-order orthogonal polynomials and should be execute k times. Analysis of the above algorithm time complexity [4] [5] we find in the worst case time complexity is

$$T(N) = O(N^2 \log N) \tag{7}$$

Where N is the number of training samples. For m input, n output first class orthogonal weight function neural network, need to solve each weight function connected input and output neurons, the time complexity is

$$T(m, n, N) = mnO(N^2 \log N) \tag{8}$$

Experimental Methods and Results

Experiment I:

Select appropriate network topology: input layer with two nodes and output layer with two nodes; objective function $x_1^2 + x_2^2$; learning curve: $x_1 = f_1(t) = t$, $x_1 = f_1(t) = t$; number of samples N with 100, 200, ..., 1200 ; multiplication factor takes equal distribution. Count the training times of first category orthogonal weight function neural network under different training numbers.

Experiment II:

Select appropriate network topology: input layer with 2,4,6,8, ... 30 nodes; output layer with two nodes; objective function: $x_1^2 + x_2^2$, $x_1^2 + x_2^2 + x_3^2 + x_4^2$ ..., $x_1^2 + x_2^2 + \cdots + x_{30}^2$; learning curve: $x_1 = f_1(t) = t$, ..., $x_{30} = f_{30}(t) = t$; number of samples N with 400; multiplication factor takes equal distribution. Count the training times of first category orthogonal weight function neural network under different input layers.

Experiment III:

Select appropriate network topology: input layer with two nodes; output layer with 2,4,6, ..., 30 nodes; objective functions of each output layer depends on the number of nodes; each input layer node with objective function $x_1^2 + x_2^2$; Learning curve: $x_1 = f_1(t) = t$ $x_2 = f_2(t) = t$. number of samples N with 400; multiplication factor takes equal distribution. Count the training times of first category orthogonal weight function neural network under different output layers.

Experiment results:

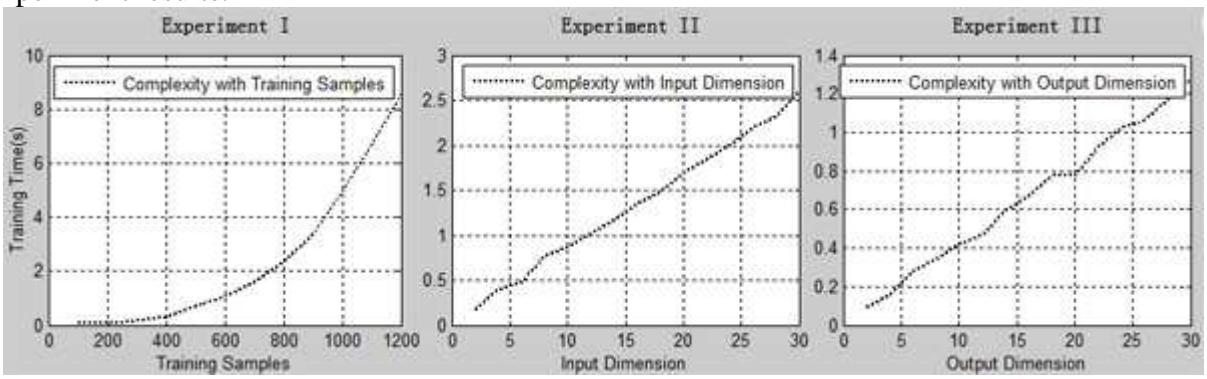

Fig. 2 The first category orthogonal weight function neural network algorithm on the number of sample complexity of the training experiment

Experimental Analysis

Experimental results show that the first class to see the complexity and number of samples right orthogonal function neural network algorithm in line with the curve of a quadratic function, and the input and output dimension linear relationship. As can be seen from these three experiments the time complexity of the first class of orthogonal function neural network algorithm right in line with the conclusions previously deduced: $mnO(N^2 \log N)$.

Summary and Conclusions

This paper first introduces the right of the first class of orthogonal function neural network topology and training algorithm; then according to the algorithm complexity of knowledge, a key step in the analysis of network training the number of operations to derive the first class of orthogonal function neural network training right time complexity. Finally, the time complexity of the algorithm to verify the theoretical training results of the first class of orthogonal function neural network right through the experimental accuracy, the simulation results show that the right of the first class of orthogonal function neural network has a faster learning and training capabilities, and its training time complexity degree and the number of training samples, the input layer and output layer nodes nodes about which the input samples was proportional to the square of the relationship, with the input layer nodes and output layer nodes is linear.

Keywords: ultra-large-scale system;Software Crowdsourcing;Process management

Abstract. Software Crowdsourcing development model shows the increasingly strong advantage in solving the development of ultra large scale system, mode of development of this new software development process chang to mass, openness and community. At the same time, Software Crowdsourcing development process also reflects the strong competitive, crowdsourcing software development mode is a periodical process of releasing requirement-bidding competition-software review.In order to promote the community members to collaborate, compete and develop, and to improve the software development efficiency and quality,This paper discusses the group in the process of Software Crowdsourcing development, reward and remuneration of reputation and ranking, corporate governance.thus,we can Improve process management, improve the quality and efficiency of software development.

Introduction

The ultra-large-scale system has unprecedented complexity, variability and uncertainty, bringing huge challenge on traditional software engineering method. The ever-increasing Software Crowdsourcing practices, for example App Store of Apple Inc and Android Market of Google Inc, have revealed feasible program on solution of ultra-large-scale system structure problem. These new software engineering practices embody brand new software development mode: from elite researchers to public researchers, from closed and planned software development to opened and competitive software development, from workshop development environment to community development environment. In the whole ultra-large-scale system ecological environments of technology, the user will play a more and more important role.

Crowdsourcing software development mode

The basic software element in the ultra-large-scale system is defined as crowdsourcing software in this article, that is, the crowdsourcing software is the basic software entity in crowdsourcing software development method. During the crowdsourcing software development process, the basic crowdsourcing software development mode is a periodical process of releasing requirement-bidding competition-software review (as shown in Fig.1). Once the end-user proposes a specific requirement for the system, he may achieve it according to the following steps. Firstly, he can explain the specific requirement in natural language, and release it in the crowdsourcing software environment, and then ask for solutions from developers of the whole community. His requirement will be converted to design program by community members, and the best design program will be selected by collective review and prioritizing. Secondly, the winning program will be published to community members, and members with competence and development technology will be selected to participate in development competition. Finally, the created software entity will be performed collective review and user group trial, and each user can perform review and evaluation on each aspect of the software entity, and the related trial report will be generated. A new round of crowdsourcing software designing-realizing-testing and application will be performed according to review and trial result, and further improvement on the crowdsourcing software will be performed.

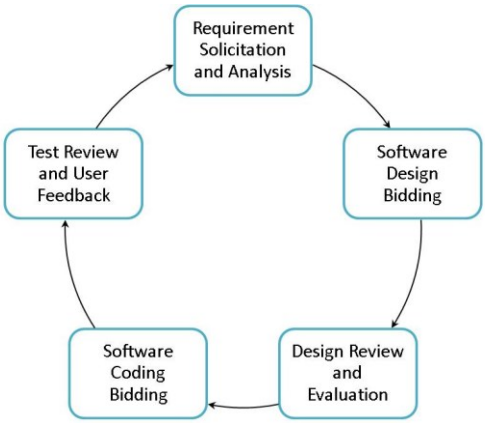

Fig.1 Crowdsourcing software development process

The above crowdsourcing software development process usually shows very strong competitive characteristic, similar to the contribution and appointment process in high level academic conference. Different from classical software development process, the crowdsourcing software task will not be assigned to a appointed developer in the company or epibolic contract engaged developer. On contrast, the crowdsourcing software task criterion containing technical requirements, development schedule and accomplishment reward will be released to the whole community in an open and transparent form, to admit the best by competition. The community members who are interested in the crowdsourcing software development task will accept the released task, set out to the coding work for the crowdsourcing software, and then submit their development results to the community review committee. The committee is responsible for the evaluation on their results and the selection of the best work as well as its developer. All the crowdsourcing software entities need to pass the competitive process and be designed and developed, and then pass the social test and integration. Similarly, the test and integration task should be organized and accomplished in a similar competitive method, to call upon the members with test and integration experience to participate. Therefore, the cooperative type competition mode is the main way to generate high quality software product in crowdsourcing software ecological environment. We can analogy the structure and evolutionary process of crowdsourcing software system to the compiling course of Wikipedia: each community member can contribute chapters or sentences in Wikipedia entry. And the entry is jointed and combined by basic character element and compound sentences and paragraphs in a recursion way.

Governance on crowdsourcing software development process

We need to perform scientific governance on crowdsourcing software development process, in order to promote the community members to collaborate, compete and develop, and to improve the software development efficiency and quality, and this involves in how to design a reward system to stimulate the crowd to participate in ultra-large-scale system development project; how to construct a ranking mechanism to ensure the crowdsourcing software developer have sufficient competence and quality to successfully accomplish the crowdsourcing software task; how to manage the social structure of the ultra-large-scale ecological system to regulate the development activity, balance the conflicts among project development cost, time schedule and project task complexity.

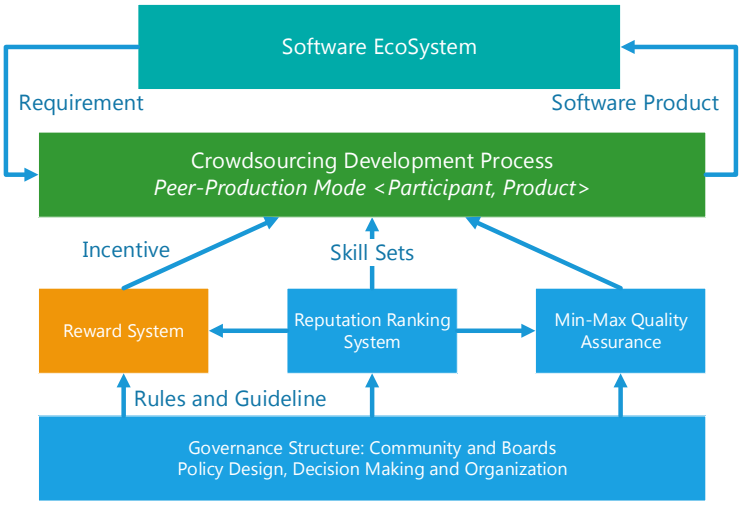

Fig.2 Crowdsourcing software engineering governance structure: reward mechanism, reputation mechanism and governance organization

Fig. 2 shows the basic governance structure of crowdsourcing software development, which consists of three sub-systems: reward system, reputation ranking system and top leading organization. The core of the overall governance structure is the relevance and interaction between grouped members. The community governance committee is the top leading organization, in charge of policy design, strategic decision making, structure planning and behavior standardizing. The governance committee has two necessary methods to cultivate healthy and energetic ecological system: the reward mechanism and the reputation mechanism. The reward mechanism provides incentiveness for crowdsourcing software, promotes them to participate in crowdsourcing software development; and the reputation mechanism provides quantitative basis for competence analysis of each community member, and also is the basis of reward mechanism.

3.1 Reward and compensation system

Crowdsourcing software development can't be separated with effective reward mechanism, and it is very important to attract wide range participation of community members to keep the vigor of crowdsourcing software platform. In traditional open source software community, the "Hacker" culture is usually known as the important factor to motivate people to participate in, because people wish to improve their coding competence and enjoy the challenging coding task[1]. Besides, people wish to make more contribution in the community, to acquire or enhance their popularity. Although these social reward mechanisms are still effective in crowdsourcing software development, it is far insufficient for them to mobilize people to accomplish complicated task such as ultra-large scale system. At the same time, the economic incentive method has powerful and effective power to promote community development activity[2]. According to the traditional economic theory, when the money reward is linked up with working performance, the rational workers will improve their working performance to improve product quality. This market-oriented incentive method can be adopted in the reward mechanism of crowdsourcing software community, to provide reasonable compensation for each crowdsourcing software task, and to encourage community developers to acquire the reward compensation by competitions.

3.2 Reputation and ranking system

The main functions of reputation system embody in two aspects: the first one is, to rank the intelligence and competence of participants, to guarantee the software product quality; the second one is, to promote the sufficient trust and positive interaction between the requester and the developer of the crowdsourcing software task. It is very difficult for the requester of the crowdsourcing software to find out skillful developer to accomplish the request, and exclude poor crowdsourcing software products. On the contrary, the ranking of the crowdsourcing software requestor will help the developer to select the task released by the requestor with high reputation, according to their history.

A reputation system can collect, release and aggregate the latest behavior and history of the requestor and the executor, and a ranking algorithm is adopted to perform quantitative score for

them. This kind of ranking method is usually established on basis of user evaluation and third party review. The main parts of online reputation mechanism include: crowdsourcing software task evaluation system, the accumulator and reputation engine fed back by crowdsourcing software. Firstly, the reputation ranking evaluation index can be subjective or objective. The quantitatively measured performance index of each community developer can embody his coding competence and the seriousness degree of executing the development task, for example, his successful submission number of times, the reward and corresponding user download rate of the crowdsourcing software entity created by him. And the information such as third party evaluation and user review can be analyzed as the crowdsourcing software entity quality and the basis of reputation subjective evaluation of crowdsourcing software task requestor. Secondly, all the collected information related to reputation are collated and sorted to establish detailed document for each community member, and to analyze their knowledge structure, competence degree and experience collection. Thirdly, the reputation engine can be used to synthesize the history and recent working performance, to give quantitative evaluation on the developer.

At present, the ranking algorithm research in crowdsourcing software calculating system is still in immature stage. It should be pointed out that the competition ranking research has been conducted for several decades. For example, the classical Elo ranking mode, which calculates the chess skill of each international chess player based on the statistic method, has been widely applied in various types of athletic contests. The improvement works on the basis of the mode enhance the accuracy of ranking algorithm and also introduce other statistic methods, for example: the player's performance fluctuation and Bayesian reasoning frame, to deal with the competition situation with multiple players[3][4]. We abstract the reputation system, apply them in crowdsourcing software engineering methodology, and define competitive software development principle.

Input: define a sequence S = { R1, R2, R3 }, in which each R is a six-tuple: (C, P, T, X, Y, Z), in which C is the criterion required by crowdsourcing software, P is the assemblage of participants, T is the assemblage of crowdsourcing software development tasks. The remaining functions: X, Y, Z defines ranking mechanism and reward system respectively.

X is the mapping function of crowdsourcing software product submission and its score in this round of the crowdsourcing software competition. Its definition is $X: P \times T \rightarrow Score$, in which P and T representatives the two assemblages of the participants and the tasks respectively. The score is a group of evaluation indexes, including: download counting, positive or negative evaluation from users as well as expert opinions of the review committee. Each participant can be ranked based on the score.

Y is the function used to calculate the reputation in the competition, defined as follows:

$Y: P \times Rating \times Rank \rightarrow Rating$,

In which two inputs are included, input variable Rating representatives the past competition result, and the other variable Rank is the ranking of this round of competition.

Z is the reward function that the winner of this round of competition should obtain, defined as follows: $Z: P \times Rating \times Rank \rightarrow Reward$.

The reward obtained by a developer is decided by the developer and the task requestor based on the crowdsourcing software accomplishment quality as well as the reputation ranking of the developer. Usually, the programmer with relatively high raking can obtain more compensation. In this way, the community members participate in competitions actively, to promote their ranking and coding skills.

3.3 Governance organization

The governance mode of crowdsourcing software engineering is an assemblage of organizations, processes and policies, to guide and control the grouped development of the community, and maintain the common community value. With the support of open technology platform and transparent software frame, the governance organization can persistently coordinate the relationship between manpower, knowledge and resources of the community, to promote the development and progress of ultra-large-scale system in a prompt and adaptive way. The main body of governance organization is the community governance committee, the members of which are experts with

application field and software engineering background. The committee is in charge of sketching the overall shape and strategic decision of the project, to guide system development and achieve risk control. The governance committee should formulate and optimize correct policies and regulations on reward and reputation mechanisms, to enlarge the scale of community network, and maintain a team of developers with high quality. At the same time, the most powerful method of the governance committee is to set rules and development guides, to effectively standardize the development activity of the community. The governance committee must listen to suggestions and modifications of the stakeholder of the project, to formulate regulations which can be widely accepted by community members.

The governance committee needs to lead a working team, follow the policies of the governance committee and coordinate between various independent developers in the community. The working team members can be directly selected from the community members. Their responsibilities include:

1) Organize software requirement analysis: the working team should communicate with key stakeholder, to determine main function requirements and define preliminary requirement criterion. As for the ultra-large-scale system, the stakeholder must be very large scale community. The working team needs to adopt the grouped calculation mode of Wikipedia, collect requirement information by online human network, and generate complete analysis report[5][6]. Once a new requirement point is found by the software requirement analysis, the working team needs to update requirement analysis in time, and start a new round of competitive development, to achieve the new function requirement in a high priority.

2) Design software system structure and lead ecological platform development. After determining the requirement criterion, the working team can start to perform preliminary stage software system structure design, and define main function components and software structure style. After the structure planning, the primary task of the working team is to achieve the core general function of the system, to construct a solid and reliable open platform, to achieve the sustainable development of the whole software ecologic system. In some cases, the working team even needs to develop related software tool and environment in different levels, to support the corresponding community members to perform grouped development work. The working team can fully reference the past software project achievements or open source achievements, to improve the present platform and increase characteristic function.

3) Resolve the overall design and release crowdsourcing software development guide; the preliminary design detailed specification document can be released by the working team to the community, to mobilize community members to achieve the needed crowdsourcing software entity. The working team must at the same time create online coordination tool, to achieve collaborative design and discussion, to encourage the community to participate.

4) Review the intelligence of grouped developers; one of the main tasks of the working team is to find suitable developer in the community to achieve each crowdsourcing software entity. According to the detailed record and ranking provided by the reputation system, the working team can screen out the optimized member with development competence and field knowledge from the applying developers.

5) Review the crowdsourcing software product quality; it is very important for the success of grouped development project's success to review all the submitted crowdsourcing software, examine them whether in accordance with the criterion, and whether to achieve the quality requirement. The working team members are all programming experts, with the competence and experience of testing the crowdsourcing software's correctness and quality. At the same time, except for the expert review, the working team should encourage the end-user of the community to perform function test to crowdsourcing software entity and compile feedback opinions. With the evaluation of the crowdsourcing software from the comprehensive experts and general users, the working team can ultimately determine the best crowdsourcing software achievement, and provide the developer with reward.

The governance organization of the App Store of Apple Inc partly realizes the above described organization mode, especially on crowdsourcing software review aspect. It has a review committee consists of 40 people, perform analysis and test on each provided ISO application according to the review guide of App Store. But the review course of Apple Inc is neither open nor transparent; the review is totally performed inside of the company to guarantee the mobile phone application quality. This behavior causes some disputes, and the American FCC even performed survey and inquiry on it. Besides, the closed behavior brings abundant workload to the review committee, and greatly delays the passing time of crowdsourcing software.

Conclusion

The crowdsourcing software engineering method shows increasingly powerful advantage on the development problem of ultra-large-scale system; on this overall background, this article firstly discusses on the development mode of crowdsourcing software development basic element, and the coordinative competition mode is the main way of crowdsourcing software development. In order to better coordinate the competition relationship of crowdsourcing software development, this article discusses three governance problems of reward, ranking and top layer governance in software process governance, to better mobilize the enthusiasm of community members, improve the condition of the overall software ecological system, and promote software development efficiency and quality.

The implement of a Linux database data processing mechanism based on cache

Yongjun Zhang[1, a], Chunhui LI[1,b]

Photonics and Optical Communication and Optoelectronics, Beijing University of Post and Telecommunication, Beijing, China

yjzhang@bupt.edu.cn

lichunhui1014@163.com

Keywords: database; cache; IOT(Internet of Things); gateway; embedded Linux operating system

Abstract. Although the simple structure and easy operation of completing data process depending only on the real-time request of database, the database call time is far longer than the lookup time. If the database is called too frequently, the processing speed will surely be cut down and the real-time performance will be degraded. Based on the situation, this paper will put forward one method, which combined cache with database can improve the performance of the system in the main controller of integrated security system of equipment management.

Introduction

Database is an important tool to store, share, dispose data and even manage information now. Database performance optimization has become an important topic.SQlite which is contained in a C programming library is a relational database management system.In contrast to other database management systems, SQlite is not a separate process that is accessed from the client application but an integral part of it. The operation is faster than the current most popular database. Provide support for the transaction function and concurrent processing. The application of the transaction, not only ensure the integrity of the data, will also improve the running speed.

Cache is a memory chip in the hard disk controller which has extremely fast access speed. It is the buffer for the interior memory and the external interface, and is usually used in RAM to save temporary data, which can be missed once it is powered off.

Theoretically, base on the high access speed of cache, the method embedded database combined with cache can optimize the traditional great. This paper presents the integrated security system of equipment management, in which the embedded service gateway combines the traditional internet with the new type of sensor network. In this system the embedded service gateway plays the role of the coordinator gateway of wireless sensor network, and becomes the remote web client, which makes it possible to communicate between two different protocols. Because of the hardware characters of Reader in the bottom layer and the inflexibility of handling with data, we can only pass the status information to the embedded service gateway directly. It analyzes the data with information in the database to get the relevant signal. The signal will be saved in the record and post to web server.

The realization of the processing mechanism

This system adopted the wireless sensor, the embedded system and some other techniques. From the beginning of equipment distribution, it took the real-time monitor and protection for the needed equipment, which made the superiors be able to master the subordinate equipments status. When one moved with illegality or violation, it would get the alarm message. As a result we could avoid the equipment accident occurrence.

Fig. 1 shows, the integrated security system of equipment management was divided into three layers [1-2]: the perceptual layer, the transport layer, and the presentation layer. The perceptual layer received information from the active label RFID(Radio Frequency IDentification), which included

labelID, the current energy, position and other related information. The reader made all the data about labels in combinations and then encapsulated in certain rules, finally post to the main controller. The transport layer was the main controller which received and analyzes data, and then produced register, loss, return, lowpower, access door, on-off of the safe signal, finally reported to the web server. The presentation layer was the web server. It received signal from the main controller, and can also make remote alarm if needed.

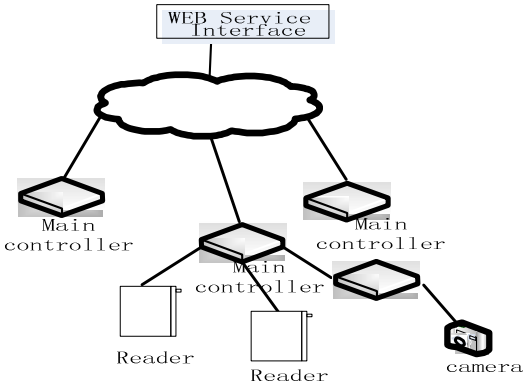

Fig. 1. The Structure of the Integrated Security System of Equipment Management

The main controller code of this system was achieved by Qt. It is a fully objected-oriented, easy to expand and allows a true component programming c++ application framework. And it encapsulates the access detail which adapts to the different operation system, which makes it be able to deploy with a variety of desktops and embedded systems quickly [3].

The main controller core was divided into two modules [4-6]: communication module and data processing module. The former was corresponding to the input and output of the central processor in figure2; the latter was corresponding to the handling part between central processor and database.

Communication module

Communication module was the basic module in completing the function of main controller. It included two sub-modules, multi-threaded server and the client of http. The former was used to communicate with multiple readers, get RFID information, listen and get connected with QTcpSocket and QTcpServer and so on. The latter, was used to report the effective information to web server.

Multi-threaded server. Fig. 2 shows the data processing flow:

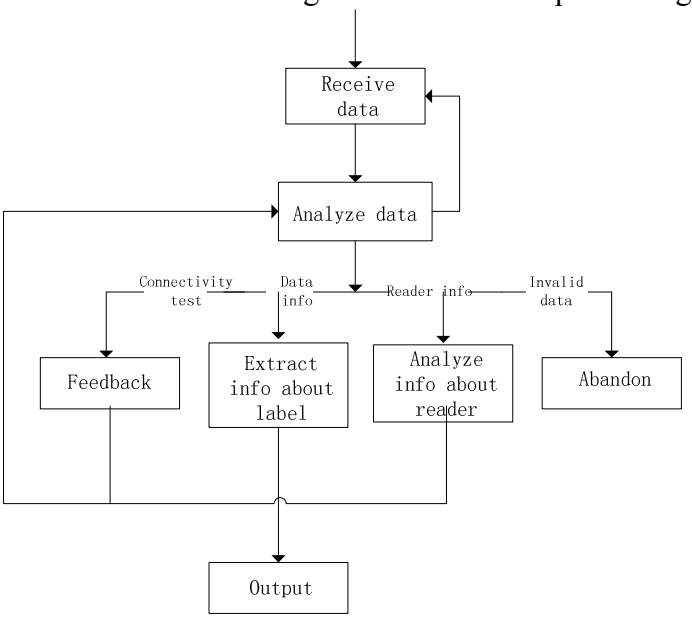

Fig. 2 Data Processing Flow

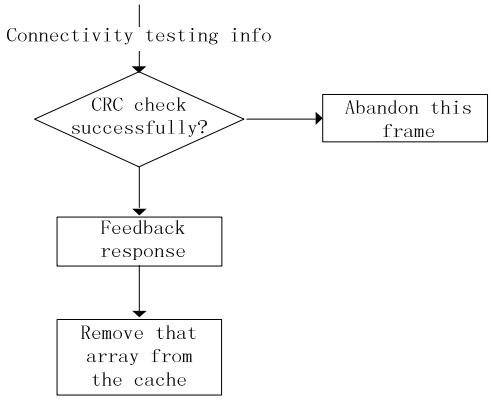

Fig. 3Connectivity Testing Part

Connecting part for testing is shown in Fig. 3.After connected with main controller, we could make sure whether the line is alive or not, through receiving and sending connectivity testing information. If the line was normal, we could switch the available message. Because of the smaller length of frame and the simpler structure than the normal data frame, on one hand it might reduce unnecessary traffic, on the other hand as it was easier to parse, it could reduce the handling stress.

As for the message about label in Fig. 4, we needed to get the Reader ID, and acquire the message about Reader. And then stored labelList, lopedList, and some other lists in the cache, passed them to the database. Finally took the corresponding disposition.

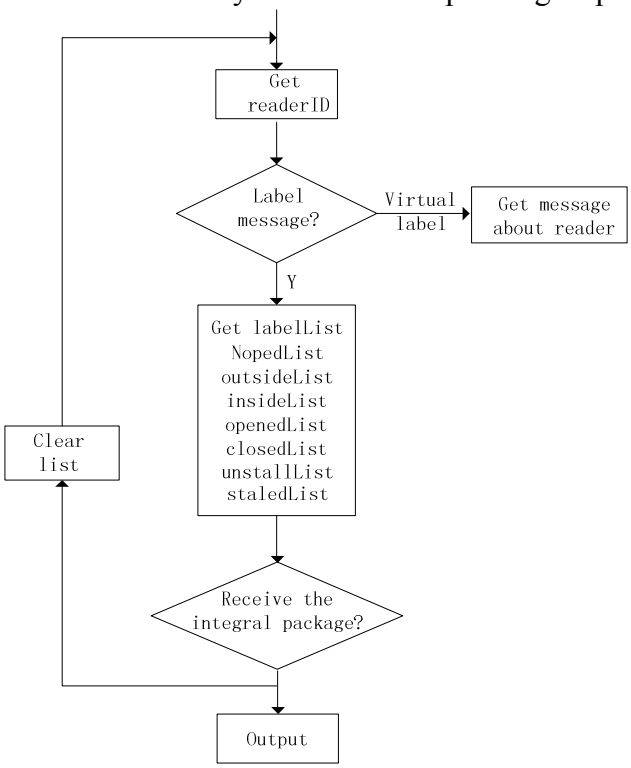

Fig. 4 Get Message about Label

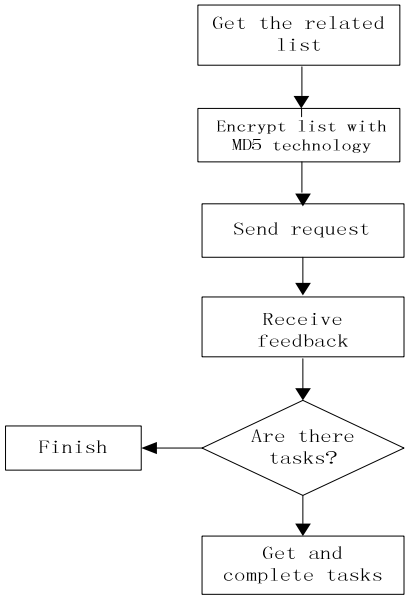

Fig. 5 Heartbeat Message Flow

HTTP Client. There are three interfaces to connect with WEB Server, register, status, and heartbeat message. To enhance the safety, we employed MD5 encryption technology.

Register message was the same as status message: got the related list->encrypted List with MD5 technology->sent request->received feedback. Fig. 5 shows the heartbeat message flow.

Data processing module

It was the core module to achieve the function of main controller. Data processing module summarized data from the transport module, and analyzed with database, then passed them on transport module.

We could get such signals as: register, loss, return, go out, enter the door, open the door, close the door, and temper signals.

Get register, loss, return signals. Fig. 6 shows report process. Implementation approach: First, we could get labelList through labelID in transport module, then after compared with data in the database, we got the related message.

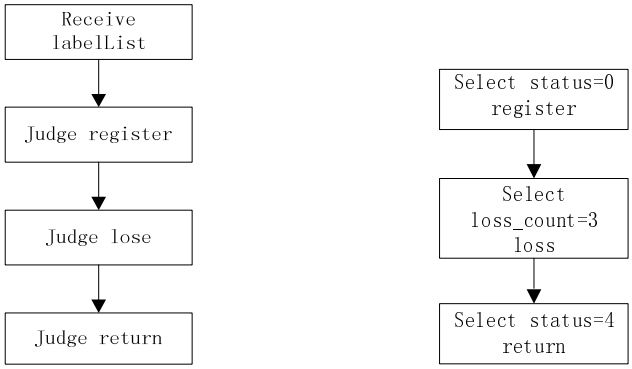

Fig. 6 Report Process

We got these three signals by comparing the LabelList with data in database, as is shown in Fig. 7 and Fig. 8.

(1) Register signal

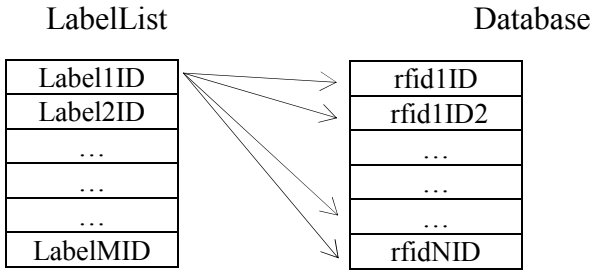

Fig. 7 Register Match

Find every item that from LabelList in database. If

Successfully: Leave alone.

Unsuccessfully: Insert that item into database. Set status = 0;

In this part we bring in status row, which is used to record rfid status, as Table 1 shows.

Table 1 The position status value

0	1	2	3	4
Register but not report	normal	Lose but not report	Lose and reported	Return

Report process

Start the timer, and report every three seconds. Find the items with status = 0, and then put them in the regiList, finally report them to the server, and set status = 1.

(2)Lose signal

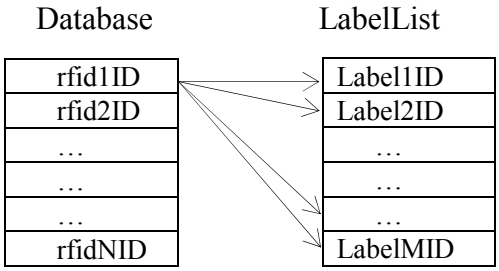

Fig. 8 Loss Match

Find every rfidID item from the database in the LabelList.

Successfully: Leave alone.

Unsuccessfully: Set status=2, and increase loss_count value by 1.

When the reader receives message from the label, it is impossible to receive all the label message at any time, because of the obstacles. To avoid the misinformation, we make the reader report lose signal, only if it does not receive that label in three consecutive times.

Report process

Start the timer, and report every three seconds. Find the items with loss_count = 3, and then put them in the lossList, finally report them to the server, and set status = 3, loss_count = 0.

(3)Return signal

To dissolve the misinformation:

Find the items with status = 2->Find that items in LabelList

Successfully: Set status = 1, label_count = 0 in database.

Unsuccessfully: Leave alone.

Return signal:

Find the items with status = 3->Find that items in LabelList

Successfully:Set status = 4, label_count = 0 in database.

Unsuccessfully: Leave alone.

Report process

Start the timer, and report every three seconds. Find the items with status = 4, and then put them in the retuList, finally report them to the server, and set status = 1, lo**ss**_count = 0.

Power, access door, opening and shutting door and tamper. Implementation thought: Firstly, we can get the position, power of the label and the state of the door the tamper state. That is, we can get these lists, such as, insidList, outsideList, lopList, nopList, openedList, closedList, instList, uninstList. Then, we find every list labelID in the database, if the status changes, we should make out the related signal.

The related keyword in database is as table 2 shown.

Table 2 The other status value

Lowpower(int)	Position(int)	Uninstall(int)	Door_state(int)
0-low power 1-normal power	0-out of the door 1-inside of the door	0-installed 1-uninstalled	0-shut down 1-open

Conclusion

When applying the mechanism which combines cache with database to main controller of integrated security system of equipment management, it can not only control the delay in 0.001 second or so, but can also run stably in the system.

Experimental Data Publishing Based on Browser/Server for Neutral Beam Injection in EAST

Rui Zhang[1, a], Chundong Hu[1, b], Peng Sheng[1, c], Xiaodan Zhang[1,d], Yuanzhe Zhao[1,e], Deyun Wu[1, f], Qinglong Cui[1, g] and Yulian Lin[1, h]

Keywords: NBI, B/S, data, experimental results, publishing, AJAX, JFreeChart.

Abstract. In the experiment of Neutral Beam Injection (NBI), Experimental Data Publishing Software (EDPS) is developed to get experimental data monitored remotely. Adopting B/S module, EDPS publishes information, such as experimental configurations and results on the Internet dynamically. The design and implementation of how EDPS uses the present information source in NBI Control System (NBICS), the procedure EDPS handles the requests from clients and displays the information on web pages are introduced in this paper.

Introduction

NBI system is employed on Experimental Advanced Superconducting Tokomak (EAST) for plasma heating and plasma current driving to support the steady-state operation and physical research [1]. NBICS is a subsystem which takes charge of monitoring the experimental operation process and interlock protection. Besides, it implements data collection processing and network communication [2]. During the experiment, NBICS collects experimental configuration, current value and voltage value of magnet power supply, gas valve, arc power supply, etc. This information makes great contribution to experimental result analysis.

EDPS acquires experimental data and publishes them on the Internet. With the implementation of EDPS, users who cannot get access to the Local Area Network (LAN) of NBI system can get an approach to experimental data acquisition.

Requirement and Analysis of EDPS

NBICS consists of four levels: remote control level, main control level, field control level and video monitoring level [3]. In each discharge, Main Control Console (MCC) in remote control level sends configuration to Main Control Server (MCS) which is located in main control level. Then MCS transits the command to subsystems and acquires the results collected in field control level. In this process, MCS saves all configurations and results. For the sake of analyzing the data, this information needs to be published beyond the LAN. Take security into consideration, MCS needs to be isolated from Internet in case that the data are modified illegally. So a platform connected with main control net and Internet is established. EDPS is software running on this platform, collecting experimental data and publishing them on the Internet. EDPS is implemented with the following specific functions:

a. During the experiment, EDPS displays the current configurations of the experiment, including shot number, voltage, and amplitude and pulse width of each sub-system.
b. EDPS displays experimental results collected by different channels in the form of waveform dynamically.
c. EDPS offers inquiry service for historical data, such as experimental configurations, spectrum results, etc.

Implementation

EDPS adopts B/S model. Clients can access data on the server by using a browser. This model decreases the burden of clients and developers. Besides, it provides an easier way to update software. The architecture of EDPS is shown in Fig. 1 (parts in dotted box). Data acquisition module takes charge of the communication with MCS to acquire experimental data. Request processing module processes requests from clients and transmits data between server and web page display module. Web page display module displays experimental data in appropriate forms on web pages.

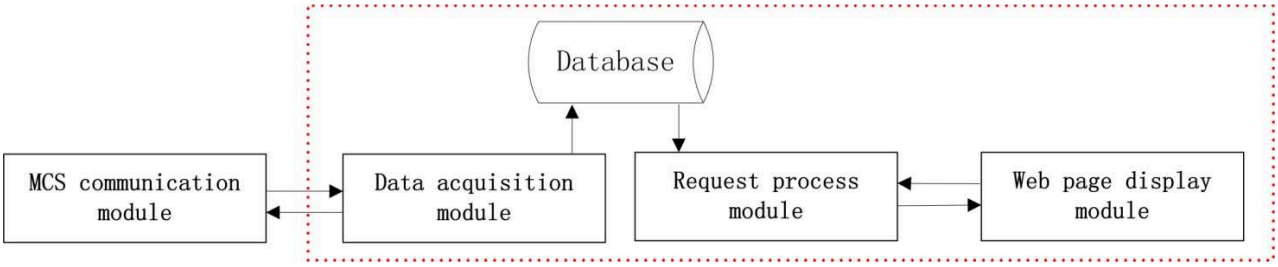

Fig. 1 Architecture of EDPS (parts in dotted box)

Design of Data Acquisition Module

In this module, programs are developed in C/C++ language, with a C/S program model based on standard TCP/IP protocol and multi-threading technology. The NBI TCP communication data structure is defined as it is shown in Fig. 2. The numbers at the top of figure express the size of bytes in different fields [4]. In every discharge, MCS sends information under this structure to EDPS, then EDPS analyzes the information and saves the data into MySQL database thus to provide an interface for request processing module.

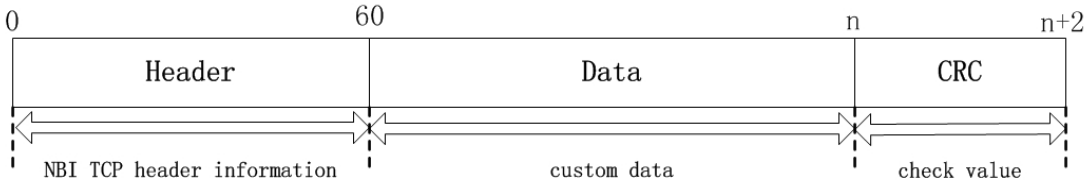

Fig. 2 Definition of the NBI TCP communication data structure

Design of Request Processing Module

In this module, Java Web techniques, especially servlet, Asynchronous JavaScript and XML (AJAX) are applied to process requests from clients. Taking advantages of specific class, servlet based on Java checks whether the requests is legal, then servlet invokes specific Java Bean to handle the requests and transmits responses to Web page display module or AJAX programs. Java Bean mainly handles the database by taking advantage of the application of connection pool. The work procedure of Java Bean is shown in Fig. 3.

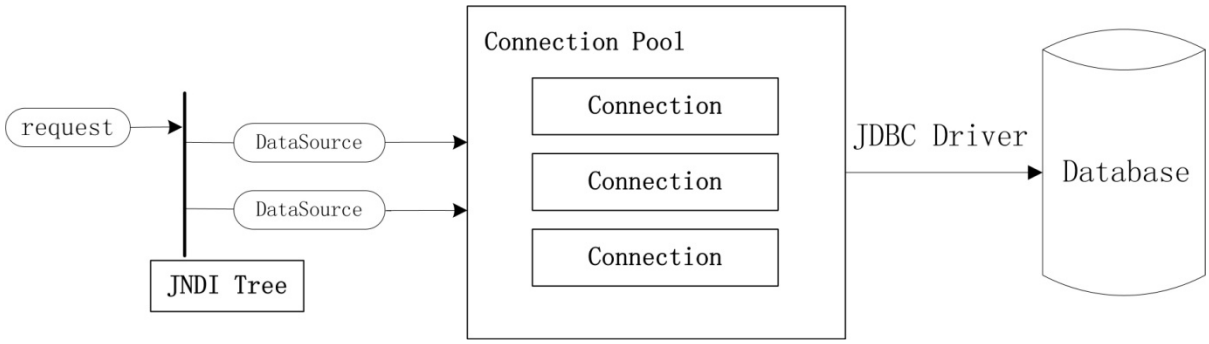

Fig. 3 Work procedure of Java Bean

AJAX is adopted to implement partial update of web pages in order to avoid the waste of bandwidth [5]. The programs are developed by JavaScript which are embedded into Hypertext Markup Language (HTML) or Java Server Page (JSP). Since experimental data change dynamically, AJAX programs send requests to servlet in every period to get the new information from database. In this way, web pages are refreshed dynamically to show the changes. The application of AJAX frameworks optimizes this module.

Design of Web Page Display Module

Experimental data are published in the form of table and waveform. This module is developed mainly relying on JSP and HTML. Some configurations are shown in the form of tables which can be directly printed on web pages, while other data, such as the amplitude and pulse wide of power supply, results collected from different channels are better to be displayed in the form of waveform.

Waveform is generated by JFreeChart, which is a library developed by Java. This library supports for many output types, including Swing components, image files (including PNG and JPEG), and vector graphics file formats (including PDF, EPS and SVG) [6]. In this module, waveform is imported by image files. Apply data by using the Class 'chartUtilities' and use the method 'writeChartAsJEPG' to output image in format of JPEG. Using the method 'writeRenderingInfo' can generate MAP data. MAP data enables clients to read the accurate value of each point of the waveform by keeping the mouse pointer staying. The work flow of generating waveform by JFreeChart is shown in Fig. 4.

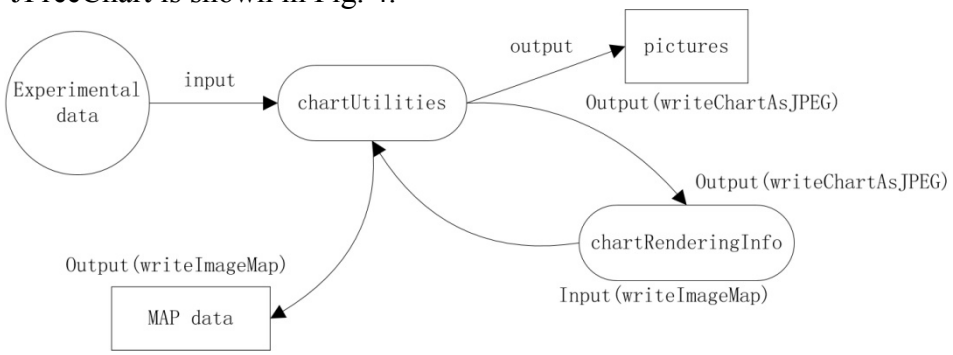

Fig.4 Work flow of generating a waveform by JFreeChart

Conclusion

The design and implementation of each sub module of EDPS are described in this paper. EDPS meets the requirements of publishing configuration and experimental results dynamically and providing service for inquiry. By adopting B/S, EDPS provides a method to analyze experimental data for those people on the Internet network.

Three Networks Convergence Analysis Based on SWOT Theory

Zhang Rui[1], An Ying[2]

Harbin University of Science and Technology, School of Management, Heilongjiang Harbin, 150040, China

zhangrui0619@163.com

Keywords: three networks convergence; SWOT theory; information industries

Abstract. With the development of information technology, the three networks convergence are making progress on technology, policy and market fields in China. This research analyzed the CATV, telecommunication and internet industries based on SWOT theory. It found they have different strengths, weakness, opportunity, threats in different industries. So we found the problems on three networks convergence and proposed the suggestions.

Introduction

Three networks convergence has developed for over ten years. It refers to the convergence of CATV, telecommunication and internet on the physical layer. With the development of the industrial chain of vertical and horizontal in China, the network system, terminal, business, institution and policy and so on, which have shown the trend of convergence. The subjects of three networks convergence make technology convergence through the interconnection, use the same IP protocol, and strengthen their infrastructures' construction. The subjects of three networks convergence take the method of mutual penetration and mutual cooperation in the business aspects, take the mode of coexistence of competition and cooperation to promote the development of the three networks convergence, thus provide superior service for people with low cost, diversification and humanization, personalization, multimedia service and so on.

According to the present situation of three networks convergence in China, the technology has been no longer the main factors influencing the three networks convergence. In terms of CATV, telecommunication and internet who have their own customer groups, and occupy a certain market share, CATV and telecommunication with monopoly management system lasted for decades, so the two major subjects are conservative. They also think that they have vast domestic market and customers. When three networks convergence begin, they are worried that their own interests will be affected. On technical and business aspects, each operator of them will keep some secrets, therefore, which is not conducive to the development of three networks convergence.

SWOT analysis is first proposed by K.J. Andrews who is a professor in Harvard Business School. SWOT was mentioned in his book "company strategic concept" in 1971 [1]. SWOT analysis tool is a kind method of enterprise strategy analysis S represents strength and advantage, W represents weakness, O represents opportunity, T represents threat. The S and W are the internal factors. O and T are external factors.

According to the SWOT model, this research mainly analyzes the present situation of three networks convergence as well as the present problems in China, and give some policy suggestions to promote three networks convergence.

Analysis of the telecommunication industry based on SWOT model

Before 2008, the telecommunication industry was composed of China Telecom, China Railway Telecom, China Network Communication, China Unicom and China Mobile. Due to the competition mechanism becomes more and more invalid in the telecommunication industry. The services of fixed telephones gradually declined, more and more users turned to mobile services; so it needs to create a better network to communicate, to resolve consumers' complaints, to carry out the "full-service" for telecommunication. Therefore, the companies were restructured, and they are known as the China Telecom, China Unicom and China Mobile.

On the background of three networks convergence, the method of SWOT analysis was carried out on the telecommunication. The advantages of telecommunication networks (S) as followed. Telecommunication has wide coverage, advanced technologies, perfect equipment, high qualities, abundant talent employees, well-managed, gradually improvement of service qualities, plentiful and valuable experience in market, diverse business model, and a certain of monopoly. Telecommunication's weaknesses (W) are that telecommunication has still provided telephone calls which has become saturated, and telecommunication is lack of the operating experience in content. Enterprise's strategic management and innovation are inconsistent with trend of development. To draw lessons from advanced system, telecommunication companies need innovate on telecommunication business and explore a profitable business model [2].Telecommunication's opportunities (O) are huge market, improved laws and regulations, and strategic made by Chinese government. With the sustained and rapid development of national economy, a huge demand of potential market is formed, and provides a greater opportunities for the development of Chinese telecommunication companies. The laws and regulations of telecommunication industry have constantly improved, telecommunication industry will enter a new stage. Chinese government promotes strategic decision-making of the national economy and social information, and creates the opportunity for the development of telecommunication companies. Telecommunication's threats (T) are employees and regulations. The competitive structure of telecommunication competition has switched from locally to comprehensively, from simple to diversity; the talent drain in industries is very serious. The influences of asymmetric regulation are also very serious. They are influenced by on business license, connectivity, telecommunication charges, universal service and so on [3].

Analysis of the CATV industry based on SWOT model

SWOT analysis was carried out on CATV. The advantages of CATV(S) include that penetration rate of CATV users is very high, and CATV has the advantage of the monopoly operation. It also has the advantage of the cable TV network, rich spectrum resources, and the advantage on technology research and development. CATV has advanced hardware and many financing methods. CATV also has a strict management system. The weaknesses of CATV (W) as followed. CATV has been in a state of self-sufficiency, and its profit model is single which needs to be innovated. Cable TV broadband network is seriously impacted by "multi-business bundling" of the telecommunications, leading to the growth of business slow. At the same time, the system of customer service is not perfect. The majority of users are the single mode, and the convergence with telecommunication business and Internet business is slow. The social welfare is strong, CATV is hard to achieve full market-oriented operation. The main opportunity of CATV (O) is policy. Under the environment of three networks convergence, CATV has more opportunities than challenges with the policy support. CATV should cooperate with telecommunication to develop the value-added businesses of bidirectional interaction, high-definition television, video on demand, broadband services, and to promote the transformation to the multimedia service provider and establish a new

development mode. The threat of CATV (T) is only one network. CATV does not form a "national network". Monopolization makes CATV be short of market competitive abilities and completely regulated by the state policy. Other enterprises have the advantages of full-service management. The user's mind about the service of CATV is free or low-cost. Market competition is becoming more and more intense [4].

Analysis of the Internet industry based on SWOT model

SWOT analysis was carried out on the Internet. The advantages of the internet (S) are that the scale of Chinese internet users is enormous. The rate of internet penetration is very high, most of people have computers, and almost all of adults have mobile phones, as a result, the penetration rate of user is very high. The physical infrastructure system of Internet is comprised of individual terminals, family terminal and industry terminal. IP address and domain name are the core resources of Internet. We can use IP address and domain name to perform dynamic addressing, and it can provide many business application, such as public cloud, private cloud, support cloud etc.. The main weakness of the internet (W) is broadband. The broadband of the internet is not enough, the speed of the internet is not enough; the credibility of the Internet is relatively low. A lot of bad events usually happen on the internet, such as Trojan virus, account stolen, information disclosure, consumer fraud etc.. The government is in favor of CATV and telecommunication, therefore, the government will give some additional support on policy to CATV and telecommunication, but the internet does not have such preferential support. The opportunities (O) of the Internet are about company. The Internet company arose that can provide the service of the world. To a certain extent, a number of shops and enterprises gain new business opportunities, and they can transfer the business pattern from offline to online. Meanwhile, they provide more job opportunities for people, such as the generations of logistics company, the third-party payment etc.. The position of the Internet is to become the information infrastructure of the society. Technological breakthrough of "terminal and cloud applications" promotes the explosive growth of mobile internet, Internet application is facing new innovations and more opportunities. The fusion of mobile, social networking, and big data etc. will produce some new business models, those industries are very promising in China [6]. The threats of the Internet (T) will gradually change the model of competition. Internet needs higher technologies and more secure platform than before. Many internet companies cannot reach the standards, so many companies will go to abroad which results the scale of market is smaller in China. It's an enormous challenge to improve this situation for us. Determine how to improve the reliability of network is also a huge challenge.

Policy proposal

In terms of policy, we give some suggestions

Firstly, establish a united regulatory system which is benefit to the real realization of three networks convergence. Only when the government builds a united regulation for the businesses of CATV, telecommunications and the internet, it can make progress of technology and the development of the market.

Secondly, propel and establish full-service operators for three networks. The scale of Cable TV network operators is different which needs to be integrated. The government should take some measures to separate government from the enterprises, separate program from broadcasting, and separate network from platform. It impels and sets up full-service operators, and builds a fair and healthy environment for market competition and cooperation by the reform and recombination of the telecommunications.

At last, develop and introduce a relatively perfect legal protection system. In order to promote the sustainable development of three networks convergence, the government and related departments should speed up to develop related legislation, and provide the perfect legal protection system.

In terms of technology, we give some advices

The first one is to integrate the networks. The network of traditional communication in China means that the government and related departments put the network into hierarchical construction, management, deployment and operation. Because of the communication network scattered, there are some contradictions of the transmission in terms of the business of voice, video, data etc.. Therefore, the system should be reformed, and the technology should be transformed in the large-scale to achieve the effective integration for the network, realize the connectivity of technology, business, market, policy etc..

The second one is to increase the validity bandwidth of broadband network. The bandwidth of access network has become an important condition which restricts the entrance of telecommunication industry network and the internet into the business of CATV. The operators of telecommunication industry should modify current data network to increase the validity bandwidth of broadband network.

In terms of market, we give some recommendations

Develop the competition environment of market. Relevant departments and government should build a fair and just market competition mechanism, regulate the competition of CATV and telecommunication, and cultivate a good market environment. The development of the three networks convergence, CATV and telecommunication should put aside of their own interests. It is important for all of them that share the technology and business, collaborate actively, and achieve the further development of three networks convergence.

Increase the investment, improve the quality of the business, and expand the scope of the business. They must take some measures to attract more customers and sponsors if the enterprise wants to increase the share of market. The business should change from simplification to diversification so that improve the enterprises' competition ability.

Keywords: Power Distribution and Utilization Business; Analytic Hierarchy Process; Weights; Quality of Service

Abstract: To further improve the quality of service of communication business for power distribution and utilization, and to meet the needs of communication network for smart power distribution and utilization, we propose a multi-network switching model based on AHP; First, this model analyzes the performance of LTE, WCDMA and WiFi, to determine the integrated weights of optional network by solving the relative weight of rules and index, then select a network which is based on guarantee the performance index of QoS; In the process of transmission of power distribution and utilization business, take the transmission efficiency as the optimization target, the network of which weight is larger is priority to transfer power distribution and utilization business; Simulation results show that the model can improve the quality of service of communication business for power distribution and utilization.

Introduction

For power communication systems, no one single communication system can fully meet the communication requirements. Under the current power system, data acquisition, remote transmission, video surveillance and load management, of which is the multi-mode multi-service environment, then it is necessary to take an integrated communications system while according to the specific conditions and make mutual integration between the various networks, which can meet the requirements of the power communications system [1, 2].

For many types and complex communication business for power distribution and utilization [3, 4], this paper proposes a multi-network switching model algorithm based on AHP in order to avoid the data backlogs, transmission delays and others. The algorithm is aimed at improving the network efficiency, and using AHP to analyze the QoS performance of these three wireless networks. This paper studies bandwidth, economy, transmission distance of an optional network, and then determine the weights of the three networks under different criteria; Since the transmission business requires different bandwidth, economy and transmission distance, and determine the integrated weights of the three networks. The larger weight is priority to transfer power distribution and utilization business, which can effectively improve the quality of services of communication business for power distribution and utilization.

Network Environment

To improve the quality of service of communication business for power distribution and utilization, this paper puts forward a multi-network switching model, while is transporting the business data, the multi-mode terminal can real-time detect whether the current network environment in which a variety of wireless network coverage, and search the various network performance parameters, determine the comprehensive weights of each network, it priority to switch to the larger weight of the wireless network. As shown in figure 1, this paper studies the environment located in three overlapping coverage area of the network, namely, LTE, WCDMA and WiFi.

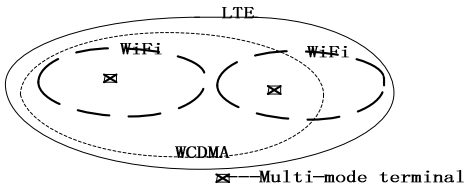

Fig. 1 The study environment

In order to further determine the relative importance of each network performance, this article adopts the analytic hierarchy process (AHP) to analyze the performance index of LTE, WCDMA and WiFi.

Construct the hierarchical structure model

Using the analytic hierarchy process (AHP) to deal with multi-attribute decision making problems, first of all, clear objectives, construct the hierarchical structure model, then determine the subordinate relations between adjacent level elements. Target layer as the highest level indicates that problems needed to be solved, the problem needed to be solved in this paper is to determine comprehensive weight of three networks; Rule layer usually indicates influencing factors of bidding decision, we choose a transmission bandwidth, efficiency and the transmission distance as the three factors in this paper; Index layer indicates specific indicators or parameters of the project evaluation, namely, various specific indicators under the rule layer, such as the three kinds of wireless networks in this paper [5,6]. In a variety of wireless network environments, this paper constructs the hierarchical structure is shown in figure 2.

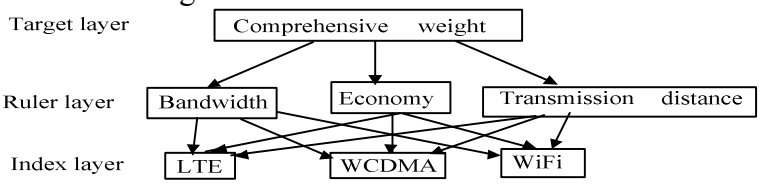

Fig. 2 The hierarchical structure model

As the comprehensive weight of target layer is determined, multi-mode terminal can choose the network of high weight to switch, and make the best network access.

Construct judgment matrix

Set ruler layer has n elements, $x_1, x_2, \cdots, x_n$ which affect the choice of the target layer. First compare the relative weight between n elements, then select two elements x_i, x_j and comparison, a_{ij} indicates the importance ratio between the two elements, and finally, after all the factors pairwise comparison, $A=(a_{ij})_{n\times n}$ indicates the comparison results, called the judgment matrix.

According to Satty table 1~9 scale and its inverse to determine the elements of judgement matrix, Satty table is shown in table 1.

Tab.1 The Satty list law

Importance (compare A with B)	explanation
1	the same
3	a little
5	obviously
7	highly
9	extremely
2,4,6,8	the middle

Consistency check

Calculated the largest eigenvalue $\lambda_{\max}$ and the corresponding characteristic eigenvector W of the judgement matrix, then characteristic eigenvector is normalized processing, the consistency ratio CR is calculated by the type (1) and type (2).

$$CI = \frac{\lambda_{\max}(A) - n}{n-1}. \tag{1}$$

$$CR = \frac{CI}{RI}. \tag{2}$$

Among them, RI is the average random consistency index of same order matrix and RI is generally known, when $CR < 0.1$, determine the consistency of judgment matrix is satisfied, otherwise reconstruct the judgment matrix.

The relative weight between the various rules

Suppose the power distribution and utilization business demand for broadband and transmission distance requirements are the same, and bandwidth demand and the requirements of the transmission distance slightly higher than the economy. Bandwidth demand, economy and transmission distance affect the weight of the power distribution and utilization business, in different levels, so according to the Satty list method, the judgment matrix is:

$$A=\begin{pmatrix} 1 & 3 & 1 \\ 1/3 & 1 & 1/3 \\ 1 & 3 & 1 \end{pmatrix}$$

Calculated the maximum eigenvalue of the judgment matrix is λ_{max}=3, then the characteristic vector is normalized processing, get the weight vector $q=[0.43 \ \ 0.14 \ \ 0.43]$.

The relative weight of between optional networks under the rule of a single

Assumes that the user is currently having three kinds of network can choose, have two kinds of wide area coverage of LTE and WCDMA, and there is a smaller coverage of wireless local area network (WLAN) WiFi, we use C1, C2 ,C3 stand for these there network respectively. When multi-mode terminals detected these three optional networks, began to implement the analytic hierarchy process to determine the weights of optional network, then switching access. Judge the QoS performance parameters, mainly need to consider bandwidth, economy and transmission distance, we use X1, X2, X3 stand for these performance parameters respectively.

Bandwidth of wireless network can be measured by the transmission rate. According to statistics, these three networks transmission rate of LTE, WCDMA and WiFi is shown in table 2.

Tab.2 Transmission rate

category		LTE	WCDMA	WiFi
rate	uplink	50Mbps	5.76Mbps	11~54Mbps
	downlink	100Mbps	14.4Mbps	

Economy of wireless network can be measured by the reciprocal of the investment cost. According to statistics, cost of WiFi is low, WCDMA is higher, and LTE is higher than the 3G.

According to statistical analysis, although the current WiFi technology transfer rate quickly, but can only achieve short-range wireless transmission; Although LTE tariff is high, but the transfer rate is high, and can achieve the function of long-distance wireless transmission; Compared with LTE, 3G coverage more widely, the transmission distance is farther. When the business is transmitted to a certain distance, signal strength of 3G is better than that of LTE, and signal strength of LTE is superior to the WiFi.

This paper mainly studies how to select the optimal wireless network, and then to transmit power distribution and utilization business, so consider the uplink rate f selected network mainly. In conclusion, three kinds of network parameters is shown in table 3.

Tab.3 Network parameters

Parameter / network	X_1	X_2	X_3
C_1(LTE)	50Mbps	low	long
C_2(WCDMA)	5.76Mbps	high	longest
C_3(WiFi)	54Mbps	highest	close

With Satty table 1~9 scaling method for the analysis of table 3, pairwise comparison of optional network of LTE, WCDMA and WiFi, the judgment matrix of bandwidth is A_1; the judgment matrix of economy is A_2; the judgment matrix of transmission distance is A_3.

$$A_1=\begin{pmatrix} 1 & \frac{50}{5.76} & \frac{50}{54} \\ \frac{5.76}{50} & 1 & \frac{5.76}{54} \\ \frac{54}{50} & \frac{54}{5.76} & 1 \end{pmatrix} \qquad A_2=\begin{pmatrix} 1 & 1/5 & 1/7 \\ 5 & 1 & 1/3 \\ 7 & 3 & 1 \end{pmatrix} \qquad A_3=\begin{pmatrix} 1 & 1/5 & 5 \\ 5 & 1 & 9 \\ 1/5 & 1/9 & 1 \end{pmatrix}$$

Calculated the maximum eigenvalue of A_1, A_2, A_3 respectively, we acquire λ_1=2.6248, λ_2=3.06, λ_3=3.12. Then the corresponding characteristic vector is normalized processing, get the weight vector $q_1=[0.559 \quad 0.064 \quad 0.377], q_2=[0.072 \quad 0.279 \quad 0.649], q_3=[0.207 \quad 0.735 \quad 0.058]$.

Comprehensive weights of optional network

In the process of transmission of power distribution and utilization business, the relative weight of optional network can be calculated using the weighted average method. Sort of optional networks by using the weight averaged method, the greater the value, the higher the priority. The relative weight between optional networks can be expressed as:

$$\begin{aligned} N_\omega &= [q_1^T \quad q_2^T \quad q_3^T] \bullet q^T \\ &= \begin{pmatrix} 0.559 & 0.072 & 0.207 \\ 0.064 & 0.279 & 0.735 \\ 0.377 & 0.649 & 0.058 \end{pmatrix} \bullet \begin{pmatrix} 0.43 \\ 0.14 \\ 0.43 \end{pmatrix} \\ &= [0.3395 \quad 0.3826 \quad 0.2779]^T \end{aligned}$$

The simulation and results

In this article, the weight of judgment matrix is calculated by using MATLAB software. In the process of running the program, always does not appear “The matrix does not pass the consistency check”, which explain that the judgment matrix all pass the consistency check, so the order weight calculated by the program is acceptable.

For different business, the degree of requirements of the transmission bandwidth, economy and the transmission distance is not the same. And this degree can be represented by the size of the weight, and the sum of the three weights is one. Therefore, simply select two variables in the process of simulation. First of all, in this paper, transmission bandwidth, economy and transmission distance of three kinds of optional network can be determined. Then to simulate the comprehensive weights of three kinds of network by MATLAB software, as shown in figure 3, figure 4 and figure 5 respectively. The X-axis represents the bandwidth, the Y-axis represents economy and the Z-axis represents the comprehensive weight of network.

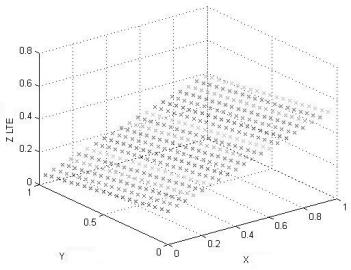

Fig.3 The weight of LTE

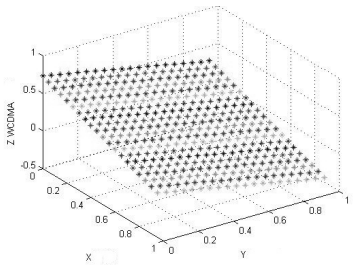

Fig.4 The weight of WCDMA

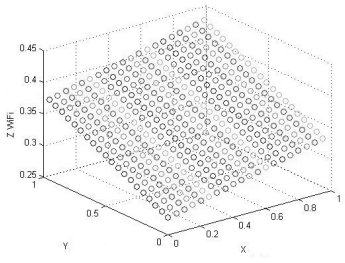

Fig.5 The weight of WiFi

Figure 3 shows that the weight of LTE increases along with the requirement of transmission bandwidth increases, increases along with the decrease of the economy. Figure 4 shows the weight of WCDMA increases along with the decrease of the transmission bandwidth and increases along with the decrease of the economy; Figure 5 shows the weight of WiFi increases along with the requirement of transmission bandwidth increases, increases along with increase of the economy. When choosing a network, only need to make sure that the user requirement for transmission bandwidth, economy and transmission distance, can be concluded from the simulation diagram of three optional network weights, finally choose the optimal network.

Conclusion

The simulation results show that make sure the level of requirements of the network performance, this algorithm can determine weights, can this algorithm can determine weights, can choose the best access networks according to the different needs of users, so as to achieve maximum transmission efficiency.

Keywords: Online Thematic Map; RIA; Active; Knowledge

Abstract. This paper analyzes two important problems of thematic map cartography facing, namely which technique solution is appropriate and how to simplify the cartography process. Firstly, contrasts some popular technique solutions of thematic map, and points out the bottlenecks and inconveniences of thematic map cartography process nowadays, then brings out active online thematic map cartography based on the technique solution of RIA (Rich Internet Applications). In addition, this paper gives out RIA-based implementation framework of active online thematic maps mapping, which is contrasted with RIA-based implementation framework of general online thematic maps mapping, and main methods of building knowledge of active cartography of thematic map.

Introduction

Thematic maps have been an ordinary application in various industries with its intuitive, efficient and novelty. From the application demand, online thematic cartography can meet the needs of user's real-time mapping and personalized mapping. With the popularization of network and network application requirements of thematic mapping, online thematic cartography becomes an important direction of geographic information science development, thus every one on the web can cartography thematic maps themselves anywhere or any time.

Firstly, from the perspective of software development, with B\S structure of the software model used widely, the original stand-alone thematic cartography has been converted as service-oriented and network based, which is the initial model of online thematic maps. At present, four technique solutions have been formed, that is, images of thin client, vector of thin client, vector of fat client and vector of rich client-side (RIA).

Nowadays, the modes of images of thin client and vector of fat client have been used in the LAN, WAN applications in many areas. But the mode of vector of thin client has many limitations for no unified standard of multiple browsers (IE, FireFox, etc.), which prevents it developing quickly, though it has good prospects for development because of its OGC Standards. Last technique solution in Table 1, namely vector of RIA, which is based on the mature lightweight plug-in technology to satisfy the demands of network and stand-alone application, such as flash technology, can address the needs of increasingly demanding from the beautiful graphics, high efficiency and good experiences of online thematic mapping.

The basic work of online mapping of thematic maps, namely the process of thematic cartography is not avoided, and the intelligence and complexity of this process have a direct impact on the effects of online mapping applications. At present, many software have done a lot of work in this area, such as sophisticated template technology mapping, which builds some steps to allow the user to select various parameters, then get the thematic maps, even though, which still having a big gap from easy mapping of thematic maps for persons without professional knowledge. So the author brings out the idea of active online thematic map cartography with reliable knowledge of thematic cartography, which can do lots of work for user as many as possible to reduce the complexity of thematic cartography, especially selecting confused, professional mapping parameters, such as thematic symbols, colors, grade num, etc.

This paper will talk about the realization method of RIA in active online thematic cartography and how to build the system's main knowledge to improve the practicality of online thematic cartography.

Framework of Active Online Thematic Cartography Based on RIA

On the basis of the application framework as Figure.1, we try to add the data search services, including search map data services and thematic data search service. When users needs only a thematic map drawing without their own mapping data and thematic data, the data search service will be available and using, which can search suitable data for users. In addition, thematic mapping symbol type, grade classification of data, data classification and the number of color choices can be fixed or judged based on user demand by active system to provide proactive service. In short, the initiative of active thematic cartography can be reflected in the two aspects as follows:

1) Searching data: active thematic cartography can search required data to the user initiatively, including the map data and thematic data, thematic data resources and various types of commonly used statistics, such as agriculture statistical data, industry statistical data.

2) Finding optimal parameters: active thematic Cartography can construct suitable parameters, and different requirements may construct different mapping parameters, including the mapping symbol type, data classification or grading methods, and the color or hue.

Obviously, to achieve the two purposes above, thematic map cartography knowledge and knowledge learning are necessary. Later in the article will introduce the process of main knowledge building.

The user interface can be designed as GOOGLE search engines (this is suitable to users without their own data especially)， which has input box only, and when users input some key words, then the cartography system gives the proper mapping results for users according to existing knowledge. Active Framework for online thematic cartography can be described as Fig.1.

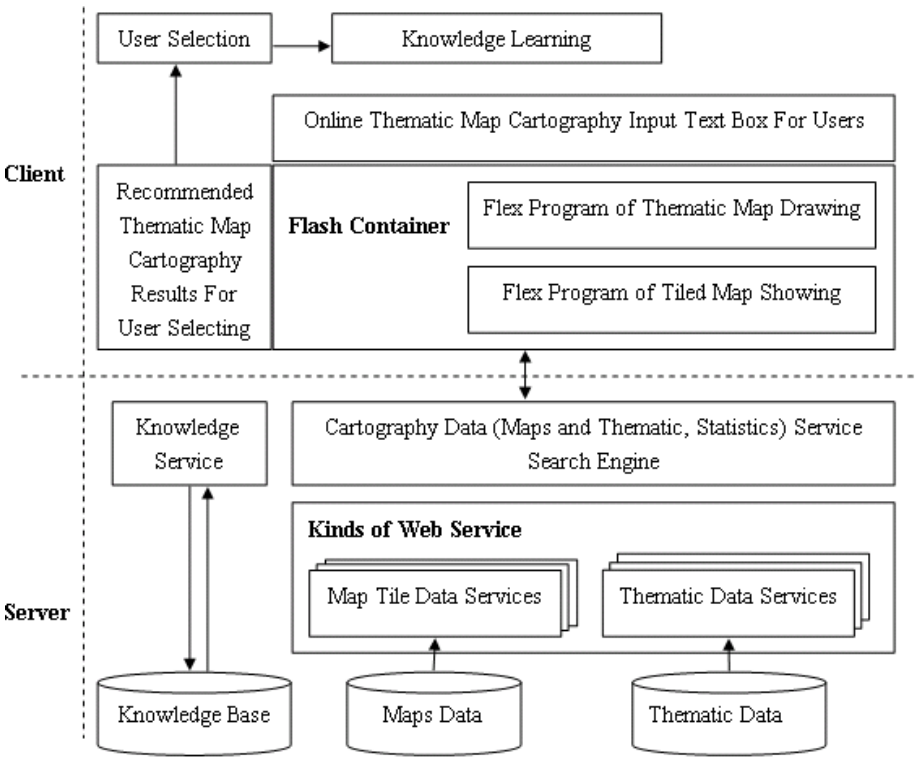

Fig.1 Technical framework for active online thematic cartography

The Main Knowledge Building for Active Thematic Cartography

In general, thematic map cartography can be divided into four processes: understanding，solution，evaluation and learning. Thus, analysis of thematic map data features is the first step in mapping, and the follow processes of knowledge building are closely linked with the data properties. The following describes the knowledge construction process with symbol types and colors to choose as examples.

The original adaptive knowledge building between thematic mapping Symbol type and data. First of all, thematic data is divided into one-dimensional, two-dimensional and multidimensional, with different dimensions of the data set can be divided into categories (qualitative schemes), sequencing (with order), fixed pitch (which can add and subtract), fixed ratio (which can multiply and divide) and irregular quantitative data, while the irregular quantitative data also can be approximated by different linear function or multiple functions by fitting or interpolation. In the five data types, the first two categories are qualitative data, the latter three are quantitative data. The quantitative data also shows the distribution of a variety of complex features.

Then, through study of thematic mapping symbol type, thematic mapping symbol type (histogram, pie chart, line chart, pyramid, etc.) can also be classified according to the dimension and data characters, namely, one-dimensional symbols, two-dimensional symbol and multi-dimensional. Further more, according to adaptability to classes, thematic map symbol types can get correspondence relationship with data classes. Given qualitative schemes, sequencing schemes, fixed pitch, fixed ratio and irregular quantitative coded with the A, B, C, D, E to indicate, adapting relationship table is achieved showing in Table 2.

Table 1 Adapting relationship between data and thematic mapping symbol type

Data / Sysmbol	One Dimension (A)					Two Dimension (B)					Multi Dimension (C)				
	A	B	C	D	E	A	B	C	D	E	A	B	C	D	E
Bar Chart(1)	✓		✓		✓	✓		✓		✓	✓		✓		✓
Pie Chart(2)						✓	✓	✓			✓	✓	✓		
…															
Pyramid Chart (N)						✓	✓	✓	✓	✓					
Color/Texture Map (N+1)	✓	✓	✓	✓	✓										

According to adapting relationships table above, when getting a group of data, by computing data statistical characters, some suitable thematic map cartography types are shown for users. To simplify the explanation, condition-action or condition-result mode can be used to describe the knowledge, such as Table 3, which gives some cases as examples.

Table 2 Some relationship knowledge cases with condition and action mode

Knowledge Type	Condition	Action
Initial	AC	1,n+1
Initial	BA	1,2,N
Initial	CE	1

The table above gives out knowledge type, knowledge condition and action (or result), which contains application examples from Table 1. In this way, the right type of thematic mapping symbol type is obtained to meet the expressed needs of the display of thematic data, which is helped by original knowledge, knowledge tested and Knowledge learning. On the original knowledge to pass the test of practice, validation, updates, and accumulation, that is, knowledge learning, are not discussed in this article in detail, and irregular quantitative data is also not discussed for further detail.

The original adaptive knowledge building between colors and data character and properties. Color is an important aspect of thematic cartography, how to select the color needs relevant knowledge. Different from thematic mapping symbol types, colors dimension is only the length of color group, even though, the dimension of colors is also the important element to color group's design, and color groups of different dimension have different color selection policy. In

addition, to highlight the special nature of industry-need, special data type parameters are needed, which describes data's thoughts features, e.g., fire as the emergency should be emphasized on red, but agricultural production and other green plants can use green. Similar ideas can be used as described in the original knowledge of color selection, which delegates experiences. According to the analysis results above, the following can be constructed to adapt to relationships between the data and the thematic color, as shown in the Table 3.

Table 3 Relationship between data type and color group

Data / Type	Qualitative	Categorical	Sequence	Diverging
Fire	S8,S10,S12	S4,S9,S11	S3,S12,S22	S21,S32,S52
Water	S9,S11,S16	S1,S2,S21	S6,S8,S15	S4,S5,S17
Plant	G3,G7,G8	G12,G19,G23	G23,G36,G68	G1,G2,G5
....	....	....	....	....

According to the relationship in the table above, some original knowledge of color choice can be formed. Table above lists the different color categories and data nature (type), which can find different group of color template code. In fact, user demand is sophisticated and different knowledge will be obtained from different angles, e.g., from the perspective of the display device, including CRT-Friendly, LCD-Friendly, Print-Friendly, etc., color schemes are also different. This needs further study.

In addition to the above, of course, there are other aspects of thematic cartography also need similar studies, and the formation of the corresponding knowledge helps to build a more reasonable active thematic cartography.

Summary

With the development of online thematic maps, and increasingly high demand of thematic map cartography, this paper discusses two important aspects of thematic maps cartography, namely technology routes and active cartography process, brings out RIA technology has practical significance for online thematic cartography, and probes the methods of knowledge building of Active online thematic cartography. By means of efficient RIA technology platform, active online thematic cartography can easily realize the beauty and animation of thematic cartography, including efficient user interaction. Active Online thematic cartography is a upgrade project of cartography of template, which can help cartographer without professional knowledge to quickly build thematic maps of professional level, promoting the wide use of online thematic maps applications.

Further study will be still needed about knowledge, learning system, detailed technique solution route and also application model, which is the important base of active online thematic map cartography with high efficient, convenient, and easiness.

Keywords: painting pattern digital camouflage camouflage design military camouflage

Abstract. Military camouflage is one of the critical measures taken by some key military forces to disguise weapons and facilities, military projects and combat fighters. Digital camouflage is a novel form in this field. Preliminarily verified by Edge Detection, one method is proposed to digitize large- spot painting patterns, to generate random spot-modification and richer patterns.

1. Introduction

Camouflage is the technology to change the color, pattern and distribution characteristics of the target surface, with the application of dyeing, painting and other materials, which is easy to process, quick in effect and low in cost. Currently, there are three categories, i.e. protective, distortive and imitative painting patterns. The distortive camouflage is to segment and distort the regular outline of the target by utilizing irregular multi-color patterns, with some spots consistent with and the others contrasting to the background. It is normally employed to disguise weapons and facilities in multi-color mottled settings [1]. Digital camouflage refers to the complicated painting patterns, which is generated by computer and composed of rectangular painting pixels with different sizes. It is also known as pixel camouflage, digitized camouflage or mosaic camouflage due to its similarity to the randomly printed output of pixels in different colors [2]. Digital camouflage first appeared in Canada in 1995 and was officially adopted by Canadian Army in 1997. CADPAT TW entered into trial in 1998, followed by the research and development of urban and desert battledress, which ran through all the tests and was granted the patent in the year of 2001. Tests run by the Canadian National Defense Research Base revealed that at the range from 50m to 300m, the disguise effect of digital camouflage battledress is 45% higher than the Olive-Green, and the detecting distance reduced by 35%. Likewise, NATO field test indicated that digital camouflage was obviously superior to the U.S. jungle, German small-spot and U.K. distortive [3]. Later, the employment of digital camouflage by the Royal Canadian Air Force and Navy also obtained good effectiveness. Jungle, urban and desert camouflage battledress were sequentially developed by the U.S. Armed Forces. Some other countries like Finland and Australia produced their own digital camouflage battledress [4]. China began late in this filed. In addition to the military battledress, some weaponry with digital camouflage demonstrated in the Military Parade on the 60th Anniversary National Day indicated the employment of digital camouflage in the Chinese Armed Forces. Nevertheless, basic research concerning the CAD design of digital painting patterns still remains to go further.

In terms of the design of digital painting patterns, there is no unified and definite conclusion so far [1~5]. This paper tries to propose one method to convert the large-spot to digital painting pattern,

with the basic perception that both large-spot and digital are in the same nature of camouflage, the imitative camouflage is achieved by painting the background patterns on the target, and the distortive camouflage by painting the irregular multi-color patterns composed of color block units. Hence, it is feasible to digitize the existing large-spot painting patterns to obtain digital camouflage.

2. Digitization of Large-Spot Painting Patterns

Large-spot painting patterns are composed of segmented and unshaped color blocks, each containing only one single color inside and smooth curves around to segment and distort the original outline of the target. Despite single color inside, each block is filled with many color block units, which are surrounded by dentate curves and contain some spot patterns for modification. Compared with large-spot painting patterns, the blocks of the digital painting patterns are weak in contrast and natural in transition, which is more likely to distract the attention from the observers. The digitizing process is to convert the original large-spot painting patterns to the ones composed of color units. To begin with, large-spot painting patterns are input to array pix (x, y, z) to conduct color space conversion for the purpose of algorithmic operation. Next, the whole large-spot painting pattern is segmented according to the size of color unit, to gain the respective average values of color pixel. Then the pixel values, either of the whole or of the selected part, are replaced by the computed average values. And finally, the digitized output is displayed. The procedure is shown in Fig. 1.

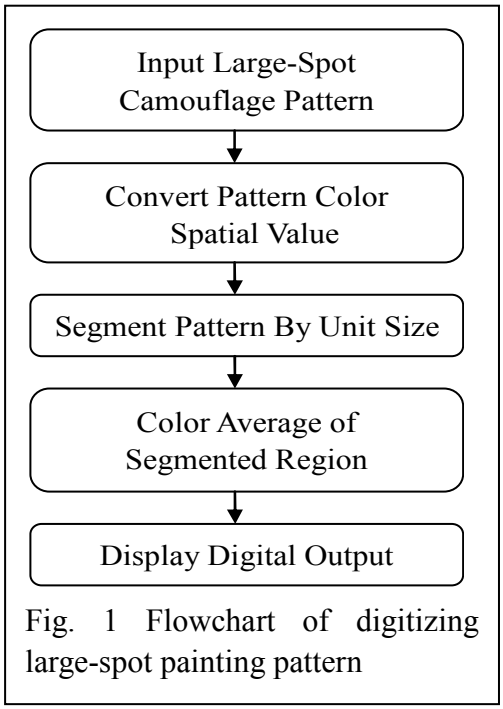

Fig. 1 Flowchart of digitizing large-spot painting pattern

The computed outcome shows that the original large-spot painting pattern (shown in Fig. 2) is segmented to pattern composed of color block units (shown in Fig. 3) surrounded by dentate boundaries.

However, it can be found that many new color blocks appear in Fig. 3, which did not exit and are not identical in color with the original large-spot pattern. In this paper, they are named as "newly-emerging spots", which require to be processed to avoid future trouble in painting.

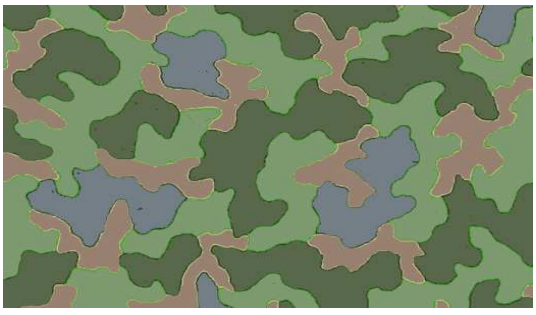

Fig. 2 Original large-spot painting pattern

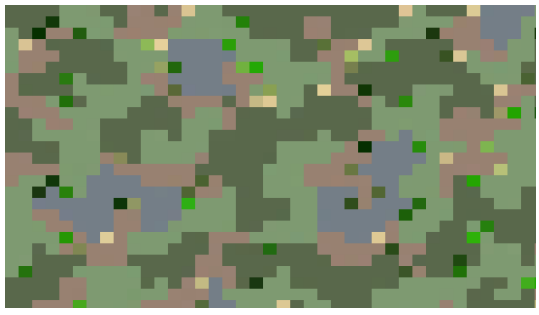

Fig. 3 Digitized painting pattern

3. Processing of "Newly-Emerging Spots"

These "newly-emerging spots" result from the two (or even more) color averages on the edge of the large-spot painting patterns when segmented by color block unit. In fact, they play important roles in enriching digital painting patterns and enhancing pattern randomicity. The processing procedure is to locate them first by comparing each segmented block of the whole pattern or of the

selected part with the existing color. Then identify one after another to check if the color of the segmented block is identical with at least one of the existing spot colors. If not, a random number from 1 to n (n stands for the number of painting color kinds) is generated, according to which the corresponding color is given to the segmented part. Complete the identification process to cover all "newly-emerging spots", which is named as "spot modification" in this paper (shown in Fig. 4).

Owing to the additional randomicity while processing the "newly-emerging spots", different patterns are generated in the final output, especially on the edging parts of different color block units. These new patterns enable the large-spot to segment and distort the regular outline of the target, and at the same time enhance the disruptive effect by their diversity and variability.

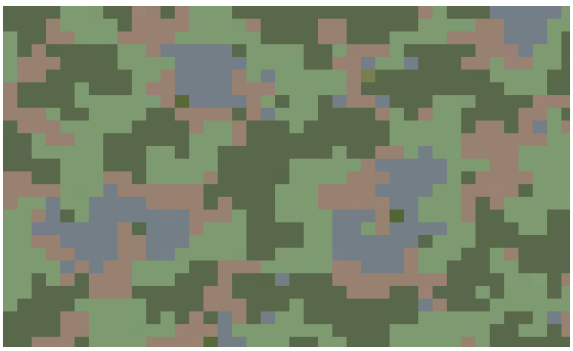

Fig. 4 Digitized painting pattern with "newly-emerging spots" modification

4. Camouflage Effectiveness Simulation Test by Edge Detection Method

To make the preliminary assessment of the camouflage effectiveness generated by the proposed method, the original large-spot and digitized painting patterns are respectively set into the same background (shown in Fig. 5 and 6). And Edge Detection method is applied to make the assessment.

Fig. 5 Original large-spot painting pattern

Fig. 6 Digitized painting pattern

In the digital image processing technology, Edge Detection method intends to extract the target boundaries from the background to separate the target. In this case, both the large-spot and digital painting patterns are required to possess the ability to segment and distort the straight outline of the original target. The main operators involved are Sobel, Roberts, Prewitt, Log and Canny. Fig. 7 and Fig. 8 respectively demonstrate the result of large-spot and digital painting patterns operated by Sobel, and Figure 9 and 10 by Canny. All the rectangular outlines are segmented and distorted, which reveals that camouflage effectiveness is somewhat achieved by both. However, with the comparison between Fig. 7 and 8, large-spot painting pattern still retains some large-spot patterns while the digital does not when operated by Sobel.

The comparison between Fig. 9 and 10 shows that, when operated by Canny, the large-spot presents less quantity and larger size than the digital, which implies, from the Edge Detection point of view, that the latter is better in camouflage effectiveness.

Fig.7 Large-spot painting pattern operated by Sobel

Fig. 8 Digital painting Pattern operated by Sobel

Fig. 9 Large-spot painting pattern operated by Canny

Fig. 10 Digital painting pattern operated by Canny

5. Conclusion

The generation of digital painting pattern is the worldwide focus in its field. Based on the principle of large-spot painting pattern, either by segmenting the whole large-spot painting pattern into color block units, or by averaging the colors of each segmented unit in selected parts, the proposed method successfully digitizes the large-spot painting patterns, eliminates the "newly-emerging spots" by randomly painting them the same color as the original spots, and enriches the patterns with the random modification spots. Edge Detection test also preliminarily verifies that digital camouflage method is able to segment and distort the original regular straight outline of the target, and weaken the visibility further for better integration into the background settings.

A Wavelet Kernel-Based Support Vector Machine for Communication Network Intrusion Detection

Ying Zhan

School of Mathematics &Computer Science, Jiangxi Science &Technology Normal University, Nanchang 330038, China

zhanyingg@sina.cn

Keywords: wavelet kernel, data mining methods, communication network, intrusion detection.

Abstract This study is to propose a wavelet kernel-based support vector machine(SVM) for communication network intrusion detection. The common intrusion types of communication network mainly include DOS, R2L, U2R and Probing. SVM, BP neural network are used to compare with the proposed wavelet kernel-based SVM method to show the superiority of wavelet kernel-based SVM. The detection accuracy for communication network intrusion of wavelet kernel-based SVM is 96.67 %, the detection accuracy for communication network intrusion of SVM is 90.83%, and the detection accuracy for communication network intrusion of BP neural network is 86.67%.It can be seen that the detection accuracy for communication network intrusion of wavelet kernel-based SVM is better than that of SVM or BP neural network.

Introduction

In the few years, lots of data mining methods have been applied to communication network intrusion detection because of the advantages of discovering useful knowledge from large data sets[1-4]. SVM is based on statistical learning theory and executes structural risk minimization, thus it can provide better generalization ability than the conventional methods[5], such as artificial neural network which uses the empirical risk minimization[6,7]. This study is to propose a wavelet kernel-based SVM for communication network intrusion detection.

120 testing samples from KDDCUP99 datasets are employed to study the communication network intrusion detection performance of wavelet kernel-based SVM. The common intrusion types of communication network mainly include DOS, R2L, U2R and Probing. SVM, BP neural network are used to compare with the proposed wavelet kernel-based SVM method to show the superiority of wavelet kernel-based SVM.

The detection accuracy for communication network intrusion of wavelet kernel-based SVM is 96.67%, the detection accuracy for communication network intrusion of SVM is 90.83%, and the detection accuracy for communication network intrusion of BP neural network is 86.67%. It can be seen that the detection accuracy for communication network intrusion of wavelet kernel-based SVM is better than that of SVM or BP neural network.

Wavelet kernel-based SVM

SVM is based on statistical learning theory and executes structural risk minimization, thus it can provide a better generalization ability than the conventional methods, such as artifical neural network which uses the empirical risk minimization.

Given a training set $\{(x_1,y_1), (x_2,y_2), \ldots, (x_n,y_n)\}$, where $x_i \in R^n$ denotes the ith input vector and the corresponding target denotes $y_i \in \{+1,-1\}$, the margin between the input data in the high-dimensional feature space can be maximized to be $1/\|w\|$.

The classifier function of SVM is described by

$$f(x) = w' \cdot \varphi(x) + b \tag{1}$$

The optimal classifier function of SVM can be gained by minimizing the quadratic problem:

$$\frac{1}{2}\|w\|^2 \tag{2}$$

Subject to the constraints $y_i(w' \cdot \varphi(x_i) + b) \geq 1$. We introduce the positive slack variables ξ_i and the optimization problem can be transformed into the minimizing the following formula:

$$\frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n}\xi_i \tag{3}$$

Subject to the constraints $\begin{cases} y_i(w' \cdot \varphi(x_i) + b) \geq 1 - \xi_i \\ \xi_i \geq 0 \end{cases}$, where C denotes the positive constant parameter.

Then, SVM is trained as a Lagrange optimization problem by introducing the Lagrange multipliers:

$$W(a) = \sum_{i=1}^{n}\alpha_i - \frac{1}{2}\sum_{i,j=1}^{n}\alpha_i\alpha_j y_i y_j x_i' x_j \tag{4}$$

Subject to the constraints $\sum_{i=1}^{n}\alpha_i y_i = 0$ and $\alpha_i \geq 0$, where α_i is the Lagrange multiplier. The above formula can be transformed into the following formula:

$$W(a) = \sum_{i=1}^{n}\alpha_i - \frac{1}{2}\sum_{i,j=1}^{n}\alpha_i\alpha_j y_i y_j k(x_i, x_j) \tag{5}$$

Subject to the constraints $\sum_{i=1}^{n}\alpha_i y_i = 0$ and $\alpha_i \geq 0$. In the above formula, $k(x_i, x)$ is the kernel function, and the value of $k(x_i, x)$ equals to $\varphi(x_i) \cdot \varphi(x)$, which is described by

$$k(x_i, x) = \varphi(x_i) \cdot \varphi(x) \tag{6}$$

where $\varphi(\cdot)$ denotes the transformation function. The decision function of SVM is described by

$$f(x) = \text{sign}\left[\sum_{i=1}^{n}\alpha_i y_i k(x_i, x_j) + b\right] \tag{7}$$

where $k(x, x_i) = \exp\left(\frac{-\|x_i - x\|}{2\sigma^2}\right)$, σ is the width of the kernel function. Here, the Morlet wavelet kernel $\Theta(x) = \cos(1.75x)\exp\left(-\frac{x^2}{2}\right)$ is employed as the wavelet kernel function of SVM. Thus, the corresponding wavelet kernel function is

$$k(x,x') = \prod_{j=1}^{m}\left(\cos\left(\frac{1.75\left(x_j - x_j'\right)}{a}\right)\exp\left(-\frac{\left\|x_j - x_j'\right\|^2}{2a^2}\right)\right) \tag{8}$$

Finally, the classification function of wavelet kernel-based SVM can be written as

$$f(x) = \mathrm{sign}\left[\sum_{i=1}^{n}\alpha_i y_i \prod_{j=1}^{m}\left(\cos\left(\frac{1.75\left(x_j - x_{ij}\right)}{a}\right)\exp\left(-\frac{\left\|x_j - x_{ij}\right\|^2}{2a^2}\right)\right) + b\right] \tag{9}$$

Experimental analysis for communication network intrusion detection by using wavelet kernel-based SVM

120 testing samples from KDDCUP99 datasets are employed to study the communication network intrusion detection performance of wavelet kernel-based SVM. The common intrusion types of communication network mainly include DOS, R2L, U2R and Probing.

SVM, BP neural network are used to compare with the proposed wavelet kernel-based SVM method to show the superiority of wavelet kernel-based SVM.

Fig.1 gives the communication network states of 120 testing samples, where normal state, DOS, R2L, U2R and Probing are denoted as "1~5". Fig.2 gives the detection results for communication network intrusion of wavelet kernel-based SVM, and the detection accuracy for communication network intrusion of wavelet kernel-based SVM is 96.67%. Fig.3 gives the detection results for communication network intrusion of SVM, and the detection accuracy for communication network intrusion of SVM is 90.83%. Fig.4 gives the detection results for communication network intrusion of BP neural network, and the detection accuracy for communication network intrusion of BP neural network is 86.67%.

It can be seen that the detection accuracy for communication network intrusion of wavelet kernel-based SVM is better than that of SVM or BP neural network.

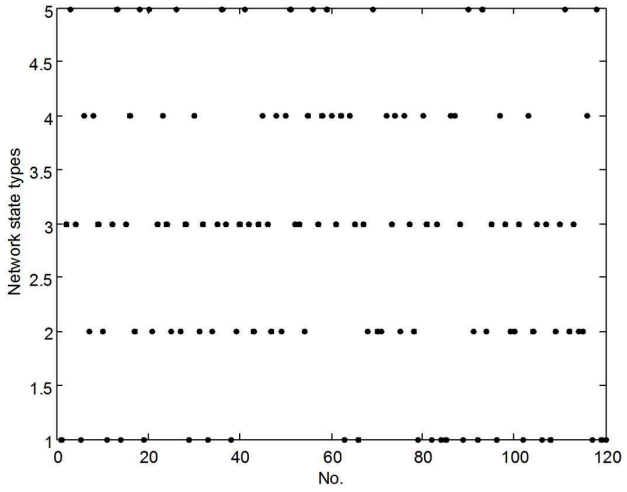

Fig.1 The communication network states of 120 testing samples

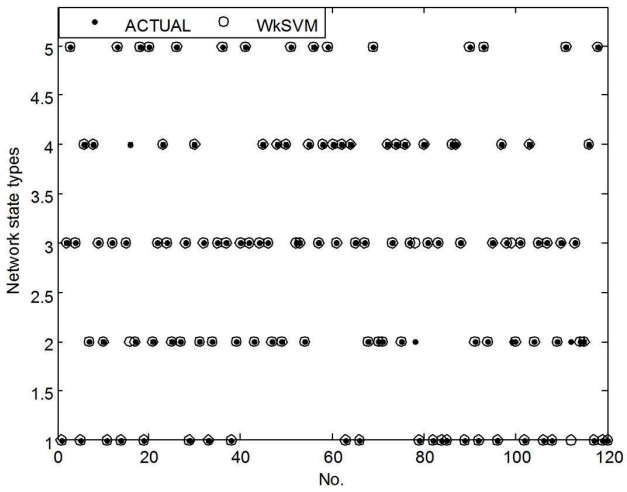

Fig.2 The detection results for communication network intrusion of wavelet kernel-based SVM

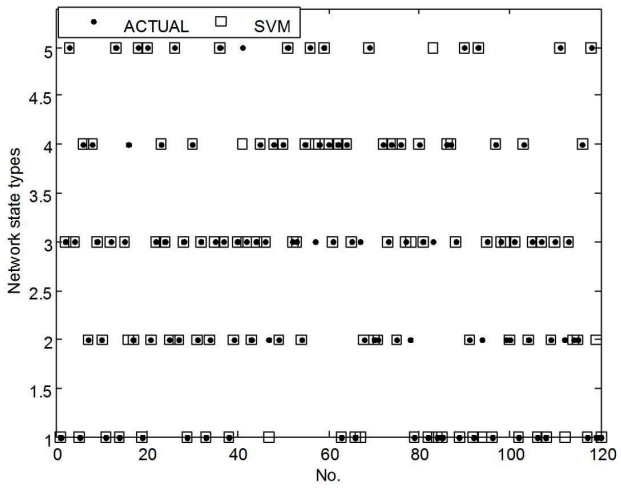

Fig.3 The detection results for communication network intrusion of SVM

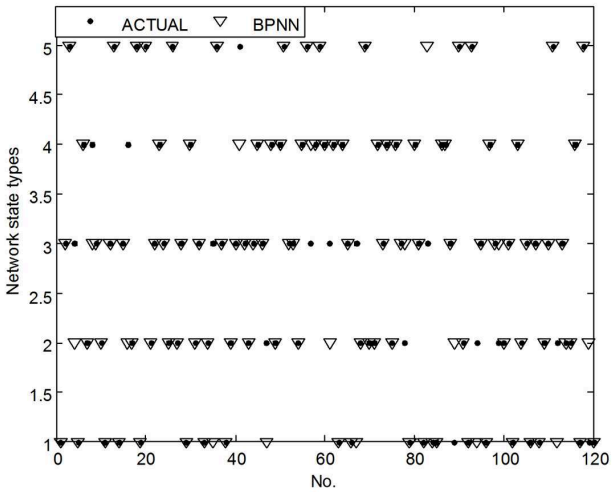

Fig.4 The detection results for communication network intrusion of BP neural network

Conclusion

This study is to propose a wavelet kernel-based SVM for communication network intrusion detection. 120 testing samples from KDDCUP99 datasets are employed to study the communication network intrusion detection performance of wavelet kernel-based SVM. The detection accuracy for communication network intrusion of wavelet kernel-based SVM is 96.67%, the detection accuracy for communication network intrusion of SVM is 90.83%, and the detection accuracy for communication network intrusion of BP neural network is 86.67%. It can be seen that the detection accuracy for communication network intrusion of wavelet kernel-based SVM is better than that of SVM or BP neural network.

Keywords: G-XML; GIS; Attendance Management System; PHS.

Abstract. This paper puts forward the composition of geospatial information and its definition. The author designed and implemented the attendance management system based on Micro-cellular and the geographic information system (GIS) technology. The function of the geographic information system (GIS) was achieved by transforming Japan Geographical Survey Institute's Digital Map 2,500 base plate data into G-XML data. The function of location information system was accomplished according to micro-cellular mobile terminal-in the GIS's Real-time positioning and tracks. At last, the attendance management system based on micro-cellular and GIS technology was implemented by comparing the work schedule with the mobile tracks of its related mobile handheld terminals.

Introduction

Recently, many companies have introduced a variety of attendance management system. For example, IC card accesses control system, IC card attendance management system [1], radio frequency identification RFID card attendance management system [2]. The applicable object is the attendance of employees at fixed work time and fixed work place. However, when work time and work place change, the problem of employees' attendance is still difficult to resolve. The attendance management system is based on the combination of PHS (Personal Handy-phone System) location and geographic information system, it makes the information query function which includes where the holder is at a time become true. According to comparing the field operations staff work schedule (place, time) which was pre-entered in the database with the trajectory (place, time) of PHS (Personal Handy-phone System), the attendance management system automation is achieved.

The Components OF Attendance Management System based on Mobile Handheld Location Information

The attendance management system which is based on mobile handheld location information consists of the following components:

Mobile Handheld (such as PHS)

Micro-cellular base station

Mobile Handheld location information service center

Attendance Management System

Terminal PC

Mobile Handheld location information service center sometime is responsible for the timely and regular collection of Mobile Handheld location information (longitude, latitude coordinates) and sends them timely and regularly to attendance management system. According to the demand of PC side for real-time and regular employees' attendance, the attendance management system is responsible for sending requests for information about location of the current mobile handheld to

locate information service center timely and regularly, receiving mobile handheld location information (longitude, latitude coordinates) at a time from service center timely and regularly, indicating the mobile handset location information in the GIS, and transmitting it to the Terminal PC. At the PC side, the terminal PC sends the mobile handheld's attendance requirements to the Attendance Management System, receives the immediate and regular mobile handset location information which is marked on the GIS, then, according to the schedule information which is the same as accepted mobile handset, We can determine the attendance results and achieve attendance management after comparing with time and location.

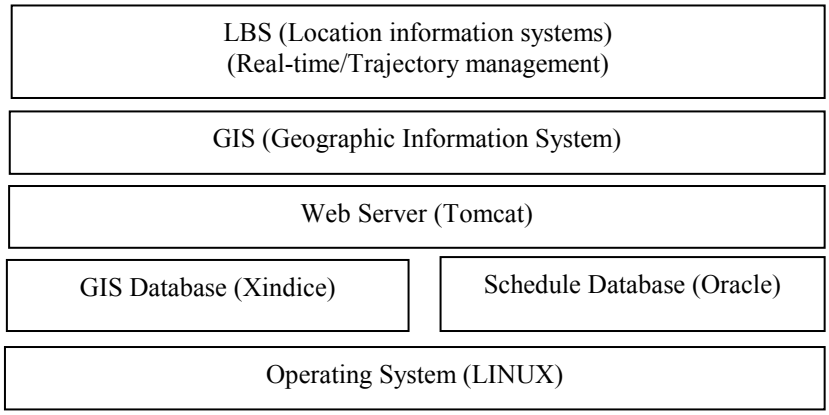

Figure 1. Mobile handheld location information-based attendance management system

The Implementation of Mobile Handheld Location Information System (LBS)

The mobile handheld terminal location was marked in corresponding position on the vector map accurately by the mobile handheld location information system (LBS), which is mainly implemented by the following function modules.

The coordinate conversion function module is responsible for transforming the location of mobile handsets longitude coordinates and latitude coordinates which are received from the mobile handset service center location information into the plane rectangular coordinates. It means that the location of mobile handsets is the actual location of the base station which is the nearest from the mobile handset. The maximum theoretical error of using the base station is 500 meters. Of course, the error is determined by the distance between base stations. The closer the distance between the base stations, the smaller the error.

The figure sector inquiry function module inquires the Xindice database to get the figure pages (G-XML[3] file) which contains the plane rectangular coordinates according to the plane rectangular coordinates of the location of mobile handsets. In order to mark the location of mobile handsets in the central region, the most relevant 9 figures need to be checked out.

The position coordinates conversion function module is responsible for transforming the plane rectangular coordinate of the location of mobile handsets into the coordinates system of the computer screen coordinates.

The figure-depicting function module is responsible for transforming the most relevant 9 figure (G-XML files) into a file group, which is composed of 9 SVG (Scalable Vector Graphics) files, and depicting the vector group according to the file group.

The mobile handset location identification module is responsible for marking the location of mobile handsets (including the date and time information), in corresponding position on the vector map with a small icon.

The Attendance Management System

The Preconditions for achieving this system are as follows: First, employees switch on the mobile handsets and set the location information query function to be effective status; Second, the enterprise of attendance management system and the mobile handheld location information service center sign the contract as follows: the center of location information service should collect location information of the mobile handheld terminal regularly and irregularly and send them to the enterprise timely.

Collecting mobile handset location information regularly is that the service center of mobile handset location information collects the location information of mobile handset in a specified time interval everyday. For example, at 08:00 am~18:00 pm from Monday to Friday, collecting location information of the mobile handheld terminal one time every 20 minutes. For one of the mobile handsets, the location information of mobile handsets needs to be collected 31 times regularly everyday.

Collecting mobile handset location information irregularly is that the service center of mobile handset location information collects the required location information of mobile handset instantly according to the temporary requirements from the side of attendance management system. For example, the service center of mobile handset location information receives a requirement of attendance management system at 10:17 on Saturday which requires inquiring about the location information of three mobile handsets owned by attendance management system side immediately. Then the service center of mobile handset location information collects the location information of the three mobile handheld terminals soon and sends it to the attendance management system side immediately.

The attendance management system mainly consists of the function modules as follows:

The mobile handset location information request module is responsible for sending the requirement which can obtain real-time location information of mobile handset to the location service center. The sending format is HTTP file, the contents are phone number, request time, request type of the mobile handset and so on.

The mobile handset location information response module is responsible for translating the location information (latitude and longitude, time, etc.) of the mobile handset which is received from the service center of location information into plane rectangular coordinates (time, location). After that, this module inquires GIS databases to obtain the location information (administrative location, etc.) of the coordinates, and inputs the spatial location information (time, administrative position, etc.)to the schedule database of the employee attendance management system.

The schedule management function module is responsible for inserting, updating and deleting the work schedule record of the employee. The work schedule mainly consists of employee names, phone numbers of the mobile handsets, address of workplace, working hours and other projects.

The attendance management function module is responsible for comparing the work schedule with the actual action trajectory (time, location) of the mobile handheld according to the work schedule. If the location of the actual action matches with the schedule address (in the range of allowable error), the attendance result is normal, otherwise, the attendance result is abnormal.

The location-expressing function module of mobile handsets is responsible for expressing the current position and the trajectory of mobile handsets.

The current location expressing function of mobile handsets is responsible for marking the present position of the specific or complex real-time mobile handsets on the vector map.

The mobile trajectory-expressing function module of the mobile handset is responsible for marking the passed location information and time information on the vector map.

Conclusion

The mobile handheld location information attendance management system is an attendance management system based on Micro-cellular technology substantively which has resolved the employees' attendance when work time and work place constantly change.

Ultimately, it can achieve providing services for all the people and all the things at any time (anytime) and anywhere (anywhere) [4]. However, the in depth discussion and consensus standard which is about geographic information system in China have not formed yet. In order to be geared to international standards, the international standards of GIS and LBS (location based on service) should be translated into the Chinese national standard as soon as possible [5].

Keywords: Ad Hoc network; black hole attack; AODV; NS2

Abstract. Mobile Ad Hoc network is a self-composing network with a highly dynamic network topology. Although it has many advantages, there are still some safety problems in it. One of these problems is the black hole attack. The black hole attack is a typical attack to the Ad Hoc network and is also the main threat facing it. In this paper, the safety problems exist in the AODV protocol, which is a kind of routing protocol in the Ad Hoc, has been analyzed in detail. In the meanwhile, an improved Secure Ad Hoc On-Demand Distance Vector Routing called OSAODV has been proposed and realized based on the NS2. Finally, three set of experiments have been made, the results have shown that the OSADOV can avoid the black hole attack very well.

Introduction

Mobile Ad Hoc network is a temporary multi-hop autonomous system that consists of a group of movable nodes with wireless transmitting /receiving devices. At present, there are mainly three kinds of routing protocols applied in the Ad Hoc network. They are Destination-Sequenced Distance Vector Routing (DSDV), Dynamic Source Routing (DSR) and Ad Hoc On-Demand Distance Vector Routing (AODV). AODV is currently the most frequently used protocol. However, without any safety mechanism, AODV is vulnerable to the attack from malicious nodes. The common attacks include the black hole attack, the routing table overflow attack, the information disclosure attack and the energy-depletion attack.

In order to avoid the black hole attack, a lot of solutions have been advanced. A very effective methods was advanced by Hongmei Deng, Wei Li and Dharma P. Agrawal, who are in University of Cincinnati. They came up with a protocol which is a security extension of the AODV protocol. In this protocol, each intermediate node is required to send back the nexthop information when it send back a RREP message. Since every source node must send an extra packet to the next hop node of the intermediate nodes, then it surely causes some overhead to the network and increases the network delay. Therefore, there is still some shortcoming in it.

This paper focused on the safety holes in the AODV, discussion of the working process of AODV and analysis of the causes of the black hole attack. Finally an improved solution was proposed based on the existing solution to the black hole attack. A series of experiments have been made and the results shown that this method is somewhat effective. Of course, as a result of personal knowledge and information Limited, there still may be some shortcomings in this paper.

Ad Hoc On-Demand Distance Vector Routing

AODV is a common on-demand protocol of the Mobile Ad Hoc network. It includes the route discovery and route maintenance functions.

1A node disseminates a RREQ when it determines that it needs a route to a destination and does not have one available. The node that receives the RREQ first creates or updates a route to the previous hop without a valid sequence number. It then checks to determine whether it has received a RREQ with the same Originator IP Address and RREQ ID within at least the last PATH_DISCOVERY_TIME. If such a RREQ has been received, the node silently discards the newly received RREQ, otherwise it replies with a RREP message. Once the RREP received, the process of route discovery will be completed and the routing information will be recorded.

2A node may offer connectivity information by broadcasting local Hello messages periodically. If, within the past DELETE_PERIOD, it has received a Hello message from a neighbor, and then for that neighbor does not receive any packets (Hello messages or otherwise) for more than ALLOWED_HELLO_LOSS * HELLO_INTERVAL milliseconds, the node should assume that the link to this neighbor is currently lost. When links break, AODV causes the affected set of nodes to be notified so that they are able to invalidate the routes using the lost link and repairs the link.

The Secure Problem and Black Hole Attack exist in AODV

The characteristics of AODV make the Mobile Ad Hoc network be able to dynamically organize network and function well. However, there are some problems hidden in it. Normal operation of this protocol bases on the premise that all the nodes would be cooperative and authentic. Once the malicious node appears, the protocol may be destroyed. It is just this shortcoming of AODV that is taken advantage of by the malicious node to implement attack. Black hole nodes reply a RREP message to all the nodes generated RREQ and claim that they have the “shortest” route to destination. As the malicious nodes usually give a reply without looking up their route tables or comparing the sequence of the destination, their replies often arrive first. After the node which received the RREP message establishes the route according to the RREP message, its routing path includes the black hole nodes as intermediate nodes. Then when the source node sends data, all the packets will be taken in by the malicious nodes. Thus the black hole nodes become “black hole” which will gobble up all the packets and destroy the normal function of AODV, even makes the Ad Hoc network paralysis.

As the Figure 1 shows, node A wants to communicate with C but doesn’t have the valid route to C, so it sends RREQ message. Both B and D receive the RREQ message, then B replies and claims that it has the fresh enough and shortest route to C immediately without checking its route table. A compares the RREP messages from B and D, it chooses B as the next hop to C and then sends data packets to it. Then B discards all of the data packets, as a result, the black hole attack actualizes successfully.

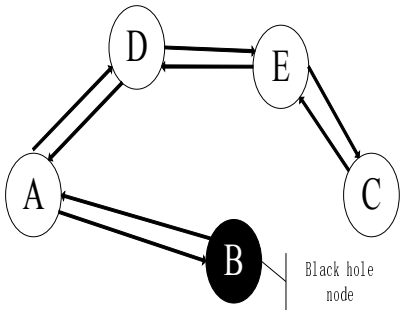

Fig.1. Black hole happens when B is a malicious node

Solution

Existing Solutions.[3]Hongmei Deng, Wei Li and Dharma P. Agrawal, who are in University of Cincinnati, came up with a solution to avoid the black hole attack. Its main idea is that an intermediate node B must put its next hop node C's information into the RREP message which is sent to the source node A when it replies. Then the node A which sent the RREQ message will generate an additional packet to C to check whether the route from the intermediate node exists or not. If the node C really has fresh enough route to the destination node and the intermediate node B, then the node A will trust B as well as its RREP message and start to send data packet to the destination node. If not, it will notify all the nodes in the whole network that B is a black hole node to isolate the node B.

This method still has some problems. Since every source node must send an extra packet to the next hop node of the intermediate nodes, then it surely causes some overhead to the network and increases the network delay.

New Solution. In order to avoid the black hole attack as well as reducing the network delay, the above scheme must be improved. Specific improvement scheme is as follows: two kinds of control packets should be added to the original control messages. They are Confirmation Route Request Message (CRREQ) and Confirmation Route Reply Message (CRREP). Whenever an intermediate node B replies with a RREP message, it must send a CRREQ message to its next hop node C at the same time. Then C which receives the CCERQ message will firstly look up its route table, if it really has the valid route to the destination, it must send a CRREP message to the source node which sends the RREQ message. If not, it just discards the CRREQ message. After receiving both RREP message and CRREP message, the source node starts to send packets to its destination. If only receiving RREP message from an intermediate node, it will send a REEQ message once again and notifies all the nodes to beware of the intermediate nodes from which it receives the RREP message. The new solution can be seen as the following figure 2, figure3 and figure 4.

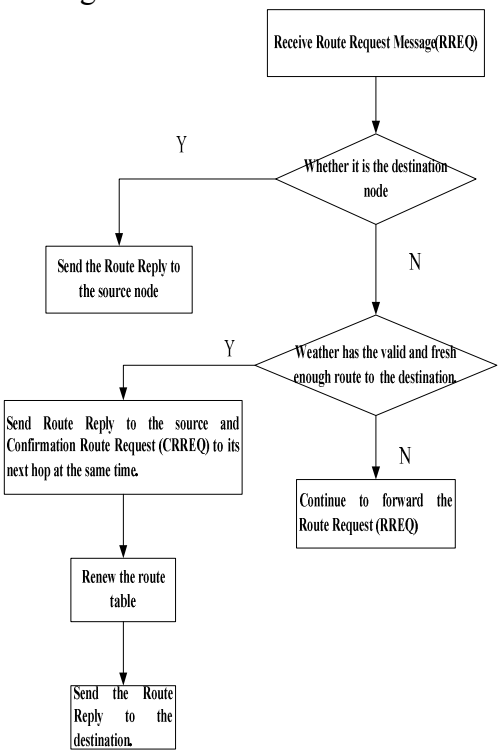

Fig.2. A flow diagram of the process when a node receiving the Route Request Message

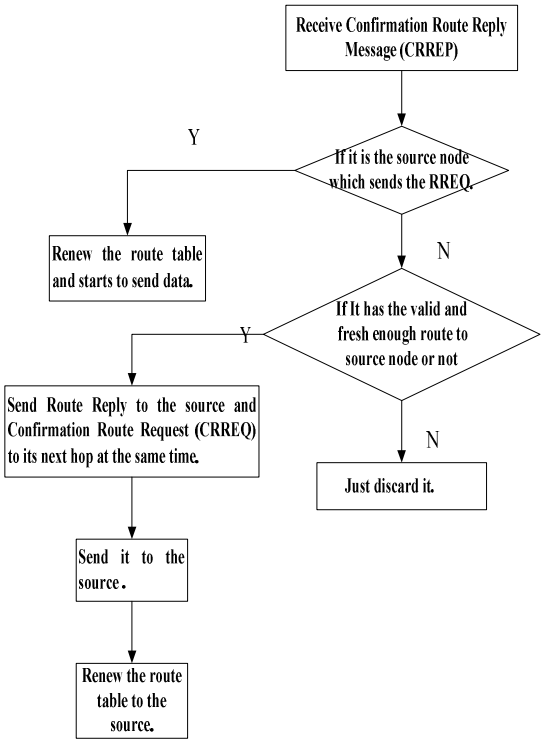

Fig.4. A flow diagram of the process when a node receiving the Confirmation Route Reply Message

.

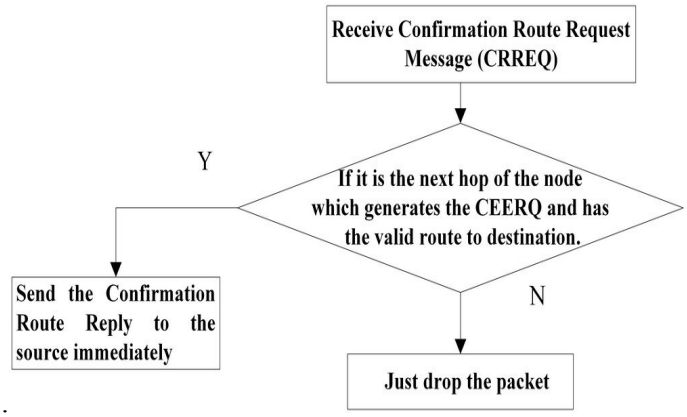

Fig.3. A flow diagram of the process when a node receiving the Confirmation Route Request Message

Realization and Simulation Experiment Based on NS2

In order to achieve the above scheme, two more packets and four more functions must be added. Meanwhile, the original function sendRequest(nsaddr_t dst)should be set one more parameter to carry warning information when a malicious node was found. The main codes are as follow:

```
#define OSAODVTYPE_CRREQ        0x12    // I add
#define OSAODVTYPE_CRREP        0x14    //    I add
#define HDR_OSAODV_CREQUEST(p)    ((struct
hdr_osaodv_crequest*)hdr_osaodv::access(p))
#define HDR_OSAODV_CREPLY(p)    ((struct      hdr_osaodv_creply*)hdr_osaodv::access(p))
struct hdr_osaodv_crequest {
            …
   inline int size() {
  …
   }
};
struct hdr_osaodv_reply {
            …
               inline int size() {
   …
   }
};
void      sendCRequest(osaodv_rt_entry *rt,nsaddr_t ipdst, u_int32_t hop_count,nsaddr_t crqdst,
nsaddr_t crqsrc, u_int32_t crqseq, u_int32_t lifetime);        //      I add
void      sendCReply(osaodv_rt_entry *rt,nsaddr_t ipdst, u_int32_t hop_count,nsaddr_t crqdst,
nsaddr_t crqsrc, u_int32_t crqsequ_int32_t lifetime);
void            recvCRequest(Packet *p);
void            recvCReply(Packet *p);
```

After finishing all of these, I recompiled the NS2 and wrote a tcl script file for verification. In this paper, I used a kind of simulation software named NS2 to simulate the AODV and OSAODV protocols, and compared the mean network delay and packet loss rate when using the different protocols.

The network model includes eleven nodes which distributed in a square field of 1000m×1000m. Every node used the same configuration except the routing protocol, the time of simulation lasted 65 seconds. Three sets of experiments were made when using different data send rates, which ranged from 150 Kb/s to 300 Kb/s. Two used AODV or OSAODV when there was a black hole node in the network, and the last used AODV when there was no malicious node.

After the experiments, the mean network delay was compared. The results showed in the figure 5 and figure 6 in the following.

The Figure 5 showed the mean delay when using AODV and not having malicious nodes or OSADOV protocols and having malicious one node. As we could see, the mean delay of OSADOV was a slightly greater than that of AODV. Extra packets such as CRREQ and CRREP caused longer time to find a valid route.

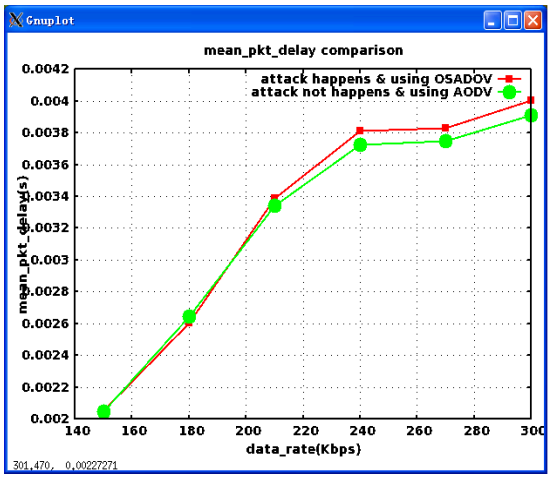

Fig.5. Network delay comparison when using AODV & notexisting malicious nodes and using OSADOV & existing a malicious node

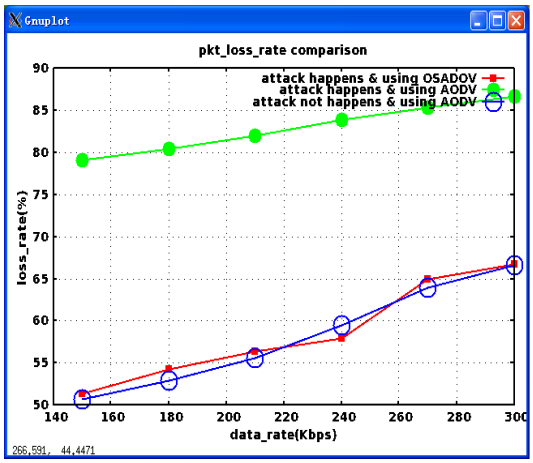

Fig.6. Packet loss rate comparisonbetween three sets of experiments

The Figure 6 showed the packet loss rate of three sets of experiments. When having a black hole node, the packet loss rate of AODV was rather high, while the packet loss rate of OSAODV was just slightly higher than that of AODV when not having malicious nodes

Conclusion

Mobile Ad Hoc network is a developing wireless network and attracts more and more attention. So does the safety problems caused by it own weakness. The basic principle of black hole attack has been introduced in this paper. Besides, an optimization secure protocol called OSADOV has been realized based on the platform NS2 and an Ad Hoc network black hole attack simulation model has been established to make experiments. The results of the experiments have shown that the black hole attack can be effectively prevented when using OSADOV. The packet loss rate can be reduced notably; meanwhile the overhead as well as network delay will not be so large.

Due to personal knowledge and information Limited, there may be some shortcomings in this paper. For example, there is just one black hole node in these experiments. In order to prevent the black hole attack caused by many cooperative nodes more effectively, much work must be done.

Keywords: Three-tier Architecture, Code Template, Automated Code Generation, Generation Engine

Abstract. To solve the problem of user demand dynamics in the development of management information system, an automation development framework based on database is proposed. Software code is generated automatically in the framework that includes three-tier software architecture design, code generation engine, the common code template design and the constraints of the conceptual models design, thus adjusts to change in demand and increases development efficiency. The comparison between the test and analysis shows that the layered architecture can meet the requirements of software applications. The application in the actual project shows that automation development framework can reduce development cost and promote software quality effectively.

Introduction

With the development of information technology, more and more government departments and enterprises use information technology and establish their own Management Information Systems[1](MIS) to improve their management level. During the process of development and practice of MIS, we find user demand dynamics obvious[2] and the user can not present the complete system function demand. It is a cognitive process from vague to increasingly clear, user can understand the function displayed by the software interface well and propose purposeful opinion and suggestions. During the development of MIS based on database, the changes of the user demand may cause the changes of database design.

Based on .NET development platform, this paper presents a MIS software automation development framework which takes the database as the core and is based on code generation engine, paper also describes the implementation of web automation development under the three-tier software architecture, thus in actual application it can improve the efficiency of software development, reduce development cost and able to deal with user changing demand flexibly.

MIS Software Automation Development Framework

The data acquisition, processing and use in MIS can be manifested as taking the database as the core. Therefore, software automation development framework which is oriented management information system and is based on a data model-driven[3] style is implemented in this paper. The MIS software automation development framework consists of four parts, it is shown in Fig. 1.

To apply the framework in MIS development, first, analyze and design the database conception model according to the demand and obtain physical model[4]; then, the code generation engine generates three-tier architecture source code automatically through common code template and database physical model; finally, develop user interface based on the functional demands. MIS software automation development framework mainly works on designing database conception model and writing code for the three-tier architecture with new function.

In the .NET-based platform web system development, the hierarchical approach can be adopted to realize the high cohesion and low coupling[5]. ASP.NET use the simple layers that is code-behind[6] technology. Thus, development efficiency is improved in some degree. The three-tier architecture in MIS automation development framework divides the whole implementation of

system into presentation layer(Web User Interface, Web UI), business logic layer(BLL) and data access layer(DAL). The approach calling these layers one after another has an impact on system performance. Data is transfered among WebUI, BLL and DAL by Entity Layer(Model).

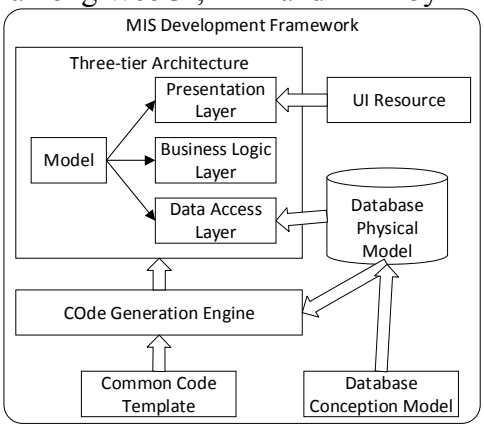

Figure 1 MIS software automation development framework

CodeSmith[7] is a template-based code-generation tool. Through custom templates[8], developer can generate anything from a simple strongly typed collection to an entire application, and do not be required to subscribe to a particular application design or architecture. CodeSmith provides an assembly called the SchemaExplorer which encapsulates all the database objects and supports connection to multiple data sources.

In MIS, database is the core content, its basic database operations consist of four parts, namely INSERT, UPDATE, DELETE and SELECT. The common code model is designed around the four operations. Thus Model, DAL, BLL and WebUI the four common templates are implemented through MIS software automation development framework.

Implementation of Common Code Template

Development framework generates automatically a corresponding source code to each table name of physical database model. According to Table 1 definite relevant rule and obtain source code under the three-tier Architecture. The main generation algorithm pseudo code is as follow:

```
Tables = TableUtilities.FilterTables(Tables); //Obtain table collection from data source
//Obtain code template
CodeTemplate ObjectTemplate = GetCodeTemplate("<template>.cst");
string Directory = OutputDirectory + "\\<directory>\\";//Obtain path
foreache(<table name> in <table collection>){//Generate source code file
    RenderFileUsingProperties("<filename>.cs",true,ref <template>,<data table>)
}
// Generate DALFactory class
RenderFileUsingProperties("DataAccess.cs",true,ref DALFactoryTemplate);
```

Table 1 The rules of code automatic generation

Layer	Rules
Model	“\Model\” + “tablename” + “Info.cs”
DBUtility	“\DBUtility\” + “MySQLHelper.cs”
<xxx>DAL	“\<xxx>DAL\” + “tablename” + “.cs”
IDAL	“\IDAL\”+ “I” + “tablename” + “.cs”
DALFactory	“\DBLFactory\” +”DataAccess.cs”
BLL	“\BLL\” + “tablename” + “.cs”
Web	“\Web\” + “\tablename\” + “<operation>.aspx.cs”

A. Model Template

A model corresponds to a table name in physics database model. Through the model template entity class code is generated, including member variables and relevant get/set method. During the code generation, correspondent relation between the database field type and C# data type is established. The main generation algorithm pseudo code is as follow:

```
foreach(<field> in table){
    // Obtain definition statement of member variable, Called GetCSharpVariableType() and
    // GetCSharpVariableType()
    GetMemberVariableDeclarationStatement(<field>)
}
```

B. DAL Template

DAL template is designed around four operations, that is INSERT, UPDATE, DELETE, SELECT. To separate from concrete database access, the operations are abstracted as a separate interface module IDAL. The design which has nothing to do with the implementation assures the system's expansibility and database's portability as well. During the realization of access to the database, MySQLDAL, SQLServerDAL and OracleDAL common data access templates are provided; the corresponding Helper class is also provided to encapsulate the database operation in DBUtility. In DALFactory, a definition about sealed class implement Abstract Factory pattern is given. Then dependencies are reduced through configuration file and reflection. The main generation algorithm pseudo code about Insert in MySQLDAL is shown in the following:

```
public int Insert(<Model Object>){
    createInsertSQL();// Generate insert statement according to filed
    createMysqlParameter();// Generate MySQL param according to field
    //Obtain result by call ExecuteNonQuery() in MySQLHelper class
      MySQLHelper.ExecuteNonQuery(MySQLHelper.ConnectionString, CommandType.Text,
strSQL, _params);
}
```

By similar approach, MySQLDAL provides Update, Delete, Get<table name>, Get<table name>All, Get<table name>By<field> etc. to implement data basic operations. At the same time, the template defines the method of execSQLForResult and execSQLNoResult to deal with the special SQL requirement in BLL.

C. BLL Template

BLL is the part which reflects the core value of system structure, mainly concerns with defining business rules and implementing of the business process. Therefore, BLL template designs basic data operation business logic, which needs to be implemented in BLL module. The main generation algorithm pseudo code is as follow:

```
DataAccess.Create< tablename >();//Create instance of I<table name> interface
public static int Insert(<tablename >Info){ //Basic business handle : Insert
    _dal.Insert(<tablename>Info); //DAL handle: Insert
}
```

Similar with IDAL, BLL also provides implementation of data basic operation with approaches, including: Update, Delete, Get<table name>, Get<table name>All, Get<table name>By<field>, execSQLForResult, and execSQLNoResult.

D. WebUI Template

WebUI is the layer needs to write the most lines of code in MIS development framework, including script files, style file, image files and media files etc.. Therefore the template design only generates addition, modification, delete, querying (listing) these four standard pages in which the three basic Web controls （Button, TextBox, GridView）are adopted. Here Add.aspx and Add.aspx.cs main generation algorithm pseudo code is as follow:

```
foreach(<field name> in <field collection>){//Create Add.aspx
    "<asp:TextBox ID="TB< field name >" runat="server"></asp:TextBox>"
}
<asp:Button ID="Button1" runat="server" Text="OK" onclick="Button1_Click" />
//Create Add.aspx.cs
protected void Button1_Click(object sender, EventArgs e) {//Button event handle
    create <table name>Info object _obj;
    foreach(<field name> in <field collection>){
        object assignment
    }
```

<table name>.Insert(_obj) //execute Insert method in BLL
}

The design of creating other pages is basically the same, using GridView control to show data list in query interface.

Application Analysis

A. Performance analysis

The hierarchical design of MIS development framework reduces coupling and generates code automatically, which enables developers to focus more on business logic and implementation of interface display in the process of development, but it also imposes a performance penalty. A comparison experiment is carried out between system code generated from the framework and non-layered code. Aiming to MIS with the database as the core, there are four operations are made out to test.

Test environment for this paper: CPU Core i5-3230M, Memory 4GB, HD 1TB，Web platform .NET Framework4.0 and VisualStudio2012（built-in IIS Express)，Database MySQL. To different implementation way execute data-operation test of different magnitude record collection (10, 100, 1000, 10000, 100000, 1000000). Test result is shown in Table 2 and Table 3.

Table 2 MIS development framework layered architecture

Record collection	Average of ten times [second]			
	Insert	Update	Delete	Select
10	0.00540402	0.00810554	0.00620414	0.00140159
100	0.05083377	0.04683117	0.04252775	0.00299833
1000	0.5261511	0.43699134	0.39066053	0.01651062
10000	5.10500705	4.2398297	3.71547944	0.17111395
100000	44.27965447	36.56134138	38.97659102	1.39092815
1000000	354.5257415	383.3854963	298.7542193	16.20891126

Table 3 ASP.NET code-behind architecture

Record collection	Average of ten times [second]			
	Insert	Update	Delete	Select
10	0.00468688	0.00360248	0.00310217	0.00120084
100	0.01562204	0.02071429	0.01661065	0.00250166
1000	0.12096958	0.15670435	0.12368224	0.01140744
10000	1.12094686	1.42805171	1.1365568	0.11957963
100000	11.15363613	14.68989249	11.5336883	1.27084694
1000000	132.2544559	154.6008215	126.9883284	12.06444252

The comparison of tested data is shown in Table 4

Table 4 Result

	Insert	Update	Delete	Select
10	1.15	2.25	2	1.17
100	3.25	2.26	2.56	1.2
1000	4.35	2.79	3.16	1.45
10000	4.55	2.97	3.27	1.43
100000	3.97	2.49	3.38	1.09
1000000	2.68	2.48	2.35	1.34
Average	3.33	2.54	2.79	1.28

Table 4 illustrates that Insert, Update and Delete operational performance reduces to 200 to 300 percent, Select operational performance reduces to 30 percent. Considering that the query operation accounts for the large proportion in the real application of MIS, the code generated through the development framework is able to meet the demand.

B Case Study

The paper presents that software automated development framework has already been successfully applied in Jiujiang agricultural products monitoring platform system. To obtain citywide agricultural products data, step up monitoring and improve time effect of data, Jiujiang agricultural products monitoring center needs to establish an effective data transfer, analysis and statistical system.

First, communicate with consumer to get initial demand, according to which build a conceptual database model and generate quickly prototype system through development framework. Second, by using and test, consumer clarifies demand; a more satisfied demand analysis will be obtained after many repetitions. Finally, take this as milestone proceed into stable system development. Through code statistics tool, the number of lines of all software code and lines of automatically generated code are obtained respectively. Statistics result is shown in Table 5.

Table 5 Percentage of automatically generated code

	Model	DAL	BLL	WebUI	Software
total	5726	16594	6921	15502	44743
generation	5726	14962	5171	9658	35517
percentage	100%	90.1%	74.7%	62.3%	79.4%

The code of Model is generated automatically 100 percent, the code of DAL is generated automatically 90.1 percent, the code of BLL is generated automatically 74.7 percent, and the code of WebUI is generated automatically 62.3 percent. The average automatic generation rate is 79.4 percent. According to the above statistics, application of the software automated generation technology presented in this paper improves development efficiency, makes developer focus on solving main problems of demand and respond timely when user's demand changed, thus debases the workload of developer.

Conclusions

This paper presents a software development automation technology oriented MIS, and gives a development framework not only is suitable for medium or small MIS but also can respond to user dynamic demand. By testing and analyzing, we find the data which accounts for a large portion in MIS has little querying performance loss, test results show that it has better performance. The analysis of the actual application results shows that it has better practicability and maneuverability.

Keywords: Wireless sensor network; congestion control; RED

Abstract. As the study on and promotion of wireless sensor networks (WSN) are deepening, people have increasingly higher requirements for the transmission speed and transmission performance of wireless sensor networks. Network congestion is an important factor of the transmission performance of a network, so congestion control becomes a hot research topic in the studies on the improvement of WSN services. Based on the study on WSN congestion control mechanism, this paper proposes an adaptive congestion control algorithm and simulates the algorithm. The simulation result shows that this algorithm can ensure stable network performance.

Introduction

Compared with the congestion caused by performance degradation which results from insufficient resources in traditional networks, the coexistence of various network environments is a key problem in WSN congestion control mechanism. How to keep smooth data transmission among multiple networks has become a significant bottleneck in WSN development. Therefore, how to solve the congestion problem of WSN is a major direction of the future network studies. This paper improves existing congestion control methods to adapt to the changeable WSN environment.

Wireless sensor networks and their congestion control mechanism

1. Causes of WSN congestion

The causes of WSN congestion vary with different modes of network transmission.

(1) Congestion of wired network transmission

Its cause is not essentially different the cause of traditional network congestion. Network performance declines because of insufficient storage space, limited processor capacity and narrow bandwidth. When a subnet forwards too many packets, the load exceeds the network capacity and congestion occurs, which is manifested as longer transmission delay, packet loss and performance decline, etc.

(2) Congestion of wireless network transmission

The wireless network environment is characterized by limited bandwidth, bit error rate, high packet loss rate, long time delay, random loss of data, linkage interrupt and limited energy. The congestion of wireless networks is mainly caused by the lack of efficient mechanism of error processing, the lack of effective recovery of unexpected errors, frequent switching of network transmission data as well as frequent changes in the locations of mobile terminals and destination node.

(3) Congestion of hybrid network transmission

A WSN is a hybrid network, including local area networks composed of different devices, in addition to wired networks and wireless networks. The complex network environment leads to diverse causes of congestion. The congestion of hybrid networks is manifested as data package loss when transmission data are switched in different networks, data piling up when data is transmitted from a high speed network to a low speed network, waste of bandwidth when data is transmitted from a low speed network to a high speed network, etc.

2. Manifestations of WSN congestion

When the load of a network increases to a certain degree, the available resources on the network decrease, which causes network congestion or even collapse. In a complex network environment, there may be diverse causes of WSN congestion or collapse, and congestion or collapse may occur even though the above conditions are met. The failure of packets to arrive at the source and the loss of data packages in network transmission are the main manifestations of congestion and collapse. Moreover, TCP's repeated transmission of the data packages which are not yet lost may also lead to collapse. Due to the particularity of WSNs, it is cannot be determined under what circumstances data packages do not to arrive, so repeated transmission is more likely to result in WSN congestion.

3. Evaluation criterion of congestion control algorithms

A criterion is required to evaluate the performance and practical significance of congestion control algorithms. An algorithm is evaluated from its feasibility, reliability and execution efficiency, and it is usually analyzed from the aspect of the user, i.e., to evaluate whether the congestion control algorithm is effective through the processing capability of the end system, and from the aspect of the system, i.e., the feasibility and effectiveness of the algorithm.

4. Congestion control strategy

Due to the special environment of WSN, there is no specific and concrete algorithm to effectively solve the problem of congestion control. The study on, analysis and comparison of traditional congestion control algorithms indicate that Random Early Detection (RED) algorithm has a good performance in wired and wireless network environments. With the combination of the advantages of RED algorithm, this paper proposes an improved adaptive congestion control algorithm—a RED algorithm based on semi-normal distribution function, which can effectively solve the WSN congestion control problem in the wired, wireless and hybrid network environments.

Study on congestion control queue

1. Queue management

A new concept of queue management is developed after the queue management based on tail drop algorithm is improved. That is, queue management is a management mechanism of transmission control on the packets of router in the form of queues, and it is composed of data packet forward and buffer queue management. Queue management mechanism plays an important role in congestion control, and according to certain principles, determines whether a data package enters the forward queue, i.e., whether a data package is to be dropped.

2. Queue management control strategy

The researchers have studied and improved the queue management mechanism to deal with complex and changeable networks, and have proposed various new methods and strategies. Such studies are embodied in two levels:

(1) Data packet level: Queue management determines the packet drop strategy from the perspective of packet control.

(2) Congestion control at the data flow level: The resources in the buffer area are fairly allocated to each data flow.

3. TCP congestion control mechanism

The studies show that the maximum bandwidth B available to data flows in congestion control phase is

$$B < \frac{1.45 \times M}{R \times \sqrt{P}} \quad (1)$$

Where, M refers to the maximum segment size, R is the round-trip delay, P is the drop probability of data packages in congestion state. Thus it can be seen that the effective bandwidth available to data flows is proportional to the segment size, but is inversely proportional to the round-trip delay, the drop probability.

In a real network environment, N links share Mmb bandwidth; assuming that each link has identical bandwidth, the bandwidth available to each link is

$$B_n < \frac{M}{N} < \frac{1.45\times M}{R\times\sqrt{P}} \quad (2)$$

The drop probability P of data packages can be derived from the above formula:

$$P < \left(\frac{N}{M}\times\frac{1.45\times M}{R}\right)^2 \quad (3)$$

It can be seen from the above formula that the drop probability of data packages is proportional to the square of the maximum segment size, the square of link number, but is inversely proportional to the round-trip delay. That is, when there are more link connections, the increase in P can release serious network congestion; when there are fewer link connections, the decrease in P can adapt to the mild network congestion.

4. Congestion control algorithm

RED algorithm calculates the drop probability of data packages according to the average queue length, and packets, marks and drops data according this drop probability so as to effectively prevent the congestion of the source. RED adopts FIFO queue scheduling strategy to drop the data packages which have not entered the router yet. However, this algorithm has sensitive parameter setting; the average queue length changes little and the heavy network load likely adds delay jitter; it cannot estimate the severity level of congestion and cannot ensure fair use of bandwidth.

Improvement of WSN congestion control algorithm

Compared with the previous packet algorithms, RED algorithm has improved performance and stability, but poor adaptive adjustment capability. This paper proposes a DRED algorithm based on semi-normal distribution.

1. Improvement strategy

Based on the above analysis of RED algorithm, this algorithm can be improved from the following three aspects:

(1) The drop probability of data packages adjusts dynamically and adaptively with the change in the average queue length to increase network flexibility;

(2) Use curve to describe the drop probability of data packages, reduce the influence of threshold value on P to increase the pass probability of packet;

(3) Adjust P to 1 quickly to avoid entering the drop phase of all data packages when the packet is between the maximum threshold value of the queue length and the buffer size;

2. Algorithm improvement

The fuzzy semi-normal distribution membership function is as follows:

$$u\wedge(\mu)=\begin{cases}0 & \mu\le\alpha\\ 1-e^{-\alpha(\mu-\beta)^2} & \mu>\alpha,\ \alpha>0,\ \beta<0\end{cases} \quad (4)$$

Assuming that μ refers to the average queue length; β is the minimum threshold value, the formula for the drop probability of data packages is

$$P(Q_{av})=\begin{cases}0 & Q_{av}\le Q_{min}\\ 1-e^{-\alpha(Q_{av}-Q_{min})^2} & Q_{av}>Q_{min}\end{cases} \quad (5)$$

When the queue length equals the maximum threshold value, the drop probability of data packages is P_{max}, and thus α is:

$$\alpha=-\frac{Ln(1-P_{max})}{k^2} \quad (6)$$

Where, k is $Q_{max}-Q_{min}$, and the value of α is determined by P_{max}. Thus it can be concluded that the drop probability function of data packages based on semi-normal distribution is as follows:

$$P(Q_{av})=\begin{cases}0 & Q_{av}\le Q_{min}\\ 1-(1-P_{max})^{-\left(\frac{Q_{av}-Q_{min})^2}{k}\right.} & Q_{av}>Q_{min}\end{cases} \quad (7)$$

3. Simulation and performance analysis of the algorithm

To verify the effect of DRED algorithm, three sending endpoints and one receiving endpoints were set in NS2, and each link had the same sending speed and could be adjusted according to the experiment requirements so as to set bottleneck link between the nodes. The following figures are the

specific parameters: P_{max}update time: 0.05S; Q_{min}:100 packets; Q_{max}:300 packets; weight:0.002; buffer size:400 packets; simulation time:50S.

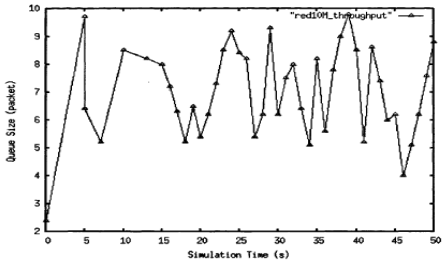

Figure 1 Queue length change in RED algorithm

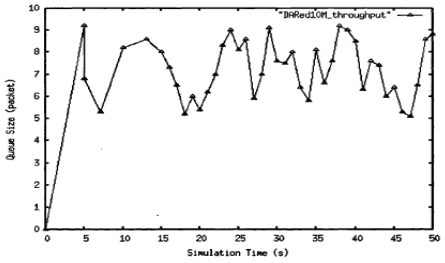

Figure 2 Queue length change in DRED algorithm

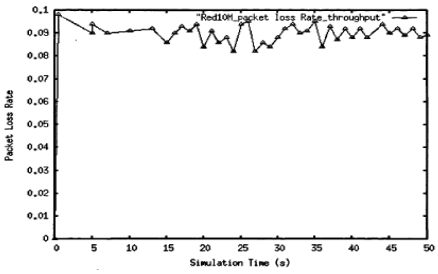

Figure 4 Change in the drop probability of data packages in RED algorithm

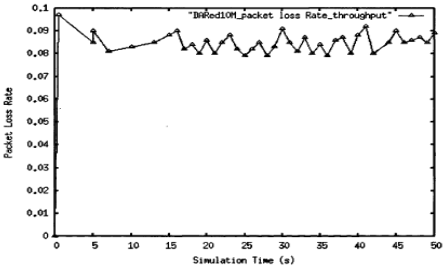

Figure 3 Change in the drop probability of data packages in DRED algorithm

When the sending rate is 10mb/s, DRED algorithm can adjust the drop probability of data packages according to the change in network environment, promptly notify the sending endpoints to change their sending rate and adjust the various parameters in the network so as to maintain the queue length in a faster and better way, prevent congestion, effectively prevent the drop of many data packages, keep good throughput capability and performance and satisfy the complex WSN environment.

Conclusion

This paper conducts a in-depth analysis and study on the complex WSN environment and the causes of WSN congestion, analyzes the application of active queue management mechanism to complex network environments. It also proposes an adaptive control algorithm based on semi-normal distribution, builds a transmission model, and conducts a simulation and a comparative analysis. The simulation and analysis results prove the effectiveness of this algorithm in the adaptive control of WSNs on congestion.

An Approach to Describing Software Logic Model

Xiaoguang An

Department of Information Engineering Jilin Business and Technology College, Changchun, China

34233682@qq.com

Keywords: software logical model, structure of software, security of running software, performance of software

Abstract. This paper proposes the concept of software logical model, the basic idea and the approach of constructing the model. It describes the structure of this model, the ways of expression and the related definitions in detail. At the same time, it has also analyzed the application direction of this model. It discusses the roles playing on the aspects of research and the analysis detailedly, in which this model improves the performance of software, optimizes the structure of software and guarantees the software will run in security. Based on this model, a kind of early security warning mechanism of software is proposed.

Introduction

At present, some security management technologies and products have been developed in the field of computer network security, and many software development models have been advanced and fully discussed. However, there are few studies on software logic models, which affect further studies on the optimization of logical structure, improvement of performance and security of software.

This paper attempts to advance an approach to describing software logic models and aims at using this model to carry out further studies on the optimization, performance improvement of the related software as well as on the security of software operation so as to make computer software better serve customers.

Software logic model

Introduction of the software logic model

From the perspective of software function, any software can be described as a simple model: input—processing—output, as is shown in Figure 1 Diagram of Software Function Model. Input is responsible for acquiring the data necessary for the operation of the software; processing is to process the entered data according to some given rules; then output is to output the processed results.

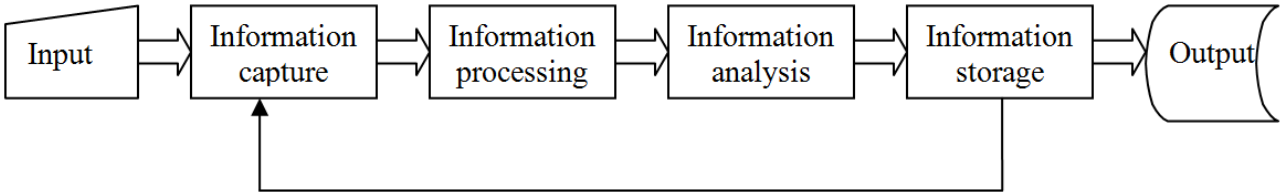

Figure 1 Diagram of Software Function Model

In terms of a specific application program, the ordered arrangement of input, output and processing can make the application program perform its special function. If the program's stable state of waiting for input is defined as State I, the stable state of output completion is defined as State O, and processing is defined as State transition C, then the above model can also be described as State I—State transition C—State O, as is shown in Figure 2 Diagram of Software Logic Model. The ordered arrangement of State I, State transition C and State O fulfils the software function. According to this idea, a program may be considered consist of a state set, a state transition set and a function set.

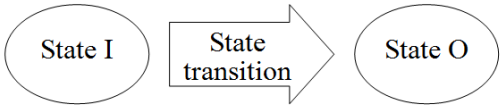

Figure 2 Diagram of Software Logic Model

The state set includes all stable states of an application program, i.e., state; the state transition set consists of all available routes for state transition. All subsets of the set of the staggered and ordered arrangements between state and state transition constitute all possible functions of the program.

The following algorithm can be obtained based on the above study.

Algorithm 1：If the state set of a program is S={s0, s1,…si…, sn-1}, the state transition set is C={ c0, c1, …ci…cm-1 },where cj (si, p0, p1,…pi…, po-1)=sk∈S, p0, p1,…pi…, po-1 are transition parameters; the function set of the program is F={f0, f1,…fi…, fr-1}, where fi is a subset of S⊕C, then the logic model of a program can be defined as follows:

P=(S, C, F), where S is the state set of a program, C refers to its state transition set and F is its function set.

Notes: A⊕B={all subsets of the staggered and ordered arrangements between A and B elements}, where A and B are finite sets.

Expression of the software logic model

According to Algorithm 1, the software logic model can be dealt with in the following way. States can be abstracted as points, and the transitions between different states are abstracted as arcs, then the logic model of a program can be expressed by a digraph. In this way, the studies on software logic model turn into the studies on the digraph, the optimization problem of software structure into the spanning tree problem of the digraph, the software performance problem into the network flow problem and the access control problem of software operation into the isomorphism problem of the digraph. Therefore, digraph and network theories can be used for further studies on the structure optimization, performance and detection of legal operation of software.

After the introduction of the software logic model, this model is then used to carry out quantitative analysis on the optimization, performance and access control of software, and then the expression of the logic model will be handled. With reference to the incidence matrix of digraph, matrix can be used to express software logic model. Algorithm 2 is described as follows:

Algorithm 2：If the software logic model is P= (S, C, F), S={s0, s1,…si…, sn-1}, C={ c0, c1,…ci…cm-1 }, F={f0, f1,…fl…, fr-1}, matrix M(P)=[aij] is the incidence matrix of P, where,

$$a_{ij}=\begin{cases}0, & \text{when there is no transition between } s_i \text{ and } s_j\\ 1, & \text{when there is transition betweens}_i \text{ and } s_j\end{cases}$$

, M is clearly a n×n matrix.

If the cost of transition between different states is considered as weight, then the digraph of software performance and performance matrix can be obtained.

Algorithm 3：If the software logic model is P= (S, C, F), S={s0, s1,…si…, sn-1}, C={c0, c1,…ci…cm-1 }, F={f0, f1,…fl…, fr-1}, matrix Mp(P)=[pij] is the performance matrix of P, where,

$$p_{ij}=\begin{cases}\infty, & \text{when there is no transition between } s_i \text{ and } s_j\\ v, & \text{when there is transition cost between } s_i \text{ and } s_j\end{cases}$$

, Obviously, Mp is also a n×n matrix.

The incidence matrix of the software logic model lays a foundation for the quantitative studies on the relationship among the sub functions of the software function, software structure optimization analysis and performance analysis, software access control and other problems.

After the expression of the software logic model is determined, the relationship among the sub functions of the software function is studied, which is significant for the optimization of software structure as well as for the judgment of whether an operator operate legally in software operation. In order to achieve the above-mentioned aim, the algorithms for describing the relationship among the sub functions are as follows:

Algorithm 4：If ci exists, ci (si, p0, p1,…pi…, po-1)=sk, then si and sk constitute the context of ci, si is the preceding part, while sk is the following part.

Algorithm 5：If the sequence sj0,…sji, sji+1…, sjn exists, where, sji∈S, then sji is the preceding part of sji+1, sji+1 is the following part of sji; if so∈S-{sj0,…sji, sji+1…,sjn} does not exist, and so has the preceding part or the following part in S, then the sequence sj0,…sji, sji+1…,sjn is a maximum ordered sequence of S.

For a specific program, a specific function can actually be understood as a maximum ordered sequence of its state set, and all of its functions belong to the set of all maximum ordered sequences in its state set. Since software operates in strict compliance with the maximum ordered sequences, and if this rule is violated, the software will end in an abnormal state. For example, forced shutdown, logical errors lead to the outage of the software.

Step 1. In software logic model P= (S, C, F), all maximum ordered sequences with S0 as the original state constitute the set of all functions of P, and S0 is the first stable state in the software operation.

The state S in the logic model P= (S, C, F) is abstracted as a point, and transition C is abstracted as a directed arc, then logic model P can be converted into a digraph G.

(1) With S0 as the root node, construct the spanning tree G' of Digraph G;

(2) In G', the nodes in the route from the root node (serving as the initial node) to any leaf node constitute a node sequence. According to Definition 4, this sequence is a maximum ordered sequence of the node sequences of G';

(3) Since G' is the spanning tree of G, the set of node sequences from the root node of G' to each leaf node is equal to the set of all maximum ordered node sequences in G;

It can be concluded from the above description that all maximum ordered sequences of S in the logic model P= (S, C, F) constitute the set of all functions of P.

Step 2. Software operates in strict compliance with the maximum ordered sequences of the state set in the logic model.

(1) Assuming that software operation is not in strict compliance with the maximum ordered sequences of the state set in the software logic model, there must be a state Si which belongs to the software state set. When the software is in the state Si, it does not belong to the maximum ordered sequences of any software state set;

(2) Since all maximum ordered sequences of the software state set S contain the state set S'=S, and Si does not belong to S', Si does not belong to S;

(3) On the basis of (2), it can be concluded that Si is not a stable state in the software state set, so Assumption (1) is false;

(4) The above discussion proves that software operation complies strictly with the maximum ordered sequences of the state set in the software logic model.

In software operation, if transition ci exists, ci (si, p0, p1,…pi…, po-1)=sk, while si and sk are not the maximum ordered sequences of the same software state set, then the software operation is illegal.

Application of the software logic model

With the software logic model, software with complex logical relationship can be abstracted into a digraph, and thus digraph theory can be used to study the logical structure of software. This assumes significance for logical structure optimization, performance improvement as well as operation security of software.

The software logic model can be used to identify the redundant states and calls in software, to integrate software functions so as to achieve their optimization, to predict the software function which is about to run, which is meaningful for fulfilling the pipelining call of software functions, and thus helps improve its operation performance. With increasing importance attached to software security application, this model can also be used to secure legal users' safe access to the system resources and prevent illegal visitors' intrusion in the operation process of software.

Conclusions

Currently, the object-oriented software development technology is the mainstream software development technology, and it encapsulates the details implemented by software, which tends to make software development have integrated components. This tendency accords with the logical structure of the software logic model, and proves the reasonability of this model from the practical perspective of software development. It is worth noting that in C/S software, because the states which constitute the logical structure of software are in a stateful relationship, on the premise of not ignoring the stateful property between the states, the analysis of the logical structure with the software logic model is limited. However, in B/S software, such characteristics as the independence of requests, connectionlessness and statelessness of software make the software logic model very suitable for this kind of software. Therefore, it is very appropriate to use this logic model to represent the logical structure of B/S software. With its convenient use and excellent maintainability and expandability, Web application is becoming the mainstream in the development of application system, which further reflects the value of the logic model.

This paper introduces the concept of the logic model of Web application programs, and presents the related expressions and algorithm rules. This logic model provides a new solution to the performance analysis, structure optimization and security of Web application programs and new development space for our studies on security.

The accuracy of this logic model still needs further improvement. Since Web application programs have big granularity, our further studies will focus on the division of security granularity.

Keywords: Home-Based Community Care for the Old; Mobile web; jQuery Mobile; Software Platform

Abstract. "Empty nest" is increasingly serious and jQuery Mobile (JQM) has become a mainstream UI framework for Mobile web development. According to which phenomenon, formulate 18 kinds of service items according to the practical needs of the old. Build modular interface by means of JQM, and then fill detailed function in each module combining with MySQL database. The content of the database includes service resources and information about the old, which need to be updated in real time. Realize foreground-background communication through SOCK_DGRAM. Results show that the platform can accomplish the prospective service for the old. This mode has low cost and strong scalability, and it is a new socialization care for the old platform which is clear to operate, supporting the use of resources and multi-party benefit.

Introduction

The data shows that the rate of “Empty Nest” reaches up to 49.7% in China and there are even more than 80% in foreign countries [1].The phenomenon of “Empty Nest” is a social issue as well as an symbol of social progress .The old man play an important role in society and their wisdom, knowledge and experience are thought to be great wealth of the society [2]. Therefore, government and people should show solicitude and respect to the old, protect the rights and interests of the elderly, made it achieved for them to get welfare medicine, accomplishment, knowledge and entertainment. We need to help them be healthy in both physical and psychology. What’s more we should make sure the insurance of their life and they should have their own dignity and the sense of safety.Home-based community care for the old means a social service which takes the family as the core with community service network, and with pension system to guarantee [3]. It`s also a social service which the main content is solving the Old’s difficulties in daily life. Compared with the institutional care, the home-based community care has many advantages such as low cost, wide coverage, flexible service and so forth. It can also offer the service to the old with less cost. The more important, it can even take care of the old who lack of money but in need of care. So we can use the home-based community care to support the solid family and stable society [4].

Although the Home-Based Community Care of the Old has developed rapidly in recent years. And there are more and more pilot projects in local which are used for searching the innovation mode. But the system was just stared at present said many scholars [5]. The home-based care services in these areas are lack of a platform which is complete, operable and visible. As a result, this bad condition may lead to a tedious process or even missing some services when the old seeking for help. Therefore, the purpose of this topic is using the technology of jQuery Mobile (JQM) to construct an intelligent platform for many pension communities to use which aims to make the care service more convenient and effective.

Correlation Technique

1) jQuery Mobile

JQM is an open source JavaScript library framework and a mobile version of jQuery. The programmer can develop mobile website which runs across mainstream mobile platforms as well as

major mobile browsers with less cost. JMQ has been paid close attention by the mobile technology developers since 2010, when the JMQ was invented [6]. It's because that JMQ has the features such as: First, it`s easy to learn, which means we can develop a pleasing-looking mobile web programs swiftly by grasping some basic contents like pages and dialogue; Secondly, it's outstanding compatibility which means we can uniform the unified user's UI in the different diligent mobile phones and computers' web browsers which can help us to use some of the basic content like JQM box, the toolbar, button, content formatting, form elements, lists, APT and so on; Thirdly, it`s small scale, which means it contains only tens KB except icons after decompression; Fourth, it can support diverse input methods, including touch screens, mouse and the cursor on user inputs focus; Last but not least, we have custom theme, which means we can delimit various kinds of theme pattern easily by using the Theme Roller applications.

2) MySQL

MySQL is an open source of relational database management system (RDBMS). The MySQL database system manages the database by using the most common data management language--structured query system (SQL) [7]. The main features of the MySQL are small scale, quick running and open resource. Therefore, it's the first choice for many companies which have small or medium scale. At the same time, MySQL always comes out with Navigate which is a graphical management tool , so even a novice can do some basically operations on database management, which can greatly reduce the cost of database management.

3) Socket Communication

Socket is also called "socket", which is the API of TCP/IP, establishing a really stable and safe point-to-point communication. At present, most of the network use the Socket for interposes network communication. Socket appoints the specific IP and definite port for communication, and it would generate a Socket instance on each end of the application once connected correctly [8]. There are two types of Socket, connect-oriented flow socket and connectionless datagram socket.

4) JSON

JSON, a lightweight data-interchange format, which is easy for reading and writing, and computers can also digest and generate easily [9]. It can be used to write very practical, beautiful and readable code. The writing form of JOSN is name/value. The data format of JSON is very simple. It can transfer an easy String, Number, Boolean and an array, or even a complicated Object.

Function Partitioning

1) Requirements division

The need of the old people can divide into six parts: Economic Requirements, Consumption Requirements, Medical Requirements, Mental Requirements, Amusement Requirements and Social Activity Requirements. Among them, mental requirement on caring aging people is closely related to the quality of life and the happiness index which is significance for family stability and social harmony [10]. At recent stage, the coverage of the home-based community care services is still relatively narrow. The old people should be considered by not only the government but also the communities and families. And we should continue expending the content of service and guide the elderly to participate in social development so as to help them to realize their self-value.

2) Service Programming Established

According to the elderly questionnaire and a great deal of information from the Internet, we made 18 service items for old people which can be altered, added or subtracted in the future.

Theses 18 items are as follows: Key for Help; Family Hotline; Community Concur; Community Shopping, Community Service, Daily Reminders, Nutritious Meals, Medical Health, asking medicine, Health Topic, Brain Games, Weather Conditions, Traffic Conditions, connection to everything, Elderly University, Deposit and Investment, and Furniture Control. The medical health is a distinctive item which combine of remote medical technology comes from Italy ADiTech Company. And the ADiTech said they are willing to have a long-term cooperation with China in the construction of community home endowment.

Design of Software Platform

Based on the multi content of service, communities need a visual sense of software platform which can set out the content of services clearly.

1) Framework of Software System

The system architecture can be divided into four layers: Presentation Layer, Network Layer, Business Logic Layer and Data Layer，as shown in figure 1. In order to separate the function module and display module，the system use MVC as its design pattern, which can improve the system in maintainability, scalability, portability and reusability. The Presentation Layer just like the View in MVC, users uses the handset 'Browser' to surf different types of Webpage. HTML document prepared for static Webpage. ASP, JSP, PHP are Dynamic Webpage Languages which can be embedded into HTML. Next the Interpreter will interpret these words and return the result to the Browser; XML is a kind of data source like the File Database. Signals can be transferred through wireless network or wired network between users and the server. The network can be a LAN or WAN.But LAN will be the preferred for most users within the community. Business Logic Layer is similar to the Model in MVC. It used to handle the data of logic in applications, and its main task is to manage the equipment, network configuration, and business processing and user information. The resource of data used in Business Logic Layer is from Data Layer. The data is called by MySQL through WebService. And MySQL is managed by Navicat which is graphical software.

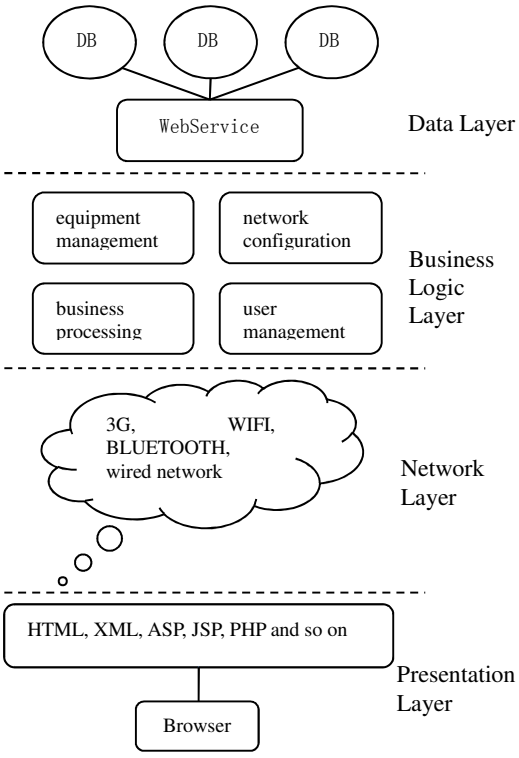

Fig.1. System architecture diagram

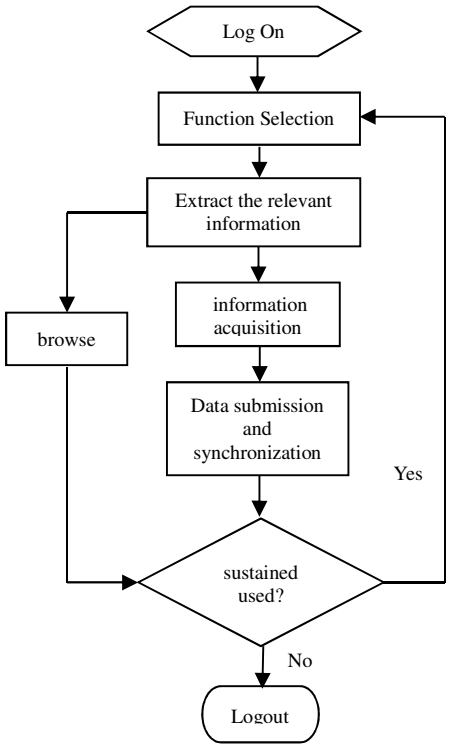

Fig.2. Flow chart of software operation

2) Scheme of Software Design

This topic uses NetBeans IDE 7.3 as the development environment. NetBeans is a tool for software developed which open its source code. It is a development framework which can be extended, also used for the development of program in Java, C / C++, PHP, HTML5 [11]. You must install JDK before installing NetBeans, and configure the system environment variables. For our topic is a design of a web site, so what we need is to use the web function of the application program in the NetBeans. And we should choose the default GlassFish Server as the web server. We create a web which should contain three files: jQuery JS, jQuery Mobile JS, jQuery Mobile CSS because we apply JQM framework since the initial interface. In addition, another important work is to establish a database which has a clear hierarchy layout through MySQL. Database will give all aspects of data resources like transportation, culture and life which are provide for the old. It need

to be updated in time and also includes the old own information. Such as name, phone number, ordering, part-time appointments, health indicators and treatment records. The old submit service orders to the background, as well as the background feedbacks the information confirms are both based on the Socket communication. In order to improve efficiency, we use Socket which is for connectionless datagram, and JSON structure.is used in data formats.

3) Flow Char of Software Operation

Figure 2 presents the software the chart of operation flow. The first step for the old to use the platform is to log in and the system will automatically turn in their relevant information. Then they can enter the main interface. The main interface is composed of 18 sub modules. If someone only wants to browse information, the system will display the corresponding data from the backstage database. When someone need to submit the order, shopping request or upload the measure data of health indicator (some of the relevant instrument can submit the data automatically), he/she should submit information so that the system can synchronize the database after receive the data. If the operation is completed, he/she can log off or continue to use other functions.

4) Function Module

Figure 3 and Figure 4 listed 2 modules from the 18 modules in the platform of home-based community care for the old. The topic use JQM plugins to reduce the complexity of program. Such as the Photo Gallery plugin Photos wipe which makes the picture and the operation more bright and colorful based on HTML, CSS, and JavaScript. It can be seen that even the illiterate old man can find the related services through these images.

Fig.3. Module of Elderly University

Fig.4. Module of Transport Guide

5) Software Equipment

In order to improve the service efficiency, the topic has some supporting software. Android application software is equipped for service personnel to use. There are different services with different icons, including ordering a meal, shopping, property, family therapy. Modeled on the QQ and chat in the upper right corner of which icon there will be pop-up unfinished message number. And it will renew timely after the staff deal with the event. In addition, in order to improve the compatibility and transmission efficiency supply video, we need to covert the format of the original video. So we use java to develop software of video format conversion. Its ‘features are different from those existing software. It can batch convert video formats, conversion result will level with the original folder hierarchy in corresponding. Each video file will be saved in a folder which using the same name with the video at the bottom. The folder will contain the new video format and three random screenshot. Select open-source ffmpeg as video compression solution. It supports many video compression standards including MPEG series and dozens of common AV file formats [12]. And it has high portability and codec quality. If we master the command set of ffmpeg we can get the specific quality and format.

Conclusion

The test shows that the software platform of home-based community care for the old based on JQM is a new type of pension platform which has social resources, can be clear operated and support multi benefits. Through this platform of elderly service can improve the quality of the old. What`s more it has positive significances because it can promote the reemployment of laid-off workers, perfect minimum subsistence guarantee system and promote the community integration. The platform is highly scalable and it can used in hospitals, trains and some other occasions in the future. So we need continual exploration and improvement to achieve a higher value with low cost.

Design and Implementation of Personalization Recommendation System in Mobile E-Commerce

Jinfeng MIAO

Xingtai polytechnic college, Xingtai, 054035,China

email: mjf0901@126.com

Keywords: Mobile E-Commerce; Personalized Recommender Systems; Design

Abstract. The purpose of this paper is to basing on the design of the mobile e-commerce personalized recommender systems, presents a method of personalized recommendation product information, and makes every effort to provide effective personalized service solutions for mobile e-commerce sites.

Introduction

Recent years, with the rapid development of the Internet technology, information technology and mobile communication technology, mobile e-commerce has become the new direction of the electronic commerce development. According to the requirement of the mobile e-commerce on personalized recommendation system, and combining content filtering technology with collaborative filtering technology, the author puts forward a weighted combination filtering recommendation system in this article.

1 The composition of the mobile e-commerce personalized services recommendation system

According to the working process of the personalized recommendation system in mobile e-commerce, the whole system is mainly made up of input function module, the function module of recommendation method and output function module.

1.1 Input function module

Its role is to collect information customer's personal and community groups. Customer's personal inputs, that is, target users Input evaluation project including the customer's personal attributes, purchase history, page browsing history, explicit browse input, keywords, and the project properties, etc. This information can help mobile business enterprise analysis of target customers' preferences, and then enterprises can recommend a suitable for their goods. Community inputs, namely the collective form of evaluation data, which includes the project properties, corporate purchase history, text evaluation and grade, etc. The information is the basis of social collaborative recommendation.

1.2 The function module of recommendation method

It is the core part of the recommendation system, and determines the performance of recommendation system. The main task of this module is to establish customer behavior model, analyze customer behavior characteristics or preferences, and then according to the results of certain recommendations have recommended.

1.3 The output function module

It is the content from the recommendation system to the user after the system input information. The main forms of module:

(1) Suggestion, Divided into single Item, unsorted suggestion List and ordered List. A typical such as Top-N, Namely according to customer's preferences, then the system recommends the most likely to attract customers' N pieces of goods to the customer.

(2) Prediction, Including: system overall score for a given project, the individual rating of goods from other customers， review about the goods from the customers.

2 Recommended technology and ideas about mobile e-commerce personalized service system

2.1 Recommendation technology

2.1.1 Filtering technology based on content

In the recommendation system, the objects of interest to the user are defined by feature. The method is based on the content and no memory; it can only recommend the related content to the customer based on the features of user previously seen or evaluation, etc.

2.1.2 Collaborative filtering technology

It recommends contend to the user based on the same interests or program. The basic starting point of induction:

(1) According to the classification of preference;

(2) If the user rating of some projects is similar, they also similar to the evaluation of certain projects.

2.2 Ideas about personalized services recommendation system

This article analyzes user forecasts by content filtering and collaborative filtering technology, and then uses the weighted sum method. First of all, according to the mobile users purchase history log data and browsing behavior, to extract the characteristics of potential information and then form a user interest model. Second, given the similar interest, the similarity about characteristics of the same goods evaluation from the users, the users are divided into category. Finally, to combine the weighted sum of contribution to the recommended, so as to form the final recommendation results.

3 The basic framework and process of personalized recommendation system

3.1 The basic framework of personalized recommendation system

As shown in Fig.1, after the user login page, the system will analysis, recommend the results to the user by information collection.

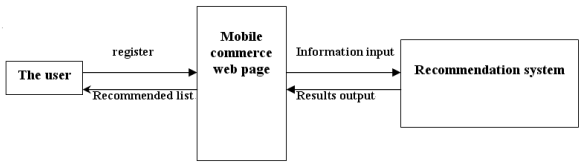

Fig.1. The basic framework of personalized recommendation system

3.2 The process of personalized recommendation system

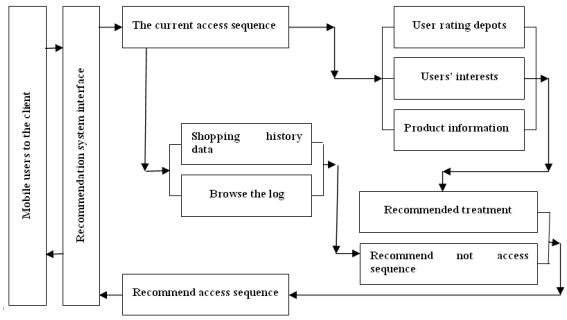

Fig.2. Personalized recommendation system process

As shown in Fig.2, the basic process of recommendation system is: First, the content, such as the customer shopping history data, the current access sequence and browse the log, are processed in advance. Second, through data processing, the system creates content filtering recommendation module; Finally, two recommendation modules are weighted summation, and related products in the product information database are generate a variety of recommended access sequence, which are recommended by moving the personalized interface on the server to the user.

4 Algorithm design about the personalized recommendation system

4.1 Algorithm design about content filtering recommendation module

In this module, the user's current access sequence is converted to interest topic vector. Customer shopping history data and browsing log, which are formed the feature vector by weighting computation. Then they form the initial recommendation model vector. By calculating the degree of similarity between the current access sequence and the initial vectors, the system finally set initial similarity values for interest topic of everyone.

Assumption: I-the user's interest; Pf0(I)-the initial I recommend model vector about I;P0-interested topic vector about users; P1- feature vector from shopping history data of customer; P2-feature vector from browse the log of customer; wi- the Ith interest in vocabulary; X,Y,Z for the respective weight.

$$Pf_0(I) = \mathrm{X} \times P_0(I) + \mathrm{Y} \times P_1(I) + \mathrm{Z} \times P_2(I) \tag{1}$$

Based on the formula in the smart recommendation system，which was build by Buckley

$$\mathrm{P_{0i}} = \begin{cases} \log（\mathrm{N}/\mathrm{d}f（\mathrm{w_i}））,\text{if } \mathrm{w_i} \in \mathrm{I} \\ 0, \quad \text{otherwise} \end{cases} \tag{2}$$

$$\mathrm{P_{1i}} = \begin{cases} \mathrm{logMI}（\mathrm{w_i},\mathrm{rel(I)}）,\text{if logMI}（\mathrm{w_i},\mathrm{rel(I)}）\geqslant 3 \\ 0, \quad \text{otherwise} \end{cases} \tag{3}$$

$$\mathrm{P_{2i}} = \begin{cases} \mathrm{logMI}（\mathrm{w_i},\mathrm{pseudo\text{-}rel\ (I)}）,\text{if logMI}（\mathrm{w_i},\ \mathrm{pseudo\text{-}rel(I)}）\geqslant 3 \\ 0, \quad \text{otherwise} \end{cases} \tag{4}$$

In the recommendation system, the threshold is adjustable.

4.2 Algorithm design about collaborative filtering recommendation module

According to user's interest in similarity, the interest is classed as a kind of similar users, thus gain n content clustering(C_1,C_2,C_3,……,C_n).

Ci=(Ui1,Ui2,Ui3,……,Uili),li-The number of users

A user feature vector:Uij=(tij1, tij2, tij3, ……,tijk),j=1,2,3,……,li

Category feature vector:

$$C_i = \frac{1}{l_1}\left\{ \sum_{j=1}^{l_1} t^{ij}{}_1, \sum_{j=1}^{l_i} t^{ij}{}_2, \ldots \sum_{j=1}^{l_i} \mathrm{t}^{ij}{}_k \right\} \tag{5}$$

The similarity of feature vectors between the text information and the clustering content.

$$\mathrm{sim}_{CE}(U,T) = \mathrm{sim}_{CE}(C,T) = \cos(C,T) = \frac{\sum_{\mathrm{j=1}}^{\mathrm{ili}} C_{\mathrm{j}} \times \mathrm{T_j}}{\sqrt{\left(\sum_{\mathrm{j=1}}^{\mathrm{ili}} C_{\mathrm{j}}^2\right)\left(\sum_{\mathrm{j=1}}^{\mathrm{ili}} T_{\mathrm{j}}^2\right)}} \tag{6}$$

The division of collaboration clustering can consult content clustering. The average of interest strength is regarded as intensity of interest from text in cooperation clustering.

4.3 The results from the weighted combination recommend

$\mathrm{sim}_U(\mathrm{U},\mathrm{T})$ -the similarity between Text feature vector and the user vector

$\mathrm{sim}_{CE}(\mathrm{U},\mathrm{T})$ -the similarity

$G_{DE}(\mathrm{U},\mathrm{T})$ -the similarity about user content clustering between Text feature vector and the user vector

$\mathrm{S}(\mathrm{U},\mathrm{T})$ -the relevance of user and the text

$$\mathrm{sim}_U(\mathrm{U},\mathrm{T}) = sim_U(\mathrm{pf},\mathrm{T}) = \cos(\mathrm{pf},\mathrm{T}) \tag{7}$$

$$\mathrm{sim}_{CE}(\mathrm{U},\mathrm{T}) = sim_{CE}(\mathrm{pf},\mathrm{T}) = \cos(\mathrm{C},\mathrm{T}) \tag{8}$$

$$G_{DE}(\mathrm{U},\mathrm{T}) = \frac{1}{MN_U}\sum_{i=1}^{MN_U} g(T,B_i,\mathrm{U}_i) \tag{9}$$

$$S(U,T) = \alpha\times\mathrm{sim}_U(U,T) + \beta\times\mathrm{sim}_{CE}(U,T) + \gamma\times\mathrm{G}_{DE}(U,T) \tag{10}$$

α,$\beta$and γ is for the adjustable weight parameters.

5 The recommended method of personalized recommendation system

This system can realize the four kinds of personalized recommendation method.

(1) Recommend in response to user requests.

This is the most basic of personalized recommendation service. As long as the system thinks that is associated with user interest, is to form a recommended sequence to the user, and then the users determine whether is effective. Its characteristic the similarity is whether is greater than or equal to the threshold.

(2) The most popular recommendation.

According to all the user's preferences, the system shows the most popular, the same product category. This recommendation does not consider the current user’s interest preference, but determined by the degree of sales.

(3) The latest recommendation.

This recommendation does not consider the current user interest preference. As long as within the scope of a certain amount of time, the system recommends these commodities to the customer.

(4) The user personalization recommendation.

According to corresponding user customization service, system will recommend the customize product information to the users. In the accurate identification of the user's identity and customization service type, according to the different customize service, the system can do different recommendation to users in response.

Keywords: PCA; Feature Selection; Maxima-order; Network Traffic

Abstract. In network traffic classification, by conventional PCA method, more features still exist due to uniform contribution rates for most of features. To overcome this problem, in this paper, a novel feature selection method is proposed to reduce data dimension of network traffic. A contribution rate of various features in each component is calculated by a new weight criterion. A maxima-order principle is proposed to determine feature selection. Based on three multi-class classification methods, performance comparison is conducted by actual traffic data with 10-fold cross-validation. Experiment shows that the proposed method has higher classification accuracy than conventional PCA method.

Introduction

Network traffic monitoring is an important way to keep network security and management [1]. Network traffic classification is a key for network traffic monitoring [2]. According to traffic classification, we can identify various applications, monitor and control the whole network, optimize network performance and improve the quality of service while keeping the network security. Network traffic contains many attribute features, e.g. the standard Moore set [3] selects the TCP flows with complete semantics (start with 3 TCP handshakes, end with 3 TCP handshakes) as network traffic samples, each sample contains 248 attribute features. Obviously the number of attribute feature is too big to be use, and it leads to heavy computation. At the same time, the redundant and related features may be included. So it is very important to reduce the attribute dimensions.

Feature selection is vital to reduce attribute dimensions. Literature [4] proposed a feature selection method by integrating filter and wrapper models. [5] used two filter-based feature selection methods for classification algorithms. [6] proposed a lightweight for intrusion detection system based on filter mode and feature selection.[7] proposed a set of features for P2P internet traffic detection and classification using Support Vector Machine by analyzing different types of features. [8] used fast correlation based filter (FCBF) for feature reduction and naive bayes algorithm to assess the reduction effect. [9] applied two optimal features subsets to provide better result in term of accuracy. [10] used random search algorithm for features reduction to identify P2P traffic by using SVM.

The principle of PCA is to convert the original data into a new coordinate system through linear transforming [11]. Literature [12] proposed a method to select informative object features using a sparse PCA. Network traffic has so many features that conventional PCA still provide more features due to uniform contribution rates for most features.

To overcome this problem, in this paper, a novel feature selection method is proposed. Firstly, according to contribution rate of principal component, the key principal components are chosen. A contribution rate of various features in each component is calculated by a new weight criterion. Secondly, a maxima-order principle is proposed to determine feature selection. Experiments show that our proposed method can greatly reduce feature dimension and obtain better recognition results.

A Novel Feature Selection Method based on Modified PCA

We assume the sample set is X, i.e. the feature set of network traffic can be denoted by $X^{n\times p}$ where n is the number of samples and p is feature number of network traffic. First, to keep uniform of network traffic data, we normalize X as follows:

$$x_{ij}^{*}=\frac{x_{ij}-\bar{x}_j}{\sqrt{\mathrm{var}(x_j)}} \qquad (i=1,2,\cdots,n; \quad j=1,2,\cdots,p) \tag{1}$$

Where $\bar{x}_j$ is mean value of jth column of X and can be expressed by

$$\bar{x}_j=\frac{1}{n}\sum_{i=1}^{n}x_{ij} \tag{2}$$

$\mathrm{var}(\cdot)$ is variance of X and can be depicted as

$$\mathrm{var}(x_j)=\frac{1}{n-1}\sum_{i=1}^{n}(x_{ij}-\bar{x}_j)^2 \qquad (j=1,2,\cdots,p) \tag{3}$$

And then we get the correlation coefficient matrix R. We assume the normalized data is still represented by X, so the correlation coefficient of X is presented as follows:

$$r_{ij}=\frac{1}{n-1}\sum_{t=1}^{n}x_{ti}x_{tj} \qquad (i,j=1,2,\cdots,p) \tag{4}$$

Through the Jacobi method, we can get the eigenvalues ($\lambda_1,\lambda_2\cdots\lambda_p$) and the corresponding eigenvectors $a_i=(a_{i1},a_{i2},\cdots a_{ip}),i=1,2\cdots p$ of the correlation coefficient matrix R, and then obtain p principle components. All these p principle components are obtained in descending order, so the amount of information they contained are obtained in descending order too. The variance of a principal component accounts for the proportion of total variance (i.e. the corresponding eigenvalue account for the proportion of total eigenvalues) is called the contribution rate; bigger contribution rate means that the principal component contains more original information and is shown as:

$$\mathrm{k}r=\frac{\lambda_i}{\sum_{i=1}^{p}\lambda_i} \tag{5}$$

The sum of contribution rate for the first k principal components is called cumulative contribution rate and is expressed as $cumcontri$, the selection of k depends on the actual needs, and generally the cumulative contribution rate should be more than 85%.

We assume the sample set is $X=[x_1,x_2,...,x_p]$, its eigenvectors matrix which satisfies the contribution rate is $U=[u_1,u_2,...,u_k],k<<p$; its principle component can be expressed as follows:

$$Y=U^TX=\sum_{i=1}^{k}u_ix_i \tag{6}$$

The purpose of network traffic feature selection is to select the main features from X which can represent the principal component. So how to choose the main features from matrix U is very important. Here we propose a criterion based on feature contribution rate on principle components.

We define the eigenvectors $u_i=[u_{i1},u_{i2},...,u_{ip}]$, and get the contribution rate of u_i and can be expressed by

$$cr=\frac{u_i}{\sum_{j=1}^{p}u_{ij}} \tag{7}$$

Arrange the above cr in descending order and then get u_i which satisfies the accumulative contribution rate $cumcontri$ between 85% and 95%, the first i components of u_i is the feature selection result of X. We express the feature label set as $index$ and it can be depicted by

$$index = \{i, 1 \le i << p, cumcontri = \sum_{k=1}^{L} contri_k \ge T\} \quad (8)$$

But the amount of components that satisfies the $cumcontri$ is often too much, the features are still too many, i.e. the dimension reduction is not satisfactory. In order to reduce the dimension further, our approach is to search the components in u_i which has the maximum magnitude and can be depicted as:

$$u_i^* = \left\{u_{ij}^*, \max(\lfloor u_i * 10^m \rfloor) \le 10, m = 1,2,...\right\} \quad (9)$$

Then select the corresponding feature label set from X, and expressed as ind

$$ind = \left\{i, 1 \le i << p, u_i == u_i^2\right\} \quad (10)$$

According to formula (9) and (10), we can get the feature selection of network traffic, expressed as X^{Sel}

$$X^{Sel} = X(ind) \quad (11)$$

Through the above process, we effectively reduce attributes of network traffic, and achieve the purpose of dimension reduction and features selection.

Algorithm Description of Proposed Feature Selection Method

We briefly describe the proposed algorithm as follows:

1) Normalize the network traffic data according to formula (1);
2) Calculate the correlation coefficient according to formula (4);
3) Build corresponding eigenvector matrix through formula (5) and (6);
4) According to formula (7) and (8), get the feature label set of eigenvector columns;
5) Obtain the minimum feature set from formula (9) and (10);
6) Get the result of feature selection from formula (11).

Experimental Results

We conduct experiments to test the feasibility of the proposed method with 10-fold cross-validation. Three classification methods are used to conduct comparisons between proposed method and conventional PCA method. They are One-Against-One (OAO) [13], One-Against-All (OAA) approach [14], Binary Multi-class classifier [15]. Experiment data is selected randomly from the Moore set used in [3]; there are totally 10280 samples be selected and each sample includes 248 features. The experiment data is divided into 10 equal parts; we choose one part in turn as testing set and the rest 9 parts as training set, and conduct classification. Then repeat the above experiment 10 times; the average classification accuracy of each method is recorded in table 1. Using our proposed method, the number of selected features is 25. Comparison result shows that the proposed method increases the classification accuracy in contrast with conventional PCA method.

Table 1 Average classification accuracy with each method

	OAO	OAA	Binary Multi-class
Conventional PCA	85.50%	88.51%	91.17%
Modified PCA	89.33%	91.01%	93.17%

Conclusion

In this paper, a novel feature selection method based on PCA is proposed. A contribution rate of various features in each principal component is calculated by a new weight criterion. A maxima-order principle is proposed to determine feature selection. Experiments show that our proposed method can reduce feature dimension and obtain better classification accuracy.

A Security Compliance Based Mobile User Authentication Scheme

Yifei Yuan [1, a], Lianzhong Liu [1, b], Chunyan Han[1, c]

[1] Beijing Key Laboratory of Network Technology of Computer Science and Engineering, Beihang University, Beijing, 100191, China

[a]email: ifay.yuan@gmail.com, [b]email: lz_liu@buaa.edu.cn, [c]email: hanchunyanbupt@gmail.com

Keywords: BYOD; compliance strategy; authentication

Abstract. The BYOD (Bring Your Own Device) scenario puts traditional two-factor authentication into great security challenge. To strengthen the authentication in BYOD scenario, we propose a security compliance based mobile user authentication scheme, which includes a novel calculation method for device identifier, and a fine-grained compliance strategy and its management. The scheme provides a secure authentication mechanism for BYOD scenario and satisfies the requirements of device authentication in mobile user authentication.

Introduction

With the fully developed techniques of intelligent devices and its widespread, personal intelligent devices represented by mobile phones and tablets has come to enterprise area, which is called as BYOD mode. The diversity of employees' devices makes it difficult to manage and authenticate mobile devices. Thus how to protect enterprises' sensitive data from illegal access has become an important issue [1, 2].

Traditional two-factor authentication (2FA) scheme has two main drawbacks [3]. First, it can only authenticate the users, but can do nothing about the devices, so employees are able to use unregistered devices to access business data, which may cause data leakage. Second, it cannot control the security of employees' devices, that is, an unsecure device may be allowed to get access to the sensitive business data and the uncertain functions and applications on the device may get the corporate data illegally [4]. In this paper, we improve the traditional 2FA, and propose security compliance based mobile user authentication scheme.

Background and Related Research

There are three authentication factors that are typically used to authenticate users: proof-of-knowledge, proof-of-possession, and proof-of-characteristics [2].

Much work around authentication factors and their security has been done. As to the proof-of-knowledge factor, traditional user-defined password is either easy to guess or subject to brute force attacks. In mobile times, researchers start investing the use of OTP (One Time Password) technology [5].

The proof-of-possession factor is most frequently strengthened in banking systems and e-commerce systems, which requires strict security. Jhe-Yi used a three-factor authentication combines PIN code authentication, USIM (Universal Subscriber Identity Module) card authentication and facial biometric authentication [6]. However, the USIM card only exists in UMTS (Universal Mobile Telecommunications System) phones and cannot be a universal identifier for BYOD scenario.

Paper [7] focused on strengthening the "something you are" factor and proposed a multi-factor authentication method combined facial, voice and iconographic biometric factors to strengthen the mobile authentication. Three bio-factors may be secure enough for enterprise usage, but its high precision will also lead to a low recall rate, which will cause inconvenience in practice.

Besides the three factors mentioned before, there are additional authentication factors like location and time added to authentication systems. Paper [8] proposed a location-assured,

multi-factor authentication on smartphones via LTE communication. To guarantee the security and reliability of location information, they use both device-collected location and LTE-provided location.

The previous research work mostly focused on the strengthening of authentication factors, which is not enough for BYOD scenario. The BYOD scenario stresses the importance of authentication of both user and device, and requires more on additional authentication factors such as location and application-state on device. So we propose a security compliance strategy to limit the additional authentication factors and use a novel calculation method for device identifier to adjust the diversity of devices.

Authentication Scheme Overview

In this section we will discuss the factors needed in our authentication scheme, and give a formalize description of mobile user authentication. We use a two-tuple $< \text{FACTORS}, \text{RULES} >$ as authentication vector. The explanation of each item is described as below:

FACTORS : the authentication factor set, $\text{FACTORS} = \{\text{DEID}, \text{PWD}, \text{OPTION}\}$, in which DEID denotes the device's unique identifier, PWD represents the password set by users and OPTION means a configurable option set for enterprises to adjust to their own security requirements.

$\text{OPTION} = \{\text{TEL}, \text{JMUN}, \text{BIO}, \text{TOKEN}\}$, the elements in set refer to employee's telephone number, job number, biological features and hardware token respectively. All the elements except for $DEID$ are configurable[9], that enterprise can define their own method to generate PWD, such as OTP (one time password) or SMS-based password, and decide whether to use more factors to strengthen the authentication scheme according to their security requirements.

As to $DEID$, researchers have proposed different methods to select the most suitable one. Steven Furnell disscussed the feasibility of using PIN code to authenticate and suggested that flexible, multi-level authentication of the user [10]. Before we decide which to choose as $DEID$, lets first check and discuss different devices' identifiers adopted by vendors.

Table. I Identifiers of mobile devices

Identifier	Meaning	Usage	Storage Location	Length
IMSI	International Mobile Subscriber Identification Number	Identifier for mobile device subscriber	SIM card	15-digit
IMEI	International Mobile Equipment Identification Number	Identifier for mobile device	GSM&WCDMA network device	15-digit
ESN	Electronic Serial Numbers	Identifier for mobile device	CDMA network device	8-digit
MEID	Mobile Equipment ID	Strengthened ESN	CDMA network device	15-digit
MAC address	Media Access Control	Network device identifier	NIC	48bit

From table 1 we can see that different devices use different identifiers. For the devices with SIM card, such as mobile phones, IMSI may be used as $DEID$ if we ignore the fact that CDMA devices' IMSI cannot get through program. But for devices without SIM card, such as tablets and mobile phones without SIM card, we may use IMEI or MEID or ESN as $DEID$. The length of identifiers mentioned in above table are also different to each other, thus the $DEID$ cannot be unified, so we proposed a novel calculate method for $DEID$, which will be described in II.A section.

RULES: the compliance strategy set, defined as:

$$RULES = \{rul_1, rul_2, \ldots, rul_n\} \quad (1)$$

The RULES is compliance strategies set by enterprise administrator, aiming at checking devices' security state and users' state. Thus the RULES includes two main parts: the compliance strategy for devices and the compliance strategy for users, and each rule is composed of compliance items and logical operators. Table. II describes the items in compliance strategy.

Table. II Description of compliance strategy items

category	compliance item	description
device	dOwnership	device ownership type: employee-owned, corporate-owned or shared device
	dVersion	device's platform and version
	dState	device state: whether has got the super user permission
	dType	device type: mobile phone or tablets
	dFunction	device function, includes WiFi, 2/3/4G, camera, Bluetooth, GPS etc.
	dLocation	device's location
	dWLApp	whether device includes all of White List Apps
	dBLApp	whether device includes none of Black List Apps
	dMax	max number of simultaneously online device
user	uPwdLength	user password length
	uPwdStrength	user password strength
	uPwdValid	whether user password is in valid period
	uAttempt	the login attempt times
	uValid	user account validity

Here is an example of compliance strategy:

$$RULE1 = (dOwnership = employee\ owned)\ AND\ (dVersion > Android4.0)\ AND\ (dState = NotRoot)\ AND\ (dType = phone)\ AND\ (dFunction = wifi\&GPS) AND\ \big(dLocation = (116.00E, 40.90N)\big) AND\ (dWLApp = true) AND\ (dBLApp = true)\ AND\ (dMax \leq 3) AND\ (uPwdLength \in [10,16]) AND\ (uPwdStrength = Char\&Num) AND\ (uAttempt < 4) AND\ (uPwdValid = valid)$$

The RULE1 means when authenticate user devices, the compliance strategy requires that device is employee owned phone, and the version of device platform is higher than Android 4.0, and is not rooted, and device's Wi-Fi and GPS functions are enabled, and device's location is at 116.0 east longitude and 40.9 north latitude, and ALL the white list apps have been installed on the device and none of the black list apps is installed, and no more than three devices can be online simultaneously. Also RULE1 requires user password length should between 10 and 16 characters and the password should include both characters and numbers, and total trial time should less than 4 times, and password is valid.

A. The calculation method for $DEID$

As one of the most important factors in 2FA scheme, $DEID$ is quite different between devices, and the length of device identifiers cannot be unified. Here we propose a SHA1-based calculation method for DEID, which is unique for device and is calculated from device hardware to guarantee that the $DEID$ will not change with reboot or factory reset.

$$DEID = SHA1\big(IMEI\,|MEID|\,ESN + MACAddress + BlueToothAddress\big) \quad (2)$$

The IMEI|MEID|ESN means the first calculate factor is IMEI(for GSM devices) or MEID|ESN (for CDMA devices), the second factor is MAC address of device's NIC, and the third factor means the device's Bluetooth address if exists. The $DEID$ will be of 160-bit length after the SHA1 algorithm.

B. The management of compliance strategy

Compliance strategy must be defined in the enrollment procedure. When a user registers into enterprise system, the enterprise administrators must allocate or define a proper compliance strategy for the user according to his or her role in the company. Each time the device connects the internet, it is automatic to check the local compliance strategy's integrity and update. The integrity check's object is the MD5 of local compliance strategy file, and if it differs from the MD5 of server's compliance strategy file, which may be caused by illegal operation from local device or the update of server's compliance strategy, then the local enterprise application will download and apply the

newest file from server. Also, when an employee's working role changes, his or her compliance strategy will also be changed by the enterprise administrator.

Design

The authentication procedure involves four entities: user, device client, authentication server and enterprise service. In BYOD scenario, users refer to employees, and device client include mobile device and the applications installed on it, especially the enterprise application.

Step 1: The employee request to access to enterprise service client (such as an app) on mobile device, and type in password to get through.

Step 2: After the employee passed the app's authentication, he (she) is authorized the permission to operate the enterprise client.

Step 3: The employee requests to access enterprise service through the client.

a)The client queries the server to check local compliance strategy's integrity and updates.

b) The enterprise server replies and client synchronizes local compliance strategy to server.

c)Then device client does self-check according to compliance strategy.

d) Then the device client sends employee's request to authentication server where employee's compliance will be checked.

Step 4: After all compliance strategies are meet, employee can commit business operations and communicates with enterprise service.

Fig.1 shows the sequence of mobile user authentication scheme.

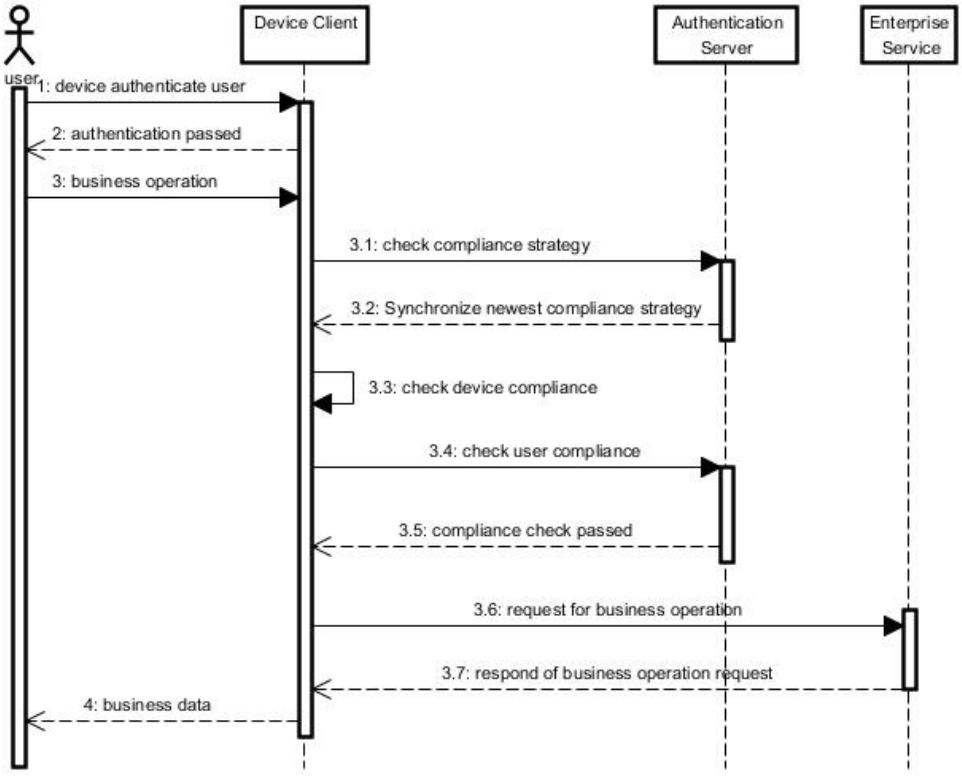

Fig. 1 Sequence diagram of the authentication procedure

The table below shows the algorithm in Step 3. The algorithm includes compliance-checking part and the logging part, which is an important part for enterprise to do auditing later.

Table. III Check Compliance Algorithm

Algorithm：CheckCompliance
Input： None
Output：Success|Fail, ResultList
Condition precedent:

```
1. Synchronize Local Compliance Strategy
2. Synchronize Black and White App List
Initialization:
ResList=null
Process：
For each item in ComplianceStrategy
    If ItemType(item)=Device
        itemVal=getItem(item)
         ResList.put(item,itemVal)
        If Compare(itemVal,item.restriction)=true
            Log(item,itemVal)
            Continue
        else
             LogError(item,itemVal)
    If ItemType(item)=User
        sendCheckRequest(item.val)
        result=getCheckResponse(item.val)
         ResList.put(item,result)
        If result=false
            LogError(item,itemVal)
        else
            Log(item,itemVal)
  Return List
```

Conclusion

In this paper, we focus on the drawbacks of traditional two-factor authentication scheme and make two main improvements to fulfill the requirements of mobile device authentication. First, we propose a calculation method of device's unique identifier to unify the authentication factor of device identifier. Secondly, we support a fine-grained compliance strategy for enterprises to strengthen the security of their authentication procedure.

Keywords: CA authentication; IPv6; security multicast; system

Abstract. To deploy network components of a security multicast which is based on the multicast group security architecture and its key management architecture, an IPv6 security multicast system using CA authentication is designed. The multicast group members use CA certificate to access network, while the role of Group Controller/key Server deployed in the network is to establish and manage the group key and negotiate SA with multicast source. The proposed scheme solves the problem of components deployment of multicast system with security, and has strong scalability as well which means various multicast protocols and group management protocols can run on this system.

Introduction

Multicast is an important supporting technology for the next generation Internet applications. The security problem hinders the widespread use of multicast technology. Secure multicast system includes multicast security architecture and group key management framework, and key management protocols and algorithms. Secure multicast architecture and usage of the GSA group key management protocol is proposed by the Internet Engineering Task Force (IETF) in RFC3740, RFC4046. However, combined with the existing multicast routing protocols such as Protocol Independent Multicast (PIM), group management protocols such as Internet group management protocol (IGMPv6) and Multicast Listener Discovery (MLDv2), and using a efficient group key management algorithm, the design of safety and ease of deployment of multicast system is still a challenge. Based on the comprehensive consideration of secure multicast architecture, multicast security key management architecture, protocol and algorithm, a security multicast system is presented in this paper.

The hierarchical architecture Iolus[1] is suitable for dynamic multicast applications, but its decryption efficiency is low, and it is difficult to play a role in large dynamic multicast environment. The distributed architecture[2] can avoid single point of failure, but due to the adoption of policy based mechanism, it lacks of flexibility in a large and dynamic environment. A two layer of mobile multicast key management architecture and algorithm is proposed in reference [3]. According to the mobile environment, by the number of subgroup member is saturated or not to determine whether to generate a new subgroup. However, this method itself and the moving member dynamics are contradictory. The logical key tree includes the group key management algorithm of LKH, TOFT, CGKA are proposed in the reference [4-6], respectively. They all have their own advantages, and the requirement of secure multicast key management can be satisfied in a certain environment. But their common weaknesses that focuses on the algorithms themselves, rather than to consider how to deploy the device when the algorithm is implemented.

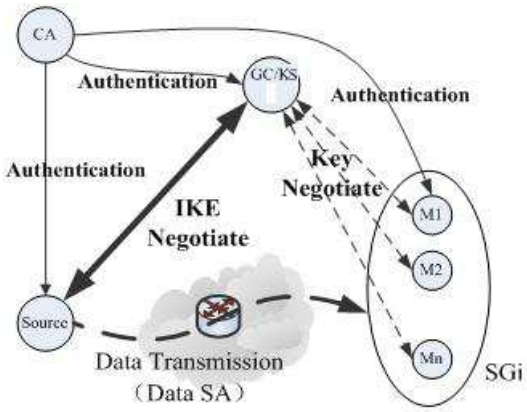
Therefore, we need to design an efficient key management system that can adapt to the application of large dynamic environment and a security multicast system that can be convenience to the implementation of variety group key management algorithm

This system is put forward in RFC3740 multicast security framework and RFC4046 definition of group key management framework. Multicast communication protocol mainly includes the routing protocol and group management. A typical multicast routing protocol is PIM[7] protocol with various models for different applications such as Dense Mode (DM), Sparse Mode (SM), and a

protocol for source specific multicast (SSM). The MLDv2 protocol sub protocol of IGMPv6 is used for group management protocol in IPv6. The system will run the above protocol to realize multicast communication.

Secure Multicast Architecture

As shown in Figure 1, the system mainly consists of 4 parts, which is CA center, multicast, group members and GCKS. The CA center authenticates multicast source, GCKS and group members. Multicast source is multicast data sender, which can be a member in the group that receives multicast data, also may be an outside group member. GCKS is the group controller and the policy server, which is responsible for the consultation of group management key generation with multicast source.



System Function Module and Deployment

As shown in Figure 2, the system consists of three parts divided from the function modules, which is multicast communication module, key management module, and authentication module. I is the IP multicast module, and the thick solid line represents the path of multicast data transmission. II represents a group key management part, main including the group key foundation, distribution, and group key management. Dotted lines refer to the possible key negotiation between GCKS, and a GCKS may correspond to multiple routers. III is authentication module, and the arrows indicate the authentication of the GCKS and group members by the CA center. In this system, CA authentication is a authentication mechanism to provide the required safety, and it is safe and credible.

Routers support multicast in the IPv6. Routers support and run the IGMPv6 and related protocols such as MLDv2. Therefore, the deployment of IP multicast module for general network deployment do not need to set up additional components. The core component of multicast key management is GCKS. The deployment of GCKS adopts distributed deployment mode, and the higher performance of the host or server is selected as the GCKS in a certain range. The authentication module bases on the current mature CA certification deployment method.

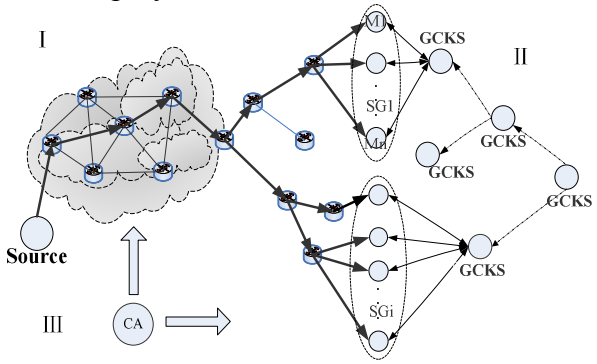


Fig.2 System function module

Multicast Communication Process

"Query and response" communication mode is adopted in the IP multicast communication. The foundation of a multicast group is an important process of multicast communication. Firstly, the query router is determined by election mechanism in the access router. The query router periodically sends query messages to the local link, and the host on the link decides whether to join multicast groups though its response to the query message. Then, the query router founds multicast listener query list according to the received response message, and Multicast data forwarding is decided by the router MLD list. Another important process of multicast communication is to determine the multicast routing, which is the process of multicast data transmission from the multicast source to the access router. For the multicast from single point to multipoint, a source specific multicast routing protocol such as PIM-SSM, has the high efficiency of the host to join a multicast group in PIM-SM mode, skips the shared tree and Rendezvous Point (RP) rules in PIM-SM mod, and uses the Channel to uniquely identify a group communication. Therefore, PIM-SSM routing protocol is adopted in the routing process of this system.

In secure multicast system, the protection of end-to-end data and the multicast distribution tree, and the access control of membership in subnet hierarchies need to be provided. IPSec is employed to provide the above safety requirement in this system, which is the frame of Group Security Association (GSA) proposed by RFC4046, including register SA, update key SA, and data SA. The register SA provides information a protection for GCKS registration from group members. Key update SA offers a protection of key update material for group members updating. Data SA protects the multicast data flow from the source to the group members. Due to the IPSec is a kind of point to point protocol designed for the unicast system, compatibility problems exist between the secure multicast protocol and the IPSec protocol suite, which performs mainly in the establishment of data SA in the GSA.

In this system, related parameters of GCKS and multicast source negotiation data SA are used, and GCKS implements group key generation and group key management. Firstly, GCKS consults with group members on the group key. Then, as the group agent GCKS negotiates with the multicast source on the data SA. The certification part of the system bases on CA authentication certificate mode.

The process of security multicast communication for this system is shown in figure 3. After the encrypted multicast data are obtained by the group members, the multicast data can be decrypted by group key obtained from the GCKS.

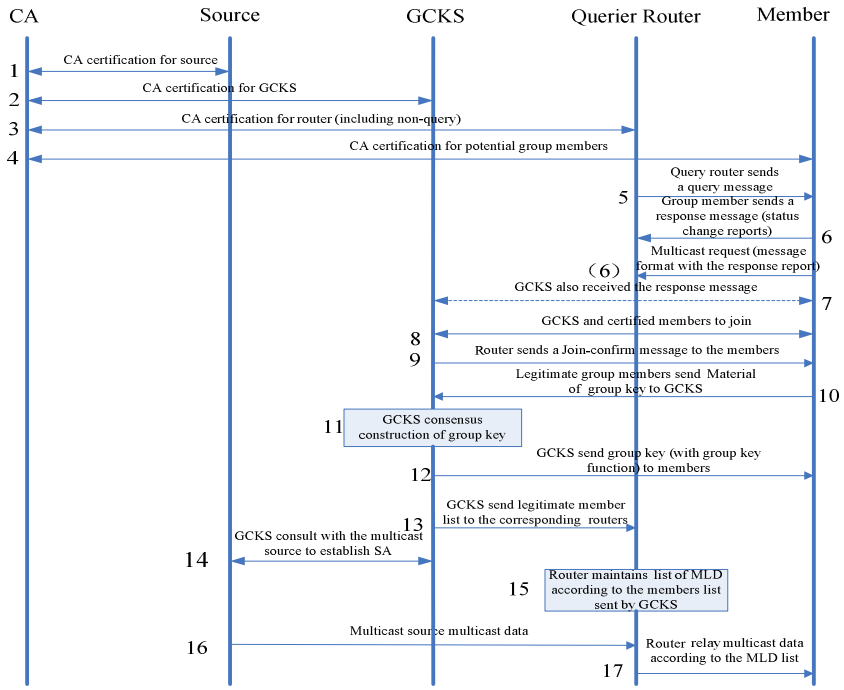

Fig3. Processing system

System Performance Analysis

The system provides a method for the secure multicast establishment and the equipment deployment. The security, deployment and other advantages of this system are shown below.

Security: the most important work in the system is that the data send from the multicast source is in protection by the data SA in GSA and it ensures the confidentiality of the data of the group members. Moreover, when members join multicast groups, it needs to use the certificate with GCKS mutual authentication, and the access control mechanism reduces the possibility of denial of service attacks (DoS) to a certain extent.

Deployment: multicast communication module and group key management module is relatively independent. In a secure multicast system, according to the required level of security requirements, appropriate GCKS level is set and connected to the network system, solving the function node entity deployment problem in the group key management algorithm. Meanwhile, this key management set independent to the multicast communication module is easy to use various group key agreement algorithms and has good scalability.

Efficiency: Compared to the security multicast management system proposed in patent [8], this system adopts the access authentication based on Certificate in real time through GCKS generating and distributing group key, and has a better dynamic. Moreover, this system considers the routing protocol and group management protocol of the current multicast, avoiding extra overhead.

Conclusion

The system can meet the safety requirement of multicast communication. Though the use of the certificate authentication mode, the problem of the use of SA in the multicast is solved, and the system has high security. Meanwhile, deployment of group key management is convenient and efficient, and has a good scalability. The equipment deployment is convenient to use the different key generation and management algorithm, getting good efficiency of the algorithm.

Research on SIQRS Spreading Dynamic Model with Feedback Mechanism on Scale-free Networks

Tao LI[a], Yuanmei WANG[b], Youping Yang[c]

School of Electronics and Information, Yangtze University, Jingzhou, 434023, China

[a]email: taohust2008@163.com, [b]email:yuanyzq@163.com, [c]email: youpingyang@126.com

Keywords: Model; Scale-free Networks; Feedback Mechanism; Threshold; Equilibrium

Abstract. A modified *SIQRS* spreading dynamic model with feedback-mechanism based on scale-free networks is presented in this study. Using the mean field theory, the spreading dynamics of the model is analyzed. The spreading threshold and equilibriums are derived. The relationship between the spreading threshold, the epidemic steady-state and the feedback-mechanism is analyzed in detail. Theoretical results indicate the feedback-mechanism can increase the spreading threshold, resulting in effectively controlling the epidemic spreading.

Introduction

The studies of complex network have attracted much interest since the seminal works on the scale-free property [1]. In the study of scale-free networks, a good example is to inspect the effect of the scale-free features on the epidemic spreading [2-9]. Using SIR and SIS models [6, 8], the absence of a spreading threshold has been observed. Currently, many of these results are based on the unchangeable topology structures of networks. For instance, a *SIQRS* epidemic model on scale-free networks without considering the change of topology structures [2]. In reality systems, people will decrease the contact with other people consciously while there is a disease spreading in crowd and the number of infections is growing. On the contrary, people will increase the contact with others people while the number of infections is going down [9]. That is to say, the structures of networks will be changed according to the feedback information. So the feedback mechanism is introduced in the study. The article is organized as follows. In Section 2, the establishment of scale-free network model is described. A modified *SIQRS* epidemic model with feedback mechanism on scale-free networks is proposed in Section 3. In Section 4, we conclude the paper.

The Network Model

In the paper, we focus on the Barab´asi and Albert (BA) model, which incorporates growth and preferential attachment. Starting with m_0 fully connected nodes, every time step a new node is added, with m edges that are connected to an old node with probability $\prod_{k_i}=k_i/\sum_j k_j$, where k_i is the connectivity of the ith node. After a long period of evolution, this network organizes itself into a scale-free stationary state, in which the probability that a node has k edges $P(k)=2m^2k^{-3}$, $k \geq m$, the mean number is $\langle k\rangle=\int_m^\infty kP(k)dk=2m$, the variance of node connectivity is $\langle k^2\rangle=+\infty$.

A Modified *SIQRS* Epidemic Model

In the proposed modified *SIQRS* epidemic model, the nodes can only exist in one of the four discrete states, namely, susceptible, infected, quarantined and removed, denoted respectively by S, I, Q, and R. Let $S_k(t)$, $I_k(t)$, $Q_k(t)$, $R_k(t)$ be the densities of nodes with degree k at time t. In the course of disease transmission, a susceptible node is vaccinated with probability α and infected with probability λ. Infective nodes are quarantined with probability σ or recover spontaneously with probability γ. Some useful management is employed on the quarantined nodes

so that they leave for the removed state with probability ε. Due to loss of immunization removed nodes join the susceptible nodes again with probability δ. For feedback mechanism we suppose the node disconnects his connection with the infected nodes with probability μ [9]. So the probability of the node disconnects with his neighbors is $\mu I(t)$. Based on the above hypotheses, using the mean field theory the dynamic mean-field equations can be written as

$$\begin{cases} \dfrac{dS_k(t)}{dt} = -\lambda k(1-\mu I_k(t))S_k(t)\theta(t) - \alpha S_k(t) + \delta R_k(t) \\ \dfrac{dI_k(t)}{dt} = \lambda k(1-\mu I_k(t))S_k(t)\theta(t) - \gamma I_k(t) - \sigma I_k(t) \\ \dfrac{dQ_k(t)}{dt} = \sigma I_k(t) - \varepsilon Q_k(t) \\ \dfrac{dR_k(t)}{dt} = \gamma I_k(t) + \varepsilon Q_k(t) + \alpha S_k(t) - \delta R_k(t) \end{cases} \tag{1}$$

The probability $\theta(t)$ describes a link pointing to an infected node, which satisfies the relation

$$\theta(t) = \frac{\sum_k kP(k)I_k(t)}{\sum_s sP(s)} = \frac{1}{\langle k\rangle}\sum_k kP(k)I_k(t) \tag{2}$$

Let $I(t)$ be the density of all infective nodes of the whole network at time t. Obviously, $I(t)=\sum_k P(k)I_k(t)$ is the density of infected nodes of the whole network. For $(1-\mu I_k(t))S_k(t) = (1-\mu I_k(t))(1-I_k(t)-R_k(t)) \approx S_k(t) - \mu I_k(t)$ the system (1) can be simplified as

$$\begin{cases} \dfrac{dS_k(t)}{dt} = -\lambda k(S_k(t)-\mu I_k(t))\theta(t) - \alpha S_k(t) + \delta R_k(t) \\ \dfrac{dI_k(t)}{dt} = \lambda k(S_k(t)-\mu I_k(t))\theta(t) - \gamma I_k(t) - \sigma I_k(t) \\ \dfrac{dQ_k(t)}{dt} = \sigma I_k(t) - \varepsilon Q_k(t) \\ \dfrac{dR_k(t)}{dt} = \gamma I_k(t) + \varepsilon Q_k(t) + \alpha S_k(t) - \delta R_k(t) \end{cases} \tag{3}$$

Theorem 1. There always exists a disease-free equilibrium $E_0(\delta/\delta+\alpha, 0, 0, \alpha/\delta+\alpha)$. Define $\rho = \dfrac{\delta\lambda}{(\alpha+\delta)(\gamma+\sigma+\mu)}\dfrac{\langle k^2\rangle}{\langle k\rangle}$. If $\rho > 1$, then system (3) has a unique endemic equilibrium $E_+(S_k^\infty, I_k^\infty, Q_k^\infty, R_k^\infty)$.

Proof. To get the equilibrium $E_+(S_k^\infty, I_k^\infty, Q_k^\infty, R_k^\infty)$, the equilibrium should satisfy

$$\begin{cases} -\lambda k(S_k^\infty - \mu I_k^\infty)\theta^\infty - \alpha S_k^\infty + \delta R_k^\infty = 0 \\ \lambda k(S_k^\infty - \mu I_k^\infty)\theta^\infty - \gamma I_k^\infty - \sigma I_k^\infty = 0 \\ \sigma I_k^\infty - \varepsilon Q_k^\infty = 0 \\ \gamma I_k^\infty + \varepsilon Q_k^\infty + \alpha S_k^\infty - \delta R_k^\infty = 0 \end{cases}$$

where $\theta^\infty = \dfrac{1}{\langle k\rangle}\sum_k kP(k)I_k^\infty$. One has

$$\begin{cases} S_k^\infty = \dfrac{\lambda\mu k\theta^\infty + \gamma + \sigma}{\lambda k\theta^\infty} I_k^\infty \\ Q_k^\infty = \dfrac{\sigma}{\varepsilon} I_k^\infty \\ R_k^\infty = \dfrac{(\lambda k\theta^\infty + \alpha)(\gamma+\sigma) + \alpha\lambda\mu k\theta^\infty}{\delta\lambda k\theta^\infty} I_k^\infty \end{cases} \tag{4}$$

According to the normalization condition $S_k^\infty + I_k^\infty + Q_k^\infty + R_k^\infty = 1$, we can obtain

$$I_k^\infty = \frac{\lambda k \delta \theta^\infty}{\lambda k \theta^\infty \left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right]+(\alpha+\delta)(\gamma+\sigma+\mu)} \tag{5}$$

Inserting (5) into (2), we can obtain the following equation

$$\theta^\infty = \frac{\sum_k kP(k)I_k^\infty}{\langle k\rangle} = \frac{\sum_k k^2 P(k)\dfrac{\lambda\delta\theta^\infty}{\lambda k\theta^\infty\left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right]+(\alpha+\delta)(\gamma+\sigma+\mu)}}{\langle k\rangle} \triangleq f(\theta^\infty) \tag{6}$$

Obviously, $\theta^\infty = 0$ is a solution of (6), i.e., $f(\theta^\infty) = 0$. We suppose that $f(\theta^\infty)$ is a continuously smooth function and then we can easily demonstrate that $f(\theta^\infty)$ is a strictly monotonic increasing function. To ensure (6) have a nontrivial solution the following condition must be satisfied, i.e., $\left.\dfrac{df(\theta^\infty)}{d\theta^\infty}\right|_{\theta^\infty=0} > 1$. So, we have

$$\left.\frac{d}{d\theta}\left(\frac{1}{\langle k\rangle}\sum_k k^2 P(k)\frac{\lambda\delta\theta^\infty}{\lambda k\theta^\infty\left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right]+(\alpha+\delta)(\gamma+\sigma+\mu)}\right)\right|_{\theta^\infty=0} \geq 1$$

Then, we obtain $\dfrac{\lambda\delta}{(\alpha+\delta)(\gamma+\sigma+\mu)}\dfrac{\langle k^2\rangle}{\langle k\rangle} > 1$. Let $\rho = \dfrac{\lambda\delta}{(\alpha+\delta)(\gamma+\sigma+\mu)}\dfrac{\langle k^2\rangle}{\langle k\rangle}$, a nontrivial solution exists if and only if $\rho > 1$. The epidemic threshold can be defined by

$$\lambda_c = (1+\frac{\alpha}{\delta})(\gamma+\sigma+\mu)\frac{\langle k\rangle}{\langle k^2\rangle} \tag{7}$$

Namely, the epidemic incidence will die out if $\lambda < \lambda_c$, and it will break out if $\lambda > \lambda_c$. Substitute the nontrivial solution of (6) into (5), we can get I_k^∞. By (4) and (5), we can easily get $0 < S_k^\infty < 1$, $0 < I_k^\infty < 1$, $0 < Q_k^\infty < 1$, $0 < R_k^\infty < 1$.

Therefore, the equilibrium $E_+(S_k^\infty, I_k^\infty, Q_k^\infty, R_k^\infty)$ is well-defined. Hence system (3) has a unique endemic equilibrium $E_+(S_k^\infty, I_k^\infty, Q_k^\infty, R_k^\infty)$ when $\rho > 1$. This completes the proof.

Now, consider the BA scale-free network model. As a matter of fact, the mean number of node degree and the degree distribution satisfy $\langle k\rangle = \int_m^\infty kP(k) = 2m, P(k) = \dfrac{2m^2}{k^3}$. Inserting this into (6), by integrating with respect to k the following can be obtained

$$\frac{1}{m} = \int_m^\infty \frac{\lambda\delta}{k\left\{\lambda k\theta^\infty\left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right]+(\alpha+\delta)(\gamma+\sigma+\mu)\right\}}dk$$

which yields

$$\theta^\infty = \frac{(\alpha+\delta)(\gamma+\sigma+\mu)}{m\lambda\left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right](e^{\frac{(\alpha+\delta)(\gamma+\sigma+\mu)}{m\lambda\delta}}-1)} \tag{8}$$

By (5) and (8), we get the density of infected nodes in the steady state of the whole network

$$I^\infty = \sum_k P(k)I_k^\infty = \frac{2\left[m\lambda\delta(e^{\frac{(\alpha+\delta)(\gamma+\sigma+\mu)}{m\lambda\delta}}-1)-(\alpha+\delta)(\gamma+\sigma+\mu)\right]}{m\lambda(e^{\frac{(\alpha+\delta)(\gamma+\sigma+\mu)}{m\lambda\delta}}-1)^2\left[\delta(1+\sigma/\varepsilon)+(\gamma+\sigma)\right]}$$

Remark 1. With changes of disconnect probability, we can get different values of threshold and densities of infected nodes in steady state. When μ increases, the corresponding λ_c rises and I^∞ decreases significantly, which shows that feedback mechanism helps contain the epidemic.

Remark 2. When $\mu=0$, the model yields the *SIQRS* epidemic without feedback mechanism, which shows the valid epidemic threshold consists with [2]. When $\mu=0$, $\sigma=0$ and $\alpha=0$, the model yields the standard *SIRS* epidemic with the valid threshold consists with [6]. Apparently, in the eco-limits of infinite network size the nodes grows to infinity, i.e. $N\to\infty$, then $\langle k^2\rangle\to\infty$, so the absence of an epidemic threshold is observed.

Conclusion

A modified *SIQRS* epidemic model with feedback-mechanism on the scale-free networks is presented. By mean-filed theory, we obtain the threshold and the endemic prevalence of infection. Theoretical analysis shows the epidemic threshold and the steady infection density of the system is virtually correlated with the feedback mechanism. Moreover, increasing the disconnect probability can result in the raise of infection threshold and the decrease of the population finally infected.

Keywords: Web Service; Access Control

Abstract. Access control is an important technique which is used to protect system resources from damage by unauthorized users. With the advantage of web services, the access control module was released as web services interfaces. In order to control accessing to system resources and take advantage of web services，this paper proposes the web service-oriented access control (WSOAC) model. The development of access control is firstly introduced; after that the authors describe this model with two levels—platform and tenant and then present the execution process. At last, the paper summarizes the characteristics of the model and the next step.

Introduction

Service-oriented architecture (SOA) can greatly enhance collaboration and information sharing capability of the companies or organizations. Its ideology is widely used in cloud computing—the emerging business model; however, there are still many critical issues that should be solved during the development especially the security in it [1]. Therefore, with the cloud computing technology to be applied to large-scale production, it is necessary to fully analyze and address security issues. However, in security field, there is still not a sound theoretical model to meet the needs of multi-tenant environment for accessing control services.

Researches on access control date back to the models of discretionary access control and mandatory access control addressed by U.S. Department of Defense. After that, Farraiolo et al [2] proposed RBAC model (role-based access control) in 1992; this model introduced the concept of roles between the user and the permission and soon became the research focus. On this basis, Sandhu et al [3] have proposed model ARBAC02 and model ARBAC97 [4]. For the SaaS model which enjoys the rapid development at present, the three current mainstream access control technologies (ie, DAC, MAC and RBAC) have their limitations. Literature [5] adopted a layered approach and proposed an access control method for SaaS platform on the basis of RBAC. Literature [6] also proposed an access control method for SaaS platform; this method disabled the role of inheritance and showed the user the accessing processes by UML diagram, but roles and tenants were in a multi-to-multi relationship and they might easily suffer from conflicts. A multi-tenant access control model was introduced in literature [7], but could not achieve role inheritance on the level of tenant.

In this paper, the authors design a web service-oriented access control model (WSOAC) against the weakness in multi-tenant cloud environments of the traditional RBAC model. This model, consisting of the platform level and the tenant level, efficiently deals with users' accessing public resources and tenants' exclusive resources and solves accessing isolation when users get access to different tenants' inner resources.

Web Service-oriented Access Control Model

Access control is to ensure that resources are only granted to authorized users, programs, and processes, and to protect resources from unauthorized access. Model is a simplified representation of objective entities in words, graphics, symbols, formula and solid models through people's thinking abstraction of the objective reality when they study and solve various problems in the

objective world. Access control model is the basic abstraction of access control fundamentals, including User, Roles, Permissions and Sessions.

Based on ARBAC02 model, this paper presents a web service-oriented access control (WSOAC) model to satisfy complex cloud system resource access control requirements under the cloud environment. Different from local systems, web service system realizes the isolation and share of resources access not only on tenants layer, but also on the platform layer. The overall configuration of a model is shown in the following figure.

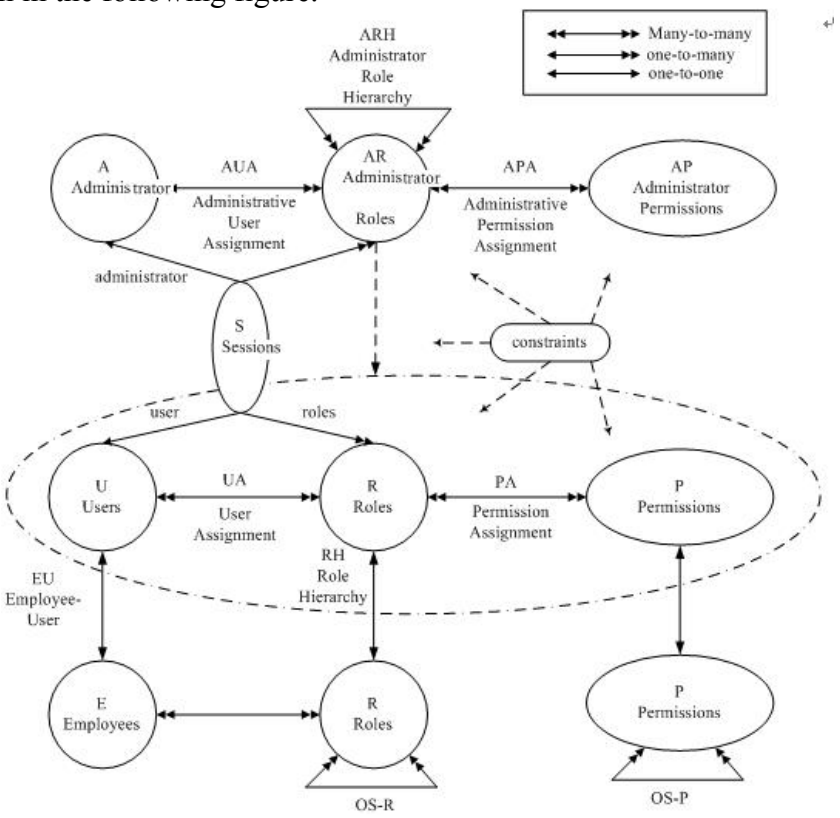

Fig.1 Web Service-Oriented Access Control Model

Web service-oriented access control model is divided into the platform layer and the tenants layer. The platform layer is responsible for tenant-level distribution of permissions and roles but can not operate within the system; the tenant layer empowers users to operate within the system via the user-role-permission mapping mechanism.

Tenant layer model

Firstly, the authors give the following definitions:

Def.1 Role

<Role>:=<r_ID, r_name, company_ID, roleList > (r_ID∈ComID ⋃ DeptID ⋃ PosID; r_name∈ComName ⋃ DeptName ⋃ PosName; company_ID∈ComID, roleList ⊆ roleSet)

Def.2 Permission

<Permission>:=<p_ID, p _name, resource_ID, description, company_ID, p_role>(p_ID∈PID; p_name∈PName; resource_ID∈ResID, company_ID∈ComID,p_role∈role_Set)

Def.3 User

<User>:=<u_ID, u_name, company_ID, u_role > (u _ID∈EmployeeID; u_name∈EmployeeName; company_ID∈ComID,u_role∈roleSet)

Resource directory, user and role management: the operation of their information-----create, retrieve, update and delete, and add the user to the role. After that, the permission of resource to the user or the role is authorized.

Platform layer model

In the service-oriented access control model, in order to assign a user within the tenant the roles and permissions, WSOAC model creates a manager-management role-management permission mapping relationship on the platform layer. The platform layer only implements the distribution and control of management role and management permission, and should not be to implement the distribution and control of operation role and operation permission. The definitions are as follows:

Def.4 AdminRole, inherited from Role

<AdminRole>:=<r_ID, r_name, company_ID, roleList > (role_ID∈AdminRoleID;

r_name∈AdminRoleName; company_ID∈ComID∪PlatformID, roleList ⊆ AdminRoleSet)

Def.5 AdminPermission, inherited from Permission

<AdminPermission>:=<p_ID,p_name,resource_ID,description,company_ID,

p_role>(p_ID ∈ AdminPermID; p_name ∈ AdminPermName; resource_ID ∈ ResID, company_ID∈ComID∪PlatformID, p_role∈AdminRole_Set)

Def.3 AdminUser, inherited from User

<AdminUser>:=<u_ID,u_name,company_ID,u_role>(u_ID∈AdminUserID;u_name∈AdminUserName;company_ID∈ComID∪PlatformID,

U_role∈AdminRoleSet)

Model execution process

As shown in Figure 2, the access control process perform as follows:

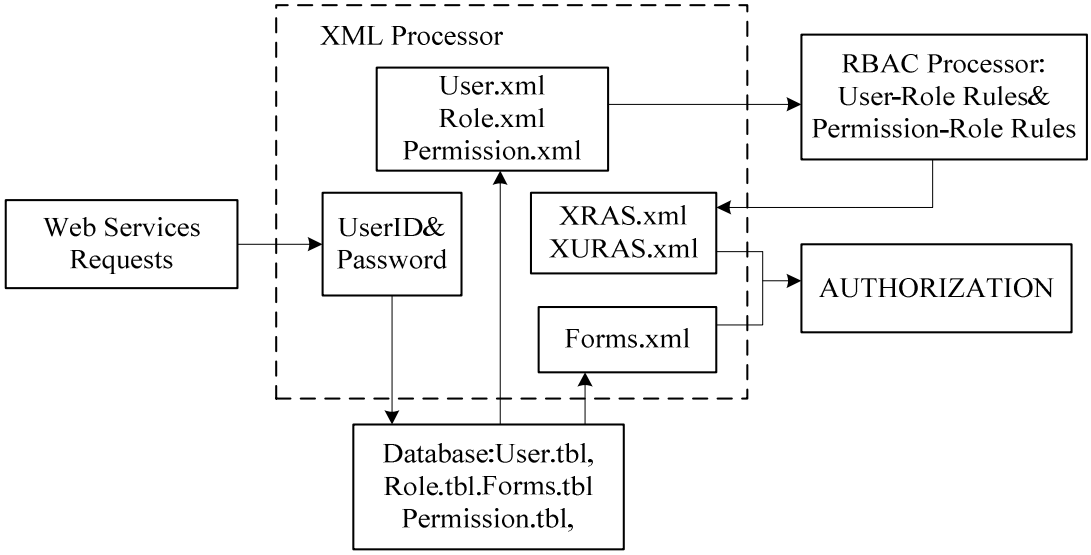

Fig.2 The architecture of web service-oriented access control

The dotted line is XML Processor. It processes the information in XML documents, extracts association as well, and then generates the corresponding XML document based on the XML schema. Once successfully checking each relevant XML document, XML Processor generates DOM tree, and then assigns the role permissions checking tasks to RBAC Processor. RBAC Processor contains RBAC module and associates the data items that are generated by RBAC. RBAC Processor implements the policy management and policy enforcement.

Policy management means that it will resolve DOM tree generated by the XML Processor to an internal data model in RBAC Processor, extract the information related to the user rights and then check the consistency principle of RBAC for verification. Policy enforcement means that RBAC module uses the legal information to manage the user's session. The initial session is automatically generated when a user just logs into the system, the initial session only activates the essential role currently, that is, the minimum set of roles.

The complete process of users' requested services is as follows:

(1) After receiving request by the user, the application service passes the request to XML Processor, and then analyzes it to obtain the user ID and password from the message and gets the appropriate rights from the database.
(2) XML Processor, after processing users' permission information, generates corresponding User.xml, Role.xml, Permission.xml according to various XML Schema, and passes these three XML documents to RBAC Processor.
(3) RBAC Processor passes the request and permission to access control system and checks the permission with the RBAC rules, then passes the processed result back to XML Processor and generate XRAS.xml, XURAS.xml
(4) Get the information of all the forms of enterprise application system from the database and generate Form.xml via XML Processor, and then generate the function tree corresponding to all the forms in users' permission scope by integrating XRAS.xml, XURAS.xml and Forms.xml.

The model involves service users, service developers and system administrators. Service users send requests with the information about their rights; service developers will write their own service permissions policy, no longer concern about the identity of the requester; the system administrators set up policy system of resources rights.

Characteristics of the model

Compared with other access control models for web services, WSOAC model has the following advantages:

(1) The role of inheritance and role management capabilities:
Role inheritance is intact and adapts to multi-tenant environment
(2) The independence&scalability of the system and flexibility&portability of security management:
WSOAC model is a model of a generic framework for web services applications, and does not depend on the structure of XML documents and concrete realization of the code. With the growth of Web services, system scalability increases. Meanwhile, the model adopts the service and service attributes to encapsulate; in this way can a more flexible and portable security management be achieved.
(3) Satisfy web services security applications:
Previous researches focused on the structure of an XML document, and the system did not focus on independence and scalability. In view of this weakness, this research, focusing on web services application environment, proposes service-level access control and service attribute-level access control mechanisms, thus making access control more granular in order to meet the practical application of the characteristics of Web services to work better.

Epilogue

Based on traditional RBAC model, this paper proposes a service-oriented access control (WSOAC) model. The model is divided into platform level and tenant level to meet the need of multi-tenant environment for multi-user access control, and then introduces the execution process of the model. However there is the drawback of not achieving the role's autonomous management. This is the focus of follow-up work.

Keywords: Art e-commerce; Trade process; Network; Security technology

Abstract. This paper expounds the concept of art electronic commerce, analyzes the connotation of art e-commerce, and introduces some related security technology from security problems in e-commerce transactions so as to effectively eliminate safety troubles in e-commerce activities, guide and promote healthy and rapid development of art electronic commerce in our country.

Introduction

21st century is an information century. The development of computer network makes further change in the connotation of information society. “Digital life would bring human into the information age. All kinds of modes are changing rapidly in the current society, forming a new pattern based on ‘bits’ thinking. ”said by American Negroponte in the book "Being Digital". Network is a 24-hour-open space, and its potential customers are throughout the world. Under the environment of network economy, e-commerce is the inevitable choice of our country’s enterprises, traditional industry in particular, for their integration into the global economy.

With the popularity of network technology and the development of art trades, the role of e-commerce in the field of art trades is becoming more and bigger. Through the network, art trades are going from professionals to folks. As the segmentation of electronic commerce, art e-commerce has changed the traditional art business operation mode, which greatly improved the efficiency of art business, and reduced the cost of art trade. It has gradually become a striking new art trading mechanism, and causes consumers’ attention. The analysis, comparison and research of art electronic commerce gradually become hot topics nowadays. However, due to the internet characteristics of openness, security problem has become the bottleneck which restricts the development of further electronic commerce. As a result, building a safe and reliable art electronic commerce application environment has become the key issue affecting art e-commerce development.

The connotation of art e-commerce

In the increasingly detailed social labor division, art e-commerce is like clothing e-commerce and tourism e-commerce, which belongs to the segmentation of e-commerce in concrete industry. We can refer to the concept of e-commerce for preliminary concept of art e-commerce definition, that is to say that art e-commerce refers to the business system with network as the main body, the Internet technology, art information database, electronic commerce bank or the third party payment as the foundation, using the most advanced electronic means to operate art industry and its distribution system. In essence, art e-commerce can be understood as an Internet platform provided for general art industry peers. Although art e-commerce is applied in art industry for only a few years, it has very strong development momentum. Art e-commerce has become a new mode of art information age, and the requirements of e-commerce security technology are growing in the process of art electronic trading.

From the above definition of art e-commerce, we can conclude that the connotation of art electronic commerce is that the emergence and development of information technology, especially of the Internet technology are the premise of art e-commerce carrying out; Masters of modern

information technology and art business theory and practice are the core of art electronic commerce activities; Series and systematic information base and electronic payment tools are the foundation of art e-commerce activities; Economic affairs activities with art trade as the center are the objects of e-commerce; Network security technology in the process of art e-commerce transactions is the key to art e-commerce activities.

Art e-commerce security issues

Generally, the information in art electronic commerce system can be divided into public information and private information. Public information refers to the information which need no encrypt in art e-commerce trade, such as art introduction and promotion information in art e-commerce site. Conversely, private information refers to as confidential information, for example, a customer's personal information or net bank password, etc. Art electronic commerce security problems are mainly for private information or confidential information.

A. Information disclosure, damage, and been tampered

Information disclosure mainly displays as the leakage of business secrets in art e-commerce, which includes two aspects: one is that trade content of both trade parties is stolen by a third party; the other is that the file one trade party provided for the other party is used illegally by a third party. Information destruction is mainly reflected in network hardware or software problems which may lead to trade information loss, fallacies and destruction of computer network itself by some malicious programs, such as virus, hacker intrusion, etc. In addition, in the process of art e-commerce transactions on the computer network, information transmission may be unauthorized tampering, deleted, or be used multiple times because the network has the characteristics of openness, and thus lose information’s authenticity and integrity.

B. Identification

Identification in art electronic commerce involves two problems: first is that without identification, the third party is likely to counterfeit trade party’s identity, destroy trading, and corrupt one fake party's credibility or steal art trading results; second is non-repudiation. Both parties should bear some responsibility for their actions, and the information sender and recipient cannot deny that. Identification is to prevent the denied behavior of counterfeit and trading in art e-commerce activities.

C. Art e-commerce transaction security

Art e-commerce transaction security refers to all kinds of security problems of art business activities in the process of online transactions. In order to ensure orderly art e-commerce activities, implement the electronic commerce’s confidentiality, authenticity, integrity, reliability, and prevent the denying, real-name system, certification system and certification system, accelerate the construction of legal system, promote blacklist system, and intensify illegal punishments, etc.

Main security technologies used in art electronic commerce

According to the domestic and foreign academic research on e-commerce security issues, there are many corresponding solutions to a lot of security threats in the process of art e-commerce transactions, which involves mainly security technologies like data encryption technology, firewall technology, digital signature technology and security agreement, etc.

A. Data Encryption

So-called data encryption is to transform an information (or called plain text) by encrypted key and encryption function transformation to meaningless cipher text, and the receiver decrypts cipher text by decryption key to reform plain text. In art e-commerce, data encryption technology is the basis of other security technologies, and is the most main security measure. Trading party may use it in information exchange stages according to needs. At present, there are two types of encryptions, namely, symmetric encryption and asymmetric encryption.

(1) Symmetric encryption

Symmetric encryption is also called private key encryption, which refers to the both sides of the encryption method use the same key for encryption and decryption. Key security exchange is the core of symmetric encryption, and private keys are exchanged. Symmetric encryption method is used to simplify the processing of encryption. Every trade party doesn't need to study and exchange dedicated encryption algorithms, but to use the same encryption algorithm and only exchange sharing private keys. Commonly used symmetric encryptions are DES, IDEA, RC2, RC4, SKIPJACK, RC5, and AES algorithm, etc. More famous symmetric encryption algorithm is proposed by the national bureau of standards DES (Data Encryption Standard). DES belongs to grouping encryption algorithm, namely data encryption in 64 bits for the grouping. Its symmetry displays in using the same algorithm for encryption and decryption. Its key length is 56 bits (because each 8 bits are used for parity). The key can be any number of 56 bits, and it can be changed at any time.

A problem of symmetric encryption is that it is unable to identify the initiator or trade final party. Because the two sides share the same private key, so any information of both trade sides is sent by this encrypted key to each other.

(2) Asymmetric encryption

Asymmetric encryption is also known as public key encryption and asymmetric encryption system is put forward with the fatal weakness of symmetric encryption system. Unlike symmetric encryption algorithm, asymmetric encryption algorithm needs two keys: public key and a private key. Public and private keys are a key pair. If use public key to encrypt data, it can be decrypted only with the corresponding private key; If use private key to encrypt data, it can be decrypted only with the corresponding public key. The public key is open outward and the private key is reserved. RSA (Rivest Shamir Adleman) algorithm is the most famous within the territory of symmetric encryption algorithm. The basic process of users' exchange of confidential information by using this scheme is: trade party A generates a pair of keys and take one of those as a public key to other trade party publicly, and trade party B gets the public key and encrypts the confidential information by using it and then sends to trade party A; Trade party A uses the other private key to decrypt the encrypted information. Trade party A can only use its private key to decrypt any information encrypted by the public key.

In order to give full play to symmetric and asymmetric encryption systems' respective advantages, these two kinds of encryption systems are usually applied together in actual application, such as: using DES to encrypt information, and RSA is used to transmit the keys in symmetric encryption system.

B. Firewall technology

Firewall is to establish the corresponding network traffic monitoring system in network boundary to ensure the security of computer network. It is a kind of control technology, which can be either a software product, or make or be embedded in some kind of hardware products. All transport information or information issued from the Internet must go through a firewall. So the firewall will protect the security of e-mail, file transfer, remote login, and exchange of information between particular systems. The main ways to realize firewall technology are: packet filtering and proxy service.

(1) Packet filtering

Packet filtering is a firewall based on the router. It sets a access list or blacklist in the network router according to network security policy, namely with the help of IP address in data packet to determine what type of information to be allowed to get through the firewall, and what kind of information to be avoided to pass. The responsibilities of the firewall are to check in and out of the router's grouping and filtering according to accessing table (or blacklist). The firewall is simple, but can't effectively prevent illegal attacks. At present, 80% of the firewalls use the technology.

(2) Agent service

Agent service is a kind of firewall based on proxy service. It has high safety, strengthens the function of identity authentication and audit trail, but it is slower. The audit trail is to provide a

complete record about the usage of network resources in order to complete supervise and control the network. Through continuous collection and accumulation of complete event records accessing network, perform audit trail selectively on some of them, find possible illegal acts and provide strong evidence, then sent the relevant information such as the blacklist secretly to firewall on the net. Although the firewall can implement effective protection of external network blows, the safety of internal information transmission network is powerless. There must be some dynamic security technologies to realize the security of e-commerce.

C. Digital signature technology

Encryption technology only is not enough to ensure the security of business information. To ensure information integrity, digital signature technology occupies an irreplaceable position. At present, the applications of digital signature are mainly digital abstract, digital signature and digital time-stamp technique.

(1) Digital abstract

Digital abstract is to get information of certain length based on one-way Hash function transform operation to an original message. The abstract is one-to-one correspondence with the original information, that is, different original information is bound to get a different abstract. If the integrity of the information is destroyed, the information will not be able to get through the original information verification, and become invalid information. The recipient can then choose to no longer trust the information.

(2) Digital signature

Digital signature is actually using non-repudiation information of public and private key encryption technology and its concrete process is: the file sender generate a digital abstract from a file, encrypt it with its own private key, and form a digital signature. The encrypted digital signature file is send to the receiver with the original file as attachments. After the receiver receives information, decrypt it with the sender's public key. If the correct summary is worked out, this abstract can make sure that the original file has not been changed. So the information is true to be sent by the sender. Then it realizes the identification and non-repudiation of the original documents.

(3) Digital time-stamp

Digital time stamp technology or DTS is a third party service to sign date for digital file or trading information. Essentially digital time-stamp technology is the same as digital signature technology. After sealed by digital time-stamp, information cannot be forged, tampered with, and denial and it provides reliable information time information for the reference.

D. Security protocol

In addition to various security control technology, the operation of electronic commerce also needs a set of perfect security trading agreement. The complexity and the security of each different deal are not identical, so different applications have different requirements for the agreement aims. At present, more mature agreements are SET, SSL, S - HTTP, etc.

(1) SSL protocol

Secure Sockets Layer (SSL) protocol is between TCP/IP and various application Layer protocols to provide security support for data communication, which is a network security protocol firstly applied in international electronic commerce. Because SSL is located between the transport layer and application layer, SSL is a good way to encapsulate application layer data without changing the application program in application layer, and it is transparent to the user. At the same time, SSL needs only one "handshake" process to build a secure communication channel between client and server, and ensure the safety of data transmission. The SSL protocol, however, has some problems, such as only support both sides certification. When multiple electronic trading is involved, SSL protocol cannot coordinate various security transmission and trust relationship.

(2) SET protocol

Secure Electronic Transaction (SET) protocol is a safety standard used in the Internet on the basis of bank card online trading. SET is mainly designed to solve the users', businessmen's and banks' payment transactions through credit card, and to ensure the secret command, payment process, legal status of merchants and cardholders, and its operability. SET provides authentication

between consumers, businessmen and banks, ensures the safety of transaction data, complete reliability and non-repudiation of the deal, and especially avoids the bank card number exposed to businessmen and consumers and supports the three parties' authentications etc. So it is widely applied in the field of e-commerce security, but SET protocol is too complex, and there are still many problems in actual application.

(3) S-HTTP protocol

S-HTTP (Security HTTP) is a high-level protocol constructed on HTTP protocol. S-HTTP supports a variety of ways to encapsulate information which includes encryption, signature, and certification based on the content of MAC, and supports that one message is repeatedly encapsulated and encrypted. In addition, S-HTTP protocol supports RSA and Kerberos key exchange, and provides a flexible programming environment for programmers. S-HTTP allows the user to generate a digital signature on each message, but S-HTTP protocol is powerless for the attacks from the bottom.

Conclusion

This article mainly expounds the concept and connotation of art e-commerce, analyzes the security technologies in current art e-commerce: data encryption, firewall technology, digital signature technology, as well as security agreement, and points out their use range and their advantages and disadvantages. Of course, the security of art electronic commerce is complicated system engineering. Only to guard from a technical point is not enough. In addition to technical research and application, the construction of social cultural environment should also be included, that is the Internet culture construction and spread of art e-commerce legislation and information morality and ethics to regulate all kinds of problems in the rapid development of art e-commerce in the real world, so as to guide and promote healthy and rapid development of art electronic commerce in our country.

The Application Design of Personalized Recommendation system Based on Data Mining to E-commerce

Li Sun

Hang Zhou Vocational & Technical college, Hang Zhou City, China

E-mail: lisun30@163.com

Keywords: Data mining, E-commerce, System architecture, Freakommendation

Abstract. Personalized recommendation application system of product and service is a valid tool to boost sales in both online and offline business. It has been reported and has been our experience that algorithmic –modeling phase occupies at most 20% of the effort in a data–mining project. The other 80% is how to put the "model" into practical application. The implementation process of personalized recommendation system based on data mining to E-commerce was discussed in this paper. We also proposed architecture of the system, described the application of technology, designed some features of the function modules.

1. Introduction

As IT technology accelerating, the world's economic modes have been undergoing tremendous changes. E-commerce, which brings all types of business activity online, is the most significant reform in recent 20 years that changing human's life greatly. While huge business user data accumulated, the owner will face losing control of the store online. And as salesman can not give customers suggestion face to face in E-commerce dealing, so we turn to data mining technology for personalized product recommendation [1]and business process transformation, which compares multiple customers' data, collected via registration record, questionnaires, web log files, basket-to-buy rate, and finds those with similar tastes. Generally the typical recommendation tasks in E-commerce include: helping new and infrequent visitors, building credibility through community, enticing customers to come back, cross-selling, and building long-term relationships.

2. Introduction of data mining techniques for achieving recommendation system

Data mining is sorting through data to identify patterns and establish relationships. Data mining techniques are used in a many research areas, including mathematics, cybernetics, genetics, marketing, Web mining, enterprises' management information system and so on. The Cross Industry Standard Process for Data Mining (CRISP-DM) defines six phases for data mining that is business understanding, data understanding, data preparation, modeling, evaluation, deployment. Six common algorithms are involved in data mining, they are:

(1)Association rule learning looks for patterns where one event is connected to another event.

(2)Collaborative filtering is a method of making automatic predictions (filtering) about the interests of a user by collecting preferences or taste information from many users (collaborating). The underlying assumption of the collaborative filtering approach is that if a person A has the same opinion as a person B on an issue, A is more likely to have B's opinion on a different issue x than to have the opinion on x of a person chosen randomly.

(3)Classification is the task of generalizing known structure to apply to new data. For example, an e-mail program might attempt to classify an e-mail as "legitimate" or as "spam".

(4)Clustering is the task of discovering groups and structures in the data that are in some way or another "similar", without using known structures in the data.

(5)Sequence or path analysis looks for patterns where one event leads to another later event.

(6)Forecasting aims to discover patterns in data that can lead to reasonable predictions about the future.

Recommended system must take into account the accuracy and timeliness. A good system may be combined with a variety of methods and techniques and let them learn from each other.

3. Characteristics of data mining in E-commerce

Data mining to E-commerce is the process to discover and extract implicit marketing mode by collecting website documents and services information. It targets at a large number of heterogeneous, distributed web documents which might be web log files or figures logically consisting of document nodes and hyperlinks.

As compared to ancient or shielded legacy systems, data collection to E-commerce can be controlled and reliable to a larger extent. We have the opportunity to design systems that collect data for the purposes of data mining, which will ease the integration with existing processes. Data are collected electronically, rather than manually, so less noise is introduced from manual processing. E-commerce data are rich, containing information on prior purchase activity and detailed demographic data. But on the other side, unlike fully structured data in traditional databases, the data of E-commerce platform has small correlation with data mining content, and highly dynamic. Its greatest feature is semi-structured without strict structure model. Data mining to E-commerce is more complicated than to a single data warehouse.

4. The implementation process of personalized recommendation system based on data mining technology

A typical recommendation system includes online interactive data collection, database processing, understanding of business rules, data mining process, recommendation model establishing, recommendation engine [2], as Fig.1 below. The form of recommendations, including recommended product to the customer, providing personalized product information, and other customers likes and dislikes and so on. Data mining part is the analysis of customer profiles generation process, using data mining techniques to identify customer data rules and patterns for recommendation system. The commercial domain knowledge and methods require the interactivity. The precise rules and patterns is crucial, and should be interacted with involving business domain knowledge and methods.

4.1 Data sources and arrangement

Personalized customer recommendation data source has the following three categories: one is the kind of content and product data capacity, including login records, click rates, browse paths and purchase records, etc., which exist in the E-commerce platform database with daily size of the TB bytes; The second category is the customer preference data on the partner network, such as browsing, collection, purchase and other data. This part of the data has the daily volume of the GB level scale. This two types of the most recent data mentioned above from the consumer are the core of e-commerce data. The third category of data is from the SCM, ERP, CRM information systems' historical data, such as customer transaction records, vendor records, assessment records, product costs, standard costs, forecasted orders costs, inventory, logistics information, orders forecasting, profitability analysis, etc.

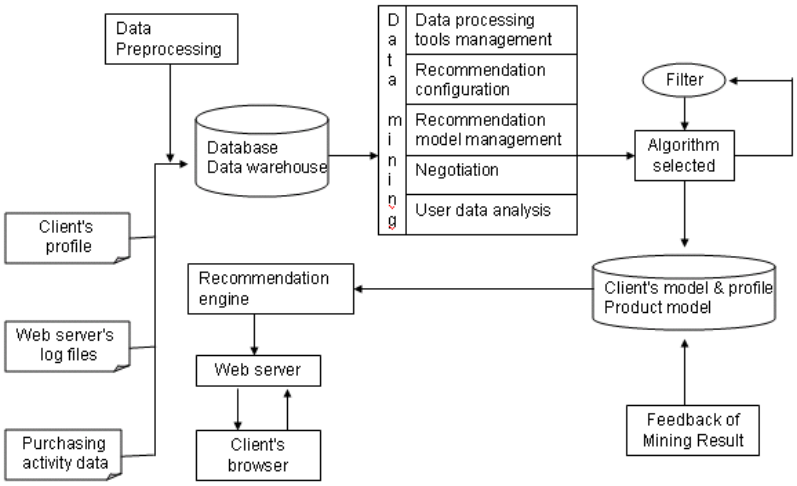

Fig1 The system architecture of E-commerce recommendation system based on data mining

We arrange the data above to establish commodity data item file with commodity characteristic number and feature weights. Also we build customer profiles database. It is composed of customer feature information and behavior data. Customer feature data items' files include user registration information, user access path to business platform, server logging files, recording customer inquiries, status. Customer behavior data items' file consists mainly of market data, including user purchasing behavior, commodity item information, E-commerce site information and etc.

4.2 Building customer prediction model

This work is providing a static data set, removing some of them, thinking of ways to use the remaining portion of the data to recover the removed data while making recovery error to the minimum. According to algorithm thinking, we build customer prediction model based on collaborative filtering algorithm and content-based algorithm. In practice, these two ideas can be further classified into black box and white box recommended modes. Black box mode does not consider any specific recommended content, but take the use of machine learning, data mining and other statistical methods and artificial intelligence methods [3] to analysis the data, establish relevant models and optimization objectives. The white box recommended process also uses machine learning and data mining algorithms.

Black and white box recommendation mode does not require too much knowledge of the field or manual intervention to build such a prediction model. But we meet challenges of freakommendation, macro and micro paradox while running black box recommendation mode. Freakommendation refers to the strange recommended result, such as. a similar association of flowers and horror films which leads to a lot of users recommended discomfort. It has a very negative impact on trust and psychological feelings. Macro and micro paradox refers to the phenomenon that as data growing, the entire recommendation system indicators will be getting better and better, but the prediction model inclines to give some mediocre and conservative recommended contents to the VIP. So in practice, we tend to take a so-called mixed models with the integration of two modes' advantages in order to achieve a better recommended results.

4.3 Forecasting the next change in the system by taking the given data set as a self-consistent system.

This step is to form knowledge from information. Forecasting will optimized the forecasting indicators in the time dimension based on prediction model [4]. It is more complicated than building prediction model because psychological and social factors must be considered as time going. To solve forecasting problems, it is not enough to start only from the given data and prediction models, but also needs to integrate data from other sources, require prior knowledge, or even take a little user's cognitive and mental models.

4.4 Making personalized recommendation

According to customer requests and recommendation strategies, we call the relevant data processing tools to get recommendation result by considering customers' background information. Input elements include customer identification mark, customer type, customer score sheet, customer profiles, commodity item files, customer specified number of neighbors and the maximum recommended number. Output elements include recommended product group and promotional strategies. This step is to form business process system from knowledge. The system should have the recommended areas of knowledge, but also be able to understand its every customer. The system is able to self-start while being able to grow, evolve and learn by itself. The system is not strictly defined, and its basic technical architecture may not be limited to the current popular personalized recommendation system frameworks, techniques and algorithms [5].

4.5 Design of recommendation engine

In actual operation of e-commerce, the data mining algorithms need to be planted into the bottom frame of recommendation engine from basic forms of service which means recommendation engine does not directly provide recommended result. Because precise marketing recommendations vary greatly according to the scenarios and requirements. So users need to add recommendation dimension parameters to recommendation engine to reach customer's true needs. It aims to provide solutions of achieving personalized, intensive level service concept for the seller.

5. Suggestion and conclusion

We noticed that E-commerce recommendation framework would surely increase personalization by collecting and processing additional data of customer's behavior automatically which also affects the actions of customers. However in the future of the internet era, personalized recommendation system may not become platforms like Amazon, Facebook, Google etc., but it surely become the core competitiveness for all the E-commerce platforms.

Keywords: White-box testing; Black-box testing; Web Application; Security

Abstract. Contrary to high false positives rate of use White-box testing tools for Web application source code security and unable to locate vulnerabilities of use Black-box testing tools for Web application security, propose an effective method for combine White-box and Black-box testing tools of Web applications. This method will put the new technology of "Associated Files Matching Engine" into White-box testing tools, this test result and Black-box test result will be statistical analyzed and combined. Argumentation show, this method reduce the positives rate of White-box test result and be able to locate vulnerabilities where it is in file.

Introduction

Continuous innovation and development of Internet applications has greatly promoted the development of social progress and human civilization, has become one of the main driving force of social development. Information and network security is also facing unprecedented serious problems, the challenge facing the network security become increasingly severe, people increasingly focus on the network security issues.

With the threshold of excavating operating system vulnerabilities have gradually increased, application security has become short board. Network intrusion, large-scale worm propagation, denial of service system such as other issues are triggered by the application software vulnerabilities. Current software development model is a very important reason of arising vulnerabilities, for example, architecture design flaws, coding vulnerabilities, inadequate safety testing. Simultaneously, code security detection technology uneven. In security code detection method, definition of code defects, code defect classification, code defect risk level and other aspects did not unified. In support environment, it still stay on the basis of common defects library, it cannot combine with existing application systems. And cannot trace the code vulnerabilities of between different versions of the application system, cannot effectively control code security. This is an urgent need to strengthen the system security testing work, to detect system vulnerabilities, improve system security.

In the usual sense, threaten of network security is the vulnerabilities of Web application. Currently, Web application vulnerabilities detection methods are Black-box testing and White-box testing. Black-box testing [1] detect Web application security when Web application run, this detection dependence on external environment and test cases, and it has a certain degree of uncertainty, but it has the advantage of low false positives rate. White-box testing is static source code analysis technology, it progressive analyze the source code of Web application, use symbolic executing techniques [2], data flow analysis [3] other analytical methods find out security flaws of code, this detection can avoid these shortcomings, but it has the disadvantage of high false positive rate.

Evaluating the White-box testing has two important indicators [4]:

(a) False negatives rate, the rate of the tools cannot find the security problems of Web application system.

(b) False positives rate, the rate of the tools find the security problems what it is not really problems in Web application system.

According to the above two criteria, existing white-box testing tools are present its own deficiencies and defects. How to effectively reduce the rate of false positives White-box testing? How to effectively locate the vulnerabilities of Black-box testing? This article discusses these two issues, and proposes solution.

The White-box testing

White-box testing mainly refers to the source code static analysis detection [5]. The Static analysis method scans the program code directly, extract the crucial grammar, explain the grammar, and understand the behavior of program. Then according to the preset vulnerability signatures, safety rules detect vulnerabilities [6].

(a) The lexical analysis

The lexical analysis is the earliest one of the source code analysis technology, it only detects the grammar. The lexical analysis divides the program into a fragment, then every fragment with a "suspect database" to compare, if it belongs to suspect, then further implementation of heuristic judgment.

(b) The rule checking

The program itself security is described by safely rules. The program itself exists some programming rules, these are some general safety rules, also known vulnerabilities mode. The rule checking will describe these rules by specific syntax, received by the rule processor, and converted to the date what it can be accepted by analyzer, then be compared and tested to the behavior of the program.

(c) The type inference

Automatic deduce the type of the program variables and functions to determine whether access to variables and functions in line with type rules. The type inference of static vulnerabilities is derived by stereotypes assertions, deduction and checking rules of three parts. The stereotypes assertions defines the initial type of variables, the deduction rules provide the rules set of inference system, the checking rules judge determination corollary is "good behavior".

(d) The symbolic executing

The basic ideal of symbolic executing that it converts the value of the variable in the program logic into abstract symbols, simulate path sensitive program control flow, constraint solving method, tests whether there is the possibility of error. Starting from conditions before the execution of the program P, in a program point in a program, can launch the constraint c1^c2^…^cn, so at this point have P^c1^c2^…^cn->R, R is meet the conditions when the program end.

Existing white-box testing tools are contains one or more of the combination of static source code security detection technology. For example Fortify SCA tool, contains the data flow engine, semantic analysis engine, the configuration analysis engine, etc. Because after the White-box testing , lack of the source code to verify safety defects. So the White-box testing can detect a lot of vulnerabilities of source code, but do not know what loopholes are real, what loopholes are important, what loopholes need to repair immediately. See Figure 1.

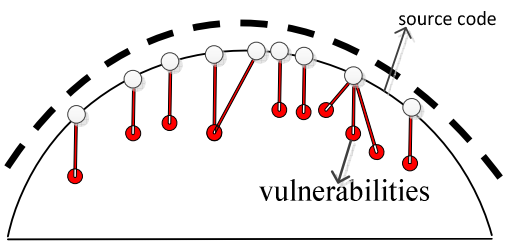

Fig.1. The abstract model of White-box testing

The Black-box testing

The Black box testing is the program as a cannot open the box, regardless of the program's internal logical structure and internal characteristics, tests program directly [7]. Black-box testing tool is tested in the absence of the source code, soon after get the test result cannot determine the cause of the vulnerabilities, produces by which a piece of code? See Figure 2.

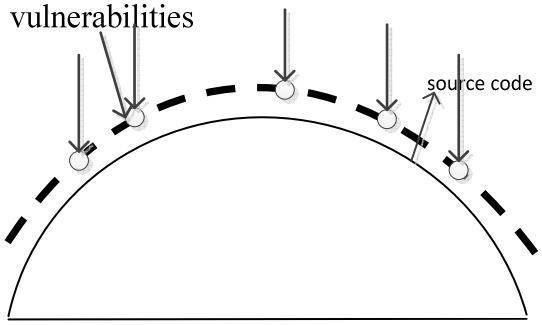

Fig.2. The abstract model of Black-box testing

Combining White-box and Black-box testing

Aiming at the shortcomings of the above white box testing and black box testing, Design a kind of white and black box combination analysis method, the analysis method is mainly the result of white box testing and black box testing effectively, quickly locate a vulnerabilities on the number of lines of code rule out false positives. See Figure 3.

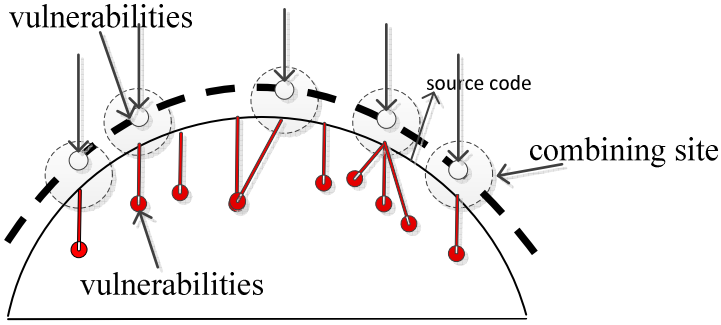

Fig.3.The abstract model of combining White-box and Black-box testing

The White-box testing results contain {the vulnerability type, the file where the vulnerability locate, the line of the file where the vulnerability locate} this several important conclusions. The Black-box testing results contain {the vulnerability type, the files where the vulnerability locate} this several important conclusions.

Here we have an example of SQL Injection result:

The SQL Injection result what tested by White-box testing, a set W is {{SQL Injection, file 1, line n},{SQL Injection, file 2, line n}……}.

The SQL Injection result what tested by Black-box testing, a set B is {{SQL Injection, file a}, {SQL Injection, file b}……}.

The set W and the set B have a certain intersection, but the existing methods cannot be selecting the intersection of set W and set B.

In the White-box testing, to scan the file where the SQL Injection vulnerability locates and uses the technology of “Associated Files Matching Engine” to scan the whole project. Then enumerating file collection F {file n1, file n2, file n3……} what relate to the file where the SQL Injection vulnerability locates.

The "Associated Files Matching Engine" mainly uses the file scanning, rules checking such as technology, to scan the entire project and find out other files which are associated with the file where the vulnerability locates.

(a) The file scanning

Through the file with the formation of a file stream to read out, and then to traverse the entire file. Using fuzzy matching technology to look for the file which contains the keyword (in file 1 of vulnerability). If the file includes the keyword, the file will be selected out. If the file does not includes the keyword, then scanning the other files in the program.

(b) The rule checking

Through the file scanning technology, to find out the key words related files collection {file f1, file f2……}. Then check the each file which is in the collection using the rules. First, selecting file f1, then locating the position of the keywords in the file f1 and checking use the rules. Centering on the position of the keyword, rule checks within a certain range. If within the scope of the definition, look for to the keyword matching rules, will file selected. If there are no rules in the library to find keywords, to file scanning techniques of other files in the collection of rule processing. Finally it is concluded that the associated files collection {file a1, file a2……}.

The flow chart of "Associated Files Matching Engine" sees Figure 4. Using the keyword to scan the all file in whole project and simultaneously using the rule base (the keyword of struts and spring) to matching. Last enumerating the associated files.

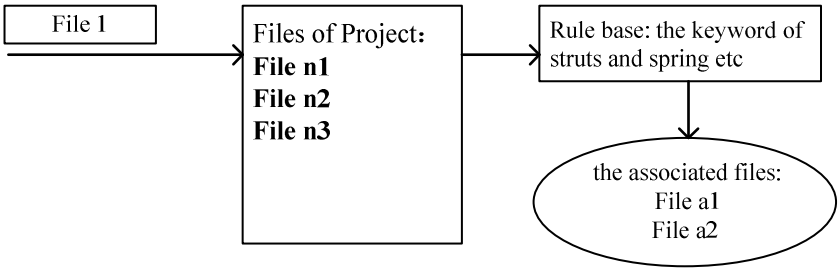

Fig.4.The flow chart of "Associated Files Matching Engine"

See Figure 5. Black-box testing results, White-box testing results, files associations through vulnerability type to match, White-box testing results and files associations through the file (file 1) where the vulnerability locates match. Finally, iterating through all the black box testing results (SQL Injection). Using the file (file b) which is tested by Black-box testing compares to the file which associates with file 1, if traversing all the Black-box testing results do not find out the file which associates with it, so the vulnerability which is tested by White-box testing is not real.

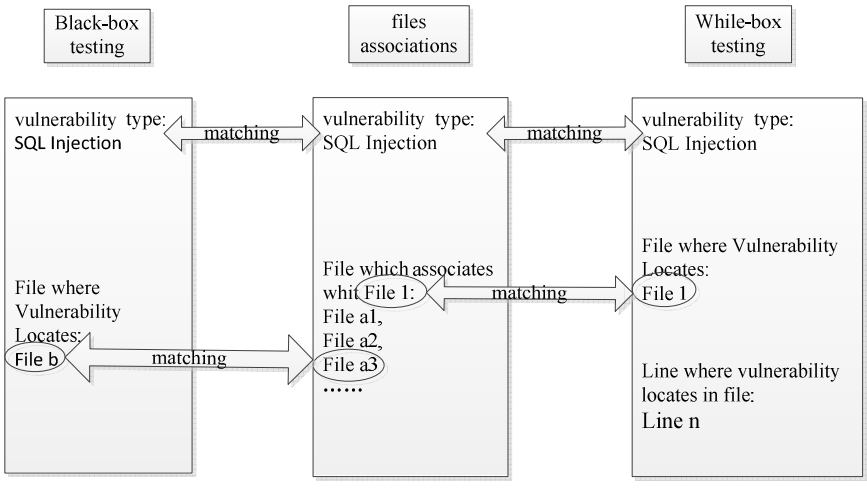

Fig.5.The chart of matching

Conclusion

This paper proposes a method which is combining White-box testing and Black-box testing of Web Applications security. This approach has been demonstrated on. The method can effectively reduce high false positives rate of use White-box testing tools. The next step of research is focused on the technology of “Associated Files Matching Engine”, through into different technology, To effectively improve the efficiency and accuracy of “Associated Files Matching Engine”.

Keywords: Received Signal Strength Index; Performance Comparison; Wireless Sensor Networks; Distance Estimation

Abstract. A lot of the wireless sensor network applications call for sensor nodes to be applicable to any environment. RSSI-based measurements implement conveniently and are cost-efficient and power-efficient in practice. This paper compares the distance estimation performances based RSSI in three different environments by experiments and discusses their characteristic in detail. We carry out a large amount of repeated experiment based on RSSI in three kinds of environments over the 2.4GHz wireless channel. Subsequently, we focus on studying and discussing data analyses of RSSI and possible improvements in each environment. Experimental results demonstrate availability and feasibility of RSSI in outdoor and indoor environments.

Introduction

A lot of the wireless sensor network(WSN) applications, for example, intrusion detection[1], fire prevention[2], environmental monitoring, and military safety[3], call for sensor nodes to be applicable to any environment[4]. Location of sensor nodes is a fundamental issue in WSN. In the last few years, localization of WSN has attracted a large amount of interests for researchers range from wireless communications to data processing[5]. Nevertheless, range estimation is foundational to a location based service system. A lot of distance estimation methods such as time of arrival(TOA)[6], time difference of arrival(TDOA) [7], angle of arrive(AOA)[8], and received signal strength indicator(RSSI)[9] are proposed. RSSI-based measurements implement conveniently and are cost-efficient and power-efficient in practice, because it doesn't require extra hardware design. Others approaches are costly and need extra hardware embedded in device.

RSSI-based localization is an simple techniques to infer the location of the unknown sensor nodes because they has merely low demand on the hardware module[10]. In the field of RSSI-based localization, considerable amount of research has been done. In different environments, RSSI-based localization suffer from a variety of effects. In this paper, we compares the distance estimation performances based RSSI in three different environments by experiments and discusses their characteristic in detail. We use many sensor nodes, which employ a 2.4GHz low power radio chip CC2430 based ZigBee[11]. We carry out a large amount of repeated experiment based on RSSI in three kinds of environments over the 2.4GHz wireless channel[12]. Subsequently, we focus on studying and discussing data analyses of RSSI and possible improvements in each environment. It is shown that distance estimation based RSSI is availability and feasibility in outdoor and indoor situation.

The remainder of this paper is organized as follows. In Section II, we introduce the Measurement equipment, environment and propagation model, Section III presents experimental performance evaluation, conclusions will be given in Section IV.

Measurement & Methodology

For our Experiment, The sensor node uses the reinforced 8051 processor which can run in high energy efficiency and low power dissipation, and have 128kB flash memory and 8kB RAM. Each

sensor nodes employs a CC2430 transceiver, which is a system-on-chip solution and use O-QPSK modulation with DSSS at 250kbps, as its radio frequency and was assigned to transmit continuously with a data packet in the 2.4 GHz band. As the receivers, we put to use other sensor nodes to gather the RSSI of the packet. CC2430 is computed over 8 symbol periods, which possess a integrated register named RSSI_VAL to store RSSI value, and can extract the power value on RF pin using the following equation:

$$RSS = RSSI_VAL + RSSI_OFFSET[dBm] \tag{1}$$

(a) Playground

(b) corridor

Fig.1. Measurement Environment

The RSSI_OFFSET is set to -45dBm that is popularly used in WSN. The receiver sensor nodes is designed to collect the RSSI every 0.5 seconds that achieve a continuous sampling of the channel.

We implement the experiments in three different environments as described in detail next.

Location I: One playground fields measuring 200×200 m. As shown in Fig.1.(a), the playground are flat and planted with short grass.

Location II: A corridor area measuring 150×1.5 m. As shown in Fig.1.(b), the corridor have occasionally people walk through.

Location III: One indoor rooms is a three dimension structure measuring 7.5m(L)×5.3m(W)×2.89m(H). there are several desks, chairs and cabinet on the wall in room.

To measure the communication characteristics at a local area, we firstly estimate parameters of the radio propagation model. Assuming the m reference nodes are positioned at (x_r, y_r), r=1,2,…,m. and the n unknown nodes are positioned at (x_u, y_u), u=1,2,…,n. The log-distance path loss signal propagation model is given as follows .

$$P_t - P_0(d_0) - P_r(d) = 10\eta \log(\frac{d}{d_0}) + X_\sigma \tag{2}$$

Where, P_t is the transmitted power at transmit node, $P_0(d_0)$ is the path loss at the reference distance d_0, $P_r(d)$ is the received signal strength at distance d, d is the distance between the reference nodes and unknown node, d_0 is the distance between the reference nodes and reference point, which is common assigned to be 1m. η is the path loss exponent varying with different environment and X_σ is a Gaussian random variable.

Assuming P_t-$P_0(d_0)$=A, each unknown sensor node (x_u, y_u) have k reference nodes, Using Equation (2) ,we can have matrix equation as follows.

$$\begin{bmatrix} P_{r_1}(d) \\ P_{r_2}(d) \\ \dots \\ P_{r_k}(d) \end{bmatrix} = \begin{bmatrix} 1 & -10\log d_1 \\ 1 & -10\log d_2 \\ \dots & \dots \\ 1 & -10\log d_k \end{bmatrix} \begin{bmatrix} A \\ \eta \end{bmatrix} + \begin{bmatrix} X_{\sigma_1} \\ X_{\sigma_2} \\ \dots \\ X_{\sigma_k} \end{bmatrix} = BX \tag{3}$$

By least-squares resolution, we obtain as follows.

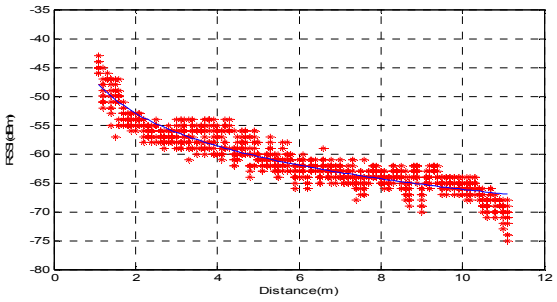
$$X = (B^T B)^{-1} B^T P \tag{4}$$

From equation (4), we can solve vector X. The parameters of communication model, A and η can be obtained from X. The more is the number of reference nodes, the higher accuracy is the result for A and n.

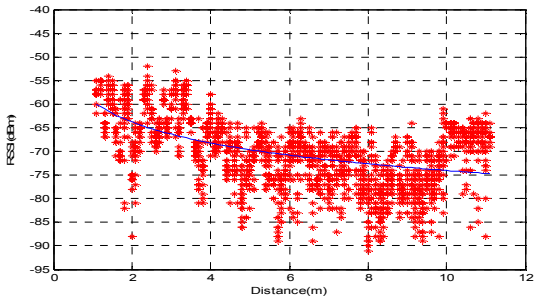
Performance comparison

We quantify the performance of RSSI employing our sensor nodes based ZigBee. To reduce the RSSI instability and attenuation, the nodes, which attach to a height of 1.2m tripod over the ground, equip with omni-directional antenna that can transmit signal in all directions with 0 dBm. Each measurement situation is deployed a lot of sensor nodes to transmit data packets and other neighbor nodes senses the packets containing the RSSI information and forwards this packets. In each of experiment, we use coordinator node gather packet ,via USB interface, to laptop.

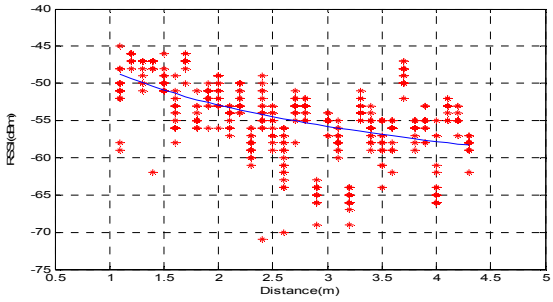
In our experiments, repeated observations about RSSI is measured from one meter to eleven meters spaced 0.1m for one hour. we analysis distribution of RSSI from different environments. The figure is obtained with range(m) along x-axis and RSSI along y-axis. Fig.2 show that the RSSI values were observed in outdoor and indoor and RSSI varies with distance, which shows that RSSI value in different environments has much fluctuation. We select different environments to analysis relation between RSSI and distance. In Fig.2(a), it is to be observed that the RSSI value vary dramatically with distance increasing under flat open square. It is noticeable that from the range of RSSI at each distance point only few different values were measured. However, In Fig.2(b) , It is obvious that a lot of different RSSI values were measured and that the RSSI values vary a few extent under identical conditions at corridor. Fig.2(c) show similar characteristics. Fig.2(b) and Fig.2(c) also show too much fluctuation between RSSI and distance in indoor and corridor which exist a few obstruction and walking men. However, The data analyses in above section have similarity and imply that using RSSI is availability and feasibility in outdoor and indoor environments.



(a) Playground



(b) corridor



(c) Indoor

Fig.2. RSSI distribution in different environment

In different environments, the statistical properties require to be measured. A comparison of the statistical terms shows that three kinds of measurements exhibit similar characteristics as depicted in Table1.

Table 1. RSSI with different orientation

Statistics	playground	corridor	indoor
A(4.3m)	-47.8549	-60.0172	-48.0518
A(11.1m)	-47.2205	-59.3701	-
n(4.3m)	1.7254	0.9494	1.6204
n(11.1m)	1.8893	1.4680	-
correlation	0.9619	0.6053	0.5958

Conclusion

We have carry on an substantial study of RSSI using the widely used TI CC2430 radio. Our experiments in outdoor and indoor environments have shown that the RSSI can provide information for deriving distance estimation and localization. Our experience experimental result demonstrate that RSSI is a feasible method in complex environment.

Keywords: Virtual Simulation, Earthquake Emergency Drill, Scenario Editor, Scenario System

Abstract. Earthquake is a small probability of unexpected events. Most of the emergency management personals did not experience the earthquake. They may cause flaws in the post-earthquake emergency response process, if they do not take part in earthquake emergency exercise. Traditional tabletop exercise, however, cannot provide a relatively realistic earthquake disaster scenes and vivid emergency background, so they need the virtual simulation exercises and drills for emergency management personnel to provide a real disaster site that is very similar to a drill. This paper presents system structure, function composition, scenario editing process of virtual reality simulation of earthquake emergency exercise and discusses a scenario editor based on OSG. Scenario Editor of earthquake emergency can control the drill and quickly rebuild the drill scene and improve emergency management personnel to design urban 3D scenes and earthquake and secondary disasters events.

Introduction

Earthquake is a small probability of unexpected events. Most of emergency managers do not have experience of the earthquake. They may cause flaws in the post-earthquake emergency response process, if they do not take part in earthquake emergency exercise. Traditional tabletop exercise does not provide realistic disaster scenes and vivid emergency backgrounds. Simulation of earthquake emergency response exercises can provide a relatively realistic virtual three dimensional earthquake scene, through numerical simulation of earthquake and secondary disasters and conduct simulation digital simulation, simulating real situations in which the maximum in the virtual space, development process, as well as the possible responses in disaster environments. The trainee can be immersed in this virtual earthquake disaster scene, discussion and deduction emergency decision-making and on-site disposal process, thereby enhancing the training staff ' feeling, promote relevant personnel to master the emergency plan prescribed duties and procedures, improve emergency command decision and coordination ability.

Virtual simulation scenario concept [1] extended from traditional military training exercise scenario concept, is the traditional military thinking to further expand. Virtual simulation scenario includes both traditional military scenario exercise background, exercise process, content description also includes a pair of visual simulation system and simulation end condition description. Earthquake emergency response exercises virtual simulation scenario is for earthquake emergency exercise, exercise virtual simulation system for earthquake emergency response required space, time, and in order to achieve the required background, conditions, constraints, rules and the simulation resource set.

Domestic and foreign researchers in the field of virtual simulation to sudden events made much research. Such as the United States of America ETC company ADMS for city emergency management at all levels and departments command personnel in key action planning, resource management, emergency response capacity assessment and cooperating with many departments in response to training provides practical experience. The national earthquake emergency rescue training base for the development of earthquake rescue virtual simulation scenario system can construct macro earthquake disaster scenario, earthquake rescue scene, and one-man operation ruins

scene of different resolution virtual training scene [2], can meet the earthquake rescue virtual simulation and training needs.

In this paper, we design virtual simulation scenario according to the earthquake emergency exercise platform on virtual simulation scenario generation system needs. The system is based on OSG (Open Scene Graph) for rendering platform, using XML as the structure of scene description language an application in virtual simulation scenario editor of earthquake emergency exercise. It provides visual manner, support a variety of customized training City and emergency practice content, including virtual earthquake disaster scene size, location and range of secondary disasters, victims of the position and number of tasks and goals. In this paper the design of simulation scenario system and emergency exercise system independent, without requiring the user to modify the program code to set of exercise. When adding new training task, users only need to modify by visualization of the exercise to exercise platform, without the need to modify other functional module.

Structure of scenario system

Concept scenarios edit system. Concept scenario edit subsystem is responsible for the scenario concept model development, it does not relate to a specific entity model. It is based on the emergency drill field uniform concept description library. It includes descriptions of entities, aggregation entities and processes and other elements of the concept of information, the information to be able to identify and describe these elements may state, tasks, events, behavior and performance, parameters and attributes etc.. Concept scenario model is to establish the relationship of elements, constraints, assigned tasks etc. It described include: scenario model hierarchy, synthetic natural environment description, drill entity and configuration, entity relationship, a collection of tasks and so on. Concept scenario model not only need a unified concept description for the foundation, but also used by the environment editor for generating synthetic natural environment data. Concept scenario modeling supported the scenario model of hierarchical, support collaborative modeling process, supported the scenario model coupling, in order to meet the development of large-scale scenarios.

Simulation scenarios edit system. Simulation scenario editor system is responsible for management and the establishment of simulation scenario. Simulation scenario is mainly considered simulation model resource mapping. Scenario concept model into the simulation scenario editor system, add the necessary information, into a simulation scenario model. Mappings include model mapping, model parameter mapping, mapping task of mapping, etc. Simulation scenario modeling process absorbed the concept scenario modeling features, and provides to the user a modified to function, the user can not only on the original concept to be mapped, but also on the scenario model two, add, delete, modify modeling original scenario model, and allows the user to build this directly simulation scenario. Simulation scenario editor subsystem is divided into to input module, scenario data rendering module, to cut and a reconstruction module.

Three-dimensional scenarios database. Three dimensional data is the base of simulation. Scenario database storage " three-dimensional " scenario, not only for the user study provides three-dimensional exercise scene scenario, but also embodied the staff, resources, command and control, exercise process in time, space constraints, but also easy to make and reconstruction. Three dimensional scenario databases include scenario database, standard alias called database, and model database. Scenario database save scenario description file and corresponding attachments contains information about the scenario 3D environment description, scenario basic assumptions, task scenario content. The rules database is to make the general and reusable, for trying to develop a set of specification language. Three dimensional scenario database models is the main earthquake disaster scene, emergency equipment, a character of visual physical model and its related parameter, function, behavior, audio description. Training evaluation database for virtual simulation effect, operators and agents or operation would be within the scope of assessment, to make emergency managers to better understand the scenario execution or inspection training effect.

Scenario operation management subsystem. Scenario operation management subsystem is responsible for the scenario query, maintenance, and to organize and control the process to run. Based

on the scenario of various data tables, model base and process parameter management data interpretation, real-time generation scenario 3D virtual environment, and the corresponding control parameter or parameters obtained from the interface module data real-time modification of the corresponding 3D virtual environment or to content and modify the corresponding database files, has to achieve constant operation of the process control and scenario database content modification. It contains three parts: like the retrieval module, to set the process management module, scenario database management and maintenance. [4]

Interface. Interface subsystem provides interactive interface between 3D scene and simulation application system. Interface subsystem is the communicate bridge between scenario subsystem and each simulation subsystem. It realizes the scenario parameters simulation data and corresponding data between conversion and exchange, which is mainly divided into man-machine interface and simulation application system interface.

Function composition of Earthquake exercise scenario editor

In this paper, scenario generation system is independent of earthquake emergency exercise simulation. Scenario generation system separate into scenario and simulation phase, keeps the scenario data independence, to make a set of input, storage and processing independently of the simulation based on typical cases, allowed to cut and reconstruction, promote scenario, simulation model and Simulation of the reusable member. The system is based on OSG (Open Scene Graph) for rendering core, taking XML as the structure of scene description language[5], operating system using Windows7. The function of the system mainly includes walkthrough city 3D environment scenario and earthquake and secondary disaster scenario.

Scenario of exercise city environment. Scenario of exercise city 3D environment mainly editing basic city scene, with emphasis given to the embodiment of scene in the terrain display and combinatorial logic, including city factors, social environment, the type of terrain complexity, road, climatic conditions, for a scene in one entity, can drag the mouse to a certain position, and can be directly input latitude and longitude position, the entity is automatically moved to this location. It includes not only a realistic topography and surface cultural characteristics of the terrain, but also can reflect all kinds of natural scenes and climate phenomena, such as water, trees, sky, rain, snow, fog. [6] At the same time the terrain environment also includes a number of 3D models, these models can be divided into static model and dynamic model. Static solid model refers to the ground some cultural characteristics such as buildings, trees, etc.; dynamic model refers to a variety of simulation entity model such as cars, pedestrians, such as a river[7].

Fig.1 The demo of exercise scenario

Scenario of earthquake disaster and second disaster. The system according to the levels of seismic hazard index and influence range, were used to build the four earthquake disaster events (especially major earthquake disaster, major earthquake disaster, earthquake disaster, generally larger earthquake disaster), each seismic disaster events influence field can and 3D virtual medium city model, 3D virtual city model small overlay display, display different city types at different magnitudes of city disaster damage, virtual city scene can pre-disaster contrast display and related city data comparison, match the seismic process demonstration, in the visual and sensory on trainees caused the most close to the real disaster shock effect, deepen the emergency management of earthquake disaster cognition degree[8].

The system can be set in accordance with the prior to the basic parameters of the earthquake data simulation of city buildings and infrastructure of the city disaster situation, provide different levels a

range of buildings, lifeline engineering damage status and distribution, direct economic loss, the casualties and homeless numerical and spatial distribution.

In the earthquake disaster scenario simulation basis, choose a dam height, hydrological, spillway, depressions distribution and upstream reservoir earthquake induced flood information, simulation of flood range model, by using the scene provides a three-dimensional reality and spatial analysis function, simulation of flood embankment somewhere once burst, flooding break into the city along the urban, flood submerged area, the submerged city of three-dimensional landscape and city infrastructure damage.

Scenario of second disaster fire is achieved by processing the input information, modeling, analysis and result output simulation link, through the qualitative model of fire scene simulation display and data description. According to different height of building structure, materials, construction of buildings, covering fire scene model, scene of each model are maintained in a predetermined scene database, through scripting and event information into a call and display[9], as shown in figure 3.

Fig2. Scenario of earthquake secondary fire

Earthquake secondary geological disaster scene model can describe in detail the disaster of topographic and geomorphic features, such as the slope of the terrain, length, size, shape, area of slope geological composition, gully characteristics and vegetation characteristics, while the use of 3D remote sensing image, describe the geological disaster type, location, boundary, size, activity mode, steady state, and show their on the surrounding environment and personnel activity areas of influence degree.

Before exercise, the director control group members can be dynamically constructed virtual 3D city and choose a different damage degree of buildings, the delineation of different secondary disaster distribution range, and the specific exercise add corresponding trigger events and set event influence scope, in order to drill the trigger operation. A virtual disaster scene through three-dimensional, all-round display of an emergency, disaster on city scene effects and damage degree, the influence scope and landforms, construction, population, traffic and other virtual situations, and support for dynamic adjustment of disaster information.

Earthquake emergency response exercises virtual simulation scenario system may wish to set already in the database to be indexed, and provides two ways to establish the scenario. System editor four typical scenario templates(Wenchuan city earthquake,Bachu-Jiashi city earthquake, Xingtai city earthquake, Liyang city earthquake) to deposit into a case file. On one hand, in the template based on modified, cut. In the edit new to timing, just out of similar scenario template was modified, which can avoid repeated input, shorten the scenario editing time, improve work efficiency. On the other hand is to edit a new scenario.

Fig3. Scenario interface

The system renders script data to speech, music, color, graphics, 3D model, with OSG as rendering platform, and build 3D virtual reality scenes, giving a good human-computer interaction interface to meet in various contexts exercise deduction need.

Conclusion

Earthquake emergency exercise is an important application domain of virtual simulation. Virtual simulation scenario of earthquake emergency response exercises provides a real disaster scene which is very similar to the exercise environment for emergency management personnel to carry out earthquake emergency exercise. In this paper, the realization of a desktop earthquake emergency exercise meet requirements of the virtual simulation scenario editor system for earthquake drill needs, and apply to the actual earthquake emergency drill. The system can be repeated fast reconstruction drilling scene, improve managing groups of drill city 3D scene scenario and earthquake and secondary disaster scenario. However, how to design the structure more reasonable, realistic rendering, interactive processing and deducing the rationality are in need of further study. In the later work constantly improve, in order to make the system better adapted to the earthquake emergency exercise of simulation system requirements. [10]

Keywords: P2P, Streaming media, Hierarchical, Adaptive

Abstract. P2P live streaming is a hot research topic of Internet, but for the defective of system architecture and scheduling policy, P2P streaming applications have poor user experience, such as long start-delay, long play-delay, and low play-continuity and so on. Firstly, based on the analysis of the advantages and disadvantages of previous works, this paper designed and implemented a hierarchical P2P streaming system. The system is composed by three layers: source management servers, region management servers, and peers. The underlying P2P overlay network is organized through Mesh-pull mechanism. We propose a new scheduling strategy to utilize the capacity of the peer. The new adaptive scheduling strategy considers the urgency and scarcity of the data blocks, and selects the appropriate neighbor nodes by monitoring neighbor nodes' the maximum load. The study of a real-life system provides valuable insights for the future development of P2P live streaming systems.

Introduction

In recent years, with the increasing demand for streaming application, peer-to-peer (P2P) techniques have been studied and deployed in live streaming systems. P2P techniques play a leading role in the Internet and are widely applied to many multimedia applications, such as PPStream [1], PPLive [2], QQLive [3]. P2P technique has the higher continuity with lower deployment overhead because it fully utilizes the upload bandwidth of other clients to reduce the server's bandwidth cost. Unfortunately, it adds more challenges including the playback continuity, the startup time, and suitable peering and scheduling strategies.

In a real-time application, the source server generates a live streaming which is divided into chunks with fixed size and some latest chunks are cached in the local buffer. All the clients can exchange the chunks with a small subset among the participating peers. Peers involved in these systems have heterogeneous uploading bandwidth capabilities while the average uploading bandwidth capability of the participating peers constrains the maximum service rate of the video stream that can be delivered successfully to all peers [4]. Accordingly, peers deployed in these live streaming systems need to receive a video stream with a service rate close to the average upload bandwidth of the neighbor peers with small delay.

In the P2P live streaming service, the video stream is diffused by the topologic overlay that constituted by these nodes which join in the distributed streaming system. The live stream is spreading in the network through the scheduler in every node. Peers connect each other and select some as its neighbors. Then each node will maintain a list of neighbors. The scheduler in a peer is running to exchange chunks with other peers. In the precious work, the content retrieval is based on three steps at each hop: Swapping buffer bitmaps with neighbors, analyzing and requesting content and finally sending data block [5]. Peers select neighbors based on a quantity of chunks which the neighbor sends to peer in every certain period. In a precious work [6], we indicated that constructing a good topology is a necessary way to minimize the playback delay. This paper will propose a peering strategy to reduce the difference of the video quality of peers and react quickly enough to the dynamic behavior of the participating peers and the fluctuation of underlying network. The main research

direction of P2P streaming is overlay organization. Numerous related strategies are proposed to optimize the overlay topology [7][8].

In this paper, we conduct a hierarchical P2P live streaming system. The rest of this paper is organized as follows. Section Ⅱ describes the design principle of the architecture and the detailed design of each module. Section Ⅲ proposes a new scheduling policy of the Mesh-pull mechanism P2P streaming media system and summarizes the advantages and disadvantages of other strategies [9-12], putting forward the optimization scheme, and applying to the Hippo system. In Section Ⅳ, Real-life measurement data were collected from the deployed live streaming system. We analyze the different scheduling strategies by the collected data. Finally, we discuss related work and conclusions.

Ⅱ Hierarchical P2P Live Streaming System

A. Major Components Of The System

This paper presents a hierarchical P2P live streaming system—Hippo. The system supports large-scale applications and multifunction (live, download) P2P streaming system. In this section, we first briefly introduce some terms.

SM (Source Manager): responsible for the entire network resources scheduling and querying. **RM (Region Manager)**: responsible for the scheduling of some a certain media resource and node. **Peer**: a kind of node, it a peer entities in P2P networks, including Speer and Dpeer. **Speer (Static Peer)**: a static node deployed as data source in the system. It's always online once launched. **Dpeer (Dynamic Peer)**: the user node, the state of this kind of node will follow the users' action. **Admin**: Provide the administration on the system and the management of resource scheduling. **LiveSvr**: the live server, responsible for the data downloading, packaging, identifying, and distribution to Speer. **LogSvr**: the log server, record the key log for issue tracking and data mining. **Segment**: media is cut to some piece according to a certain size; every piece of it is called a segment. They have the same size except the last one. **Block:** cutting the resources on the basis of segment, each called block. The size of it is fixed; the last one will be filled with empty content.

B. The framework of Hippo

The framework of Hippo including SM, RM, Speer and Dpeer, they form hierarchical service architecture, as shown in the Figure 1:

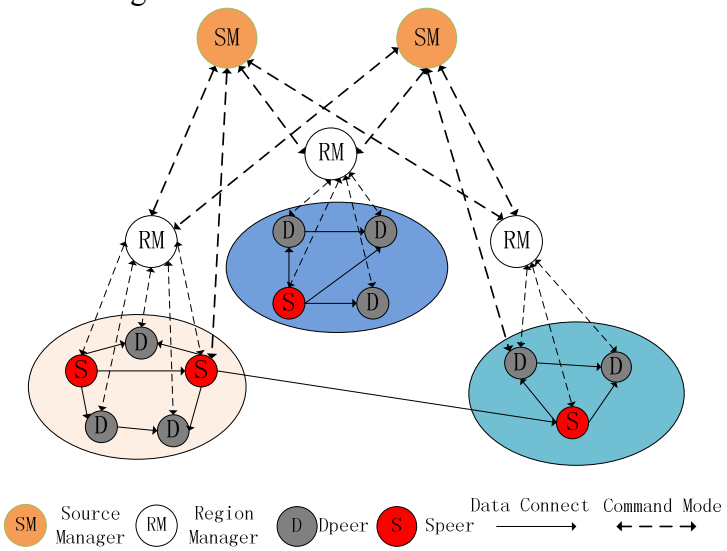

Fig.1. Hierarchical P2P architecture

SM is located on the top. It's responsible for the managing schedule (online, offline and copy) and queries of the media resources in the entire network. A SM represents a content publisher. It is

independent between different issuer of SM. SM is only concerned with resource distribution in what areas and don't care about specific storage location of resources. SM also can provide resources query service.

RM is located in the middle tier, which is divided according to region. Each RM is responsible for the Scheduling management of all resources and nodes in the area. RM concerns not only which resources can be getting in a certain area, but also which node they distribute.

SM and RM are fully connected. For any resource management server SMi and any area management server RMj, SMi will set up an interactive channel with the RMj, RMj report the resource information within the jurisdiction of the SMi to SMj, and receive news resource scheduling from SMi. RM record all the node information in this area, and responsible for the node scheduling and retrieval. RM is equal and divided. There is no direct interaction between each other.

A lot of nodes located at the bottom, they are Speers and Dpeers. When nodes are online, they will report the resource information to the belonging RM, and send heartbeat packet to the RM in its whole life. Speer provides data service and the object is other Speer and Dpeer. Dpeer enjoys media services as well as servicing for other Dpeer at the same time.

Upper is a Mesh structure organized by Speers, there are two factors lead to this Mesh structure, the first is that Admin sends the resource scheduling command. The second is that RM will monitor resources heat and Speers' load balancing, which will decide the movement between Speers.

Ⅲ The Design of Priority-based Adaptive Scheduling Algorithm

The task of scheduling is to choose a suitable partner in h from partner nodes set H for each request block b in request block set B, and request b. Then process request block according to a certain order. From this perspective, we propose a priority-based adaptive scheduling algorithm (PBASA). We defined a request as ask for a particular piece of data. Assume that

$$B=\{b[i] \mid i=0,1,2,\ldots,n-1\},H=\{h[j] \mid j=0,1,2,\ldots,m-1\}$$

The number of request blocks in the system is n; Partner node collection contains m elements.
Define the following functions:
Φ: N->B, Φ (i) means the i-th block.
Ψ: B->H, Ψ (b[i]) means the partner b[i] should request.
ζ: N->B×H, ζ(i)=<Φ(i),Ψ(Φ(i))>, mean the i-th request if request from partner Ψ(Φ(i)) to block Φ(i).
This article briefly describes the order of the request, namely the choice of function Φ.

As is described above, the request order of greedy method arranged mainly based on the "urgency". The least copy priority arranges the order according to "scarcity", hybrid scheduling algorithm is a combination of greedy method and the least copy priority. We combines the greedy method and the least copy priority algorithm, take both "urgency" and "scarcity" into consideration, and set a priority p[i] for each block b[i], decide the request order of b[i] according to the priority. t[i] is the expected play time of i-th block, we use it to represent the "urgency" of the request block b[i], it's the sooner the urgency higher. d and M in the formula are fixed for the same file, so the urgency can be simplified as t[i] =b[i] – play.

The parameter α is between 0 and 1, when α equal to 1, the priority only reflects the request of scarcity; when α equal to 0, priority is only calculated according to urgency of the request block; when α is between 0 and 1, both the urgency and scarcity are considered in the priority.

$$p[i]=-\alpha \bullet t[i]+(1-\alpha)\bullet r[i] \qquad (1)$$

FBSA [14] unified set for each node limit of simultaneous requests, which for the presence of heterogeneous network and node heterogeneity P2P overlay network is unreasonable and cannot achieve truly adaptive. In this paper, we adopt a dynamic approach to monitor partner nodes' the maximum load max_req. The procedure of monitoring the entire partner nodes' max_req is shown in

Algorithm 1.

Algorithm 1 Dynamic adaptive monitoring partner node's the largest load max_req

```
Set(λ, μ)
For each partner node:
    Initial (max_req)
For each partner node:
    if  req_T0 − req_T1 ≥ λ  then
        max_req ++
    else
        if  req_T1 − req_T0 ≥ μ  then
            max_req - -
        end if
    end if
```

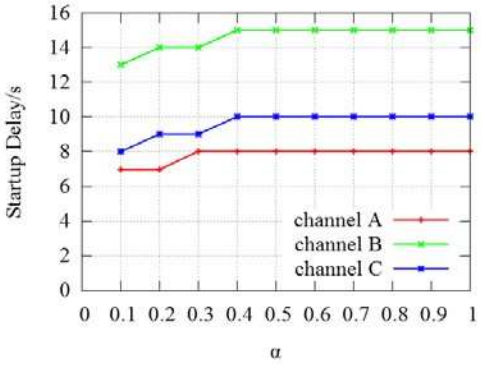
Ⅳ Measurement Results and Analysis

1. Experiment and Setup

Parameter	Value	Parameter	Value
SM	1	Speer Bandwidth	1 Gbps
RM	3	Dpeer Bandwidth	10 Mbps
Speer	6	Maximum neighbor	10
Dpeer	500	Channel A rate	5128 Kbps
Block Size	64KB	Channel B rate	2128 Kbps
Dpeer Buffer	200*64KB	Channel C rate	400 Kbps

2. *α* settings

We can see that α value range is [0, 1], and α values determines the influence of the "urgency" and "scarcity", combined the advantages of greed and RF. Greed has lower start-up delay and RF has better playback continuity and higher utilization rate of P2P, the following will determine the value of α from these three indicators.



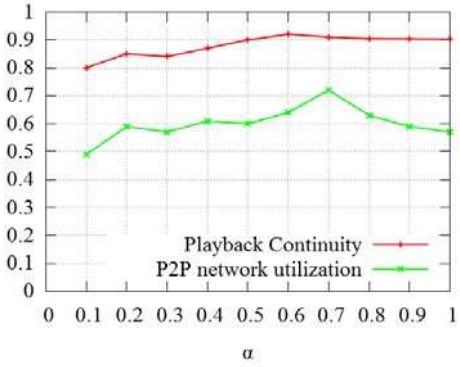


Fig.2. Alpha Setting Fig.3. Playback continuity and network utilization of Channel B

3. Performance Comparison Of Different Strategies

We can see from Figure 2, the higher the code rate is the higher the start-up delay. This is due to the higher code rate the larger data flow is. Start-up delay is smaller, along with the change of alpha, when α≥0.3, start-up delay is similar. This is because of the retransmission mechanism; the block in retransmission interval is first downloaded from Speer, which reduces the start-up delay.

This article use the definition of playback continuity in citation [13], which is the "persisted time/full time (including the pause time)"and defines the P2P network utilization as "blocks number downloaded from Dpeer/Total download blocks". Figure 3 is the experimental results of channel B, we can see that network utilization is better when alpha=0.7, and when alpha is 0.7 or higher, P2P utilization began to decline because of the retransmission mechanism. This article set the alpha value to 0.7.

It can be seen from Figure 4, PBASA algorithm has great advantage start-up delay compared with FBSA [14], and also has the advantage compared with MIX [15], reflect the flexible of combination of greed and RF. In the aspect of sustainability, we get the result in Figure 5, based on the experiment statistics of channel B. PBASA playback continuity remain at around 0.99 and has a less volatile, Mix algorithm remain above 0.9, and FBSA has a bigger volatility, the continuity is sometimes less than 0.9.

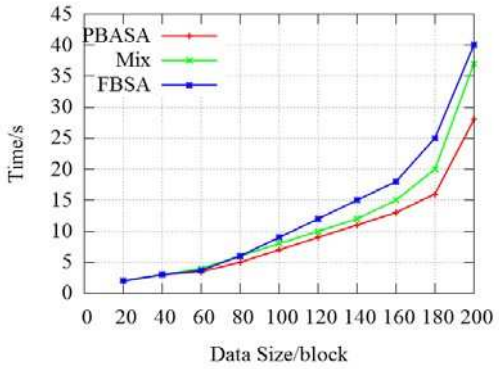

Fig.4. Start-up delay of different Scheduling Strategies

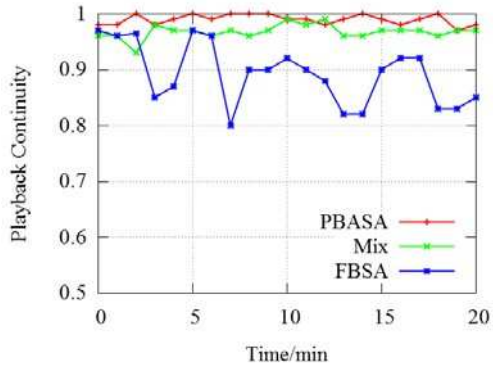

Fig.5. Playback continuity of different Scheduling Strategies

After comparing and analyzing the P2P network utilization in different scheduling algorithm using 3 different test channels, result is shown in Figure 6. For channel C with a low bit rate, Mix and PBASA showed a higher P2P network utilization (greater than or equal to 80%). Along with the rising of the bit rate, three kinds of algorithm of a P2P network utilization ratio become lower, but reduction of PBASA is minimum. It's easy to say PBASA has a better adaptability to different bit rate. Overall, PBASA reflects the higher utilization rate of P2P network.

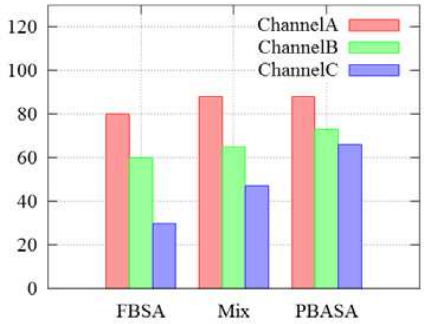

Fig.6. Comparison of network utilization

Summary

P2P live streaming system is an up and coming for the internet. Significant amount of research has been conducted in assessing the viability of peer-to-peer live video streaming, and some encouraging results have been reported. However, most of these systems have been tested only in research environments, and the deployment experience of these applications is very limited. In this paper, we design and implement a real-life hierarchical P2P streaming media system Hippo. It has three layers including SM (top), RM (middle) and Peer (bottom). We make a thorough research at live scheduling strategy and then present an adaptive scheduling optimization algorithm. In the end, we demonstrate the advantages of improved algorithm through experiments.

Keywords: Software Requirement, Secondary Development, Requirement Process, Requirement Management Tools.

Abstract. Requirement change is always a serious problem for developers and Software companies. Especially in putting ERP software into effect or ERP software secondary development, the requirement change has brought great disaster. The requirement process is not in-depth understanding and having no standard management mechanism are the main reasons for requirement changes. For ERP software companies, they must pay more attention to the requirement process and requirement changes.

Introduction

The ERP software which each company used to manage its resource nowadays is composed with standard product and secondary development. Standard product is the software that developed for common use. Secondary development is developed for satisfying the individual requirement of each company, Different from the all-developed-software.

The process of the secondary development exist a obvious problem. Before we develop the software, we must find out the requirement firstly. Not all these requirements can be solved by the standard product. We should develop the secondary development software to solve the other requirements. The requirements we finding out are changed frequently. The influence of the change is huge for the ERP software company and the client company. For ERP company, requirement changes lead to more expanding workload, project postponed, cost inflation, bad maintainability, and so on. In lifecycle of the software, the later requirement changes appeared, the more charge we cost (Table 1). If we find out the requirement changes early, we will save the cost.

Table 1. Restore cost of the Software lifecycle

Moment	Restore Cost
Requirement Moment	0.1~0.2
Design Moment	0.5
Coding Moment	1
Cell Test Moment	2
Thermoscope Test Moment	5
Maintenance Moment	20

There are many reasons results in the changes: an insufficiency of investigate, half_baked requirement understanding, disaccord requirement understanding, increasing of the users' requirement, changes of users' operation, changes of users' management system, and otherwise. These reasons can be carved up to two parts: one part is avoidable changes, the other part is unavoidable changes. In order to saving cost and enhancing the efficiency, we must put an end to avoidable changes and decrease unavoidable changes.

The process we capture and analyse the requirement is called “requirement process”. The requirement process is composed by requirement development and requirement management. (Fig.1)The requirement development is composed by problem capture, analysis, making standard explain and validate. The requirement management is composed by changes manage, edition manage, requirement slot and requirement estate slot.

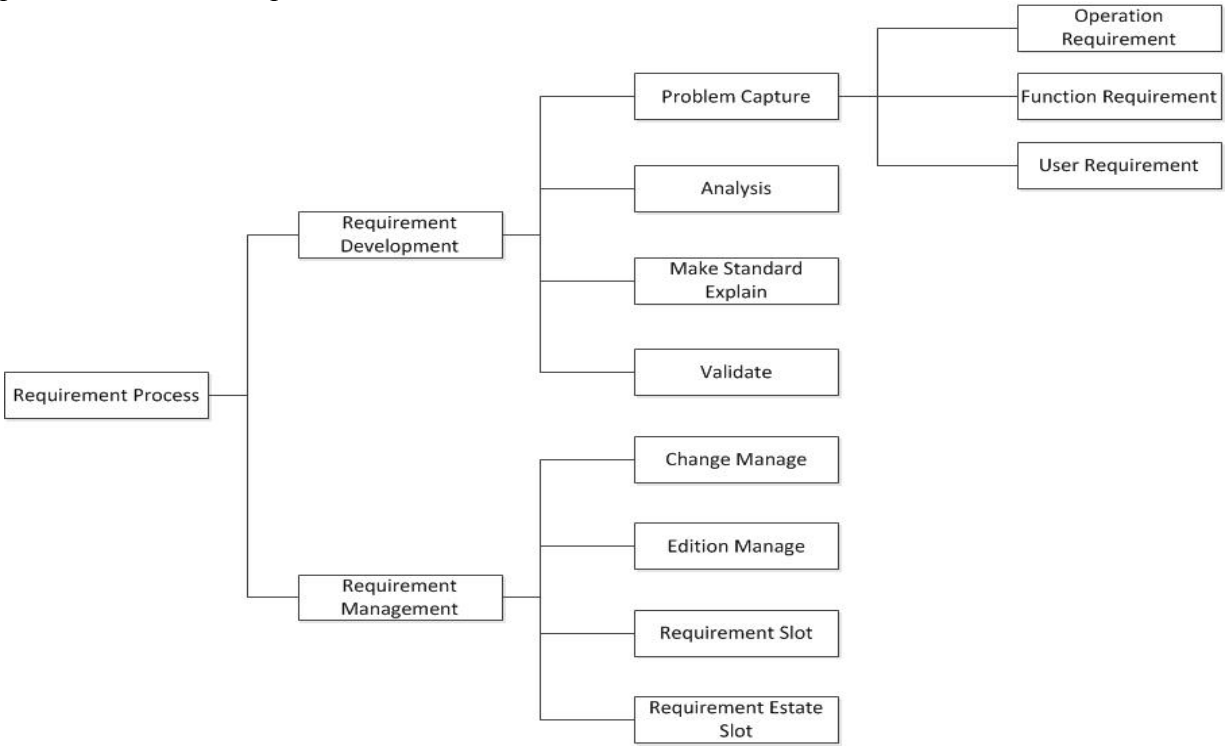

Figure 1. Requirement Process

ERP software second developers also use this requirement process as common software. Many ERP software second developers make a point of capturing problem in the requirement process. The problems include operation requirement, function requirement and user requirement. Operation requirement is the requirement of the aim that the client or the company wanted. This kind of the requirement is shown in item view and system bound documents. User requirement describe that users make use of the ERP system to accomplish the work and the task. This kind of the requirement is shown in user case. Function requirement define the software function that the developers must make it true. This kind of requirement make users can operate the ERP software. Because the ERP software is used to manage the enterprise resource, the developers pay much attention to the operation flows, the way of management, the ideology of management and the demand of the terminal users.

But ERP software second developers take no account of the analyse and other nodes of the requirement process. Analyse is an important node. In this node, developers first find out which requirement can be solved by standard product, which is not true of the ideology of management, which is disobedient to the modern logos of the requirement , finally which is must be developed by the developers. Then the developers analyse the requirement that need second develop with the requirement process. Nest nodes of the requirement process nodes are omitted. This nonstandard requirement process result in the frequently changes of ERP software project.

How to put an end to avoidable changes of ERP software? How to reduce unavoidable changes of ERP software?

The secondary developers or the ERP software companies should pay more attention to each node of the requirement process, Build a standardized system to control the requirement process. They also can use some requirement management tools. These requirement management tools divide into two parts. One is requirement content management tools, the other part is requirement process management tools. Requirement content management tools can manage the entry of the requirement,

follow up the requirement, manage the base line of the requirement. These tools include IBM DOORS, IBM Rational Requestpro, Borland CalibraRM, Hanskey Dragonfly, etc. Requirement process management tools mainly manage the requirement changes. These tools contain IBM Clearquest, Butterfly of Hanskey, IBM Change, etc.

Rational Requestpro, is a familiar requirement content management tool that manage the requirement and the use case. This tool is easy used and compositive. This tool expand its function with its integration. It can work with Rational software products. It can manage the requirement by making the requirement like the item. It also brings a lot of functions like information query, slot and management in the lifecycle of the software. With these functions, the tool can help us to evaluate the effect of the changes and manage the requirement changes. It also can recede the project risk.

IBM Rational DOORS, at one time called Telelogic DOORS. DOORS is a oldest company requirement management software. It can help the corporation to communicate effectively and enhance the collaboration by using DOORS/ERS. It can use different methods to manage different structures. That make the management process more crystal. It also can make the corporate out of the zone restrictions.

Borland CaliberRM, is a requirement define and manage tool that based on Web and collaboration. It is very helpful for distributed development team. It can raise the delivery schedule of the application system. CaliberRM gathered many developed tools: project planning tool, software configuration management tool, the analysis and design tool, object modeling tool and test management tool, etc. A collection of these tools can understand the requirement and the influence of the requirement changes better.

Besides these famous requirement management tools, the ERP companies can develop a little requirement management tool. This tool is faced to the secondary developers. By using these requirement management tools, we can control all the nodes of the requirement process and make all the requirement change process normative.

The first and the second node of the requirement process are the most important nodes in all of the nodes. If we want to put an end to avoidable changes of ERP software and to reduce unavoidable changes of ERP software thorough, we should pay more attention to the first two nodes: capture the problem and analysis.

Capture the problem is the requirement search process, the developers communicate with the client. Talking for the requirement of the ERP software. This process is the process of communication. For the customer psychology, their ideal state is coordinating with our research. But unfortunately, in the process of real research, customers are different. Many of them have unrealistic ideals, what they expect in ERP software is imaginary mode. The requirement cannot realize. Many of the customers present the requirement that not the operation and the flow path of the routine work. They are not the actual operator. Instead of the actual operator, they tell the requirement by their imagination and understand. Many of the customers have psychological conflict on enterprise informatization construction. They think that the ERP software may increase their workload. They also maybe don't want to change their mode of operation. Many of the customers shirk their responsibility when talk about the key point of the software process. They don't confirm the main flow path.

When the features above appeared, our developers should have good communication skills. We can take the following measures to solve the above features. Talking to the customers from different level and different department, because the people from different organization level , different business department and different computer level, have the different requirement. For example, the customers like general manager level maybe interested in macroscopic report, they have no suggestion on the details of operation. While the department managers may pay more attention on daily work report, the function of the system and the expansion of the function. Ordinary business operation personnel may interesting in the mode of operation, interface style and easy-to-use. So, group the customers becomes very valuable. We should talk to many customers ,then find out the difference between the description of the requirement from each customer. Finally we let the leader to

confirm the different requirement. We can make friend with the customers, this way can reduce the psychological reactance of the customers.

Summary

Requirement changes cost much resource of the ERP companies. To save the cost, the ERP corporation must pay more attention to the requirement process. The requirement process have many nodes. We can use requirement management tools to control the requirement process. Especially, the problem capture is the process of the communication. Developers should have the good communication skills. We hope the ERP secondary development may have a useful requirement management system. By using the system, we can reduce the requirement changes and finish the ERP project successfully.

The study on optimization of energy consumption for nodes ZigBee wireless sensor networks based on library information service

Zhang Junsong Sun Bao Liu Dongmei

North China Institute of Science and Technology,CHINA

Keywords: optimizing, node's dormancy ,quality of network communication

Abstract：This paper studies the key issues of how to reduce the energy consumption of the ZigBee nodes, through optimizing node's dormancy mechanism without affecting the quality of network communication.

1 The Introduction

Owing to the wireless sensor node is powered by battery, we need to consider the energy consumption of these nodes if many sensor nodes are decorated in the practical application.[1] If the energy consumption is small, we can use nodes at a long time without replacing battery; but if the power consumption is big, replacing numerous battery at a short time will increase human burden. Under this application background, this paper establishes an energy saving strategy, based on ZigBee wireless sensor network , which can accomplish timing measurement.

2 Zigbee technology application in library information service

ZigBee[2] technology is a new type of short distance wireless communication technology,and this technology is considered most likely to be used in industrial control occasions.And it also can use the 2.4 GHz frequency band for free.[3]

From the network configuration，there are three types of ZigBee network nodes: ZigBee coordinator nodes, ZigBee router nodes and ZigBee terminal nodes.[4]

Special attention should be paid that the specific architecture of the network will dramatically affect the resources required for equipment. ZigBee network main support three kinds of topology structure: the Star, Mesh and Cluster-Tree structure. In this several kinds of topology structure, the star network requires minimum resources.[5]

If the zigbee technology is applied to library information service, the library information designated collection will come true.The collection system generally use star network.

3 Full symmetric transmission model of competition for channel resources based on CSMA/CA algorithm (Model one)

In this article, model adopts star network, with the fixed device nodes distibuted in the scene。That is，the coordinator in the center, the surrounding is uniformly distributed with N terminal nodes .

In this model, node 1 to node N will upload the data, which is collected by themselves, to the coordinator within the prescribed period of time T.Because the position of each node is symmetrical and send data may happen at any time within the 0~T, there may be multiple nodes upload data at the same time . ZigBee protocol uses the CSMA/CA technology to solve the above problems.

Under the CSMA/CA algorithm of ZigBee protocol, when receiving the beacon frame, the node detects CCA idle channel before sending data. The node will send data if the channel is empty, otherwise the backoff counter randomly generates one number in 1~5, the number minus 1 after a time slot until it reduces to 0 ,then the next CCA detection begins. In the process of uploading data, node includes the states: CCA idle channel detection or retreat, data transmission, receiving the ACK response frame, successful transmission . State transition diagram is shown in Figure 1:

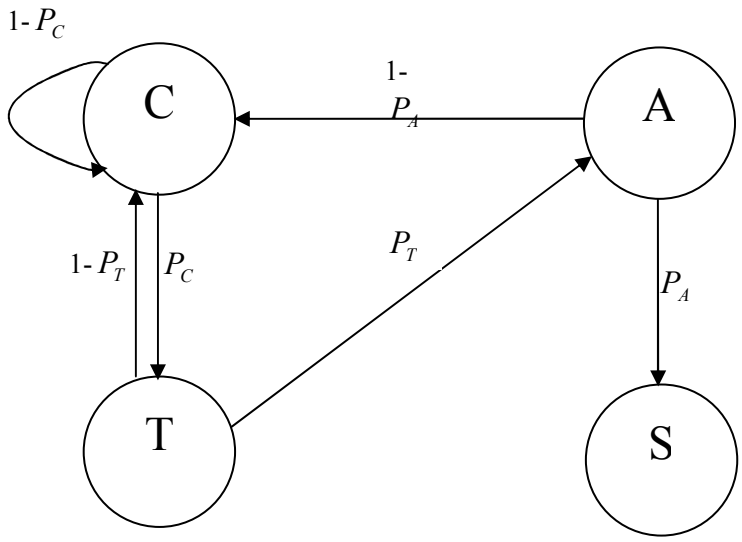

Figure1:State transition diagram of node in the process of uploading data

4 Communication as planned model based on CSMA/CA algorithm (Model two)

In this model, node is scheduled to communicate, every two nodes wake up successively, at the same time the two nodes'position is centrosymmetric, with the coordinator at the center.

State transition matrix of node 1 are as follows:

$$P_1 = \begin{array}{c} \\ C \\ T \\ A \\ S \end{array} \begin{array}{c} \begin{array}{cccc} C & T & A & S \end{array} \\ \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 1-P_T & 0 & P_T & 0 \\ 1-P_A & 0 & 0 & P_A \\ 0 & 0 & 0 & 1 \end{pmatrix} \end{array}$$

In the model one, the state transition matrix of any node is:

$$P = \begin{array}{c} \\ C \\ T \\ A \\ S \end{array} \begin{array}{c} \begin{array}{cccc} C & T & A & S \end{array} \\ \begin{pmatrix} 1-P_C & P_C & 0 & 0 \\ 1-P_T & 0 & P_T & 0 \\ 1-P_A & 0 & 0 & P_A \\ 0 & 0 & 0 & 1 \end{pmatrix} \end{array}$$

In this model system, the probability of any node grabs channel through the CCA is P_C. If the channel is busy, then the node will transfer to the retreat state with the probability of 1- P_C, and will wait for the next CCA detection until grabs the channel. Therefore, a node grabs channel based on the CSMA/CA algorithm so as to enter into the state of transmission state, which need $\frac{1}{P_C}$ times.

Expectations of power consumption in this process is: $\frac{1}{P_C} \times E_C$

N nodes' expectations of energy consumption in this process is : $N \times \frac{1}{P_C} \times E_C \times N$

Under the worst communication condition, in the N communication time, any node state transition matrix is :

$$P_N = \begin{array}{c} \\ C \\ T \\ A \\ S \end{array} \begin{array}{c} \begin{array}{cccc} C & T & A & S \end{array} \\ \begin{pmatrix} 1-P_{NC} & P_{NC} & 0 & 0 \\ 1-P_T & 0 & P_T & 0 \\ 1-P_A & 0 & 0 & P_A \\ 0 & 0 & 0 & 1 \end{pmatrix} \end{array}$$

Expectations of power consumption in this process is: $k \times \frac{1}{P_{NC}} \times E_C$

N nodes' expectations of energy consumption in this process is: $k \times N \times \frac{1}{P_{NC}} \times E_C \times N$

Under the same conditions, that is,the quality of communication channel is the same, comparing the model two and model one's power consumption is the same as the comparison of $\sum_{i=1}^{\frac{N}{2}} \frac{2i}{P_{2iC}} \times E_C$ and $N^2 \times \frac{1}{P_{NC}} \times E_C$.

In this paper, the model N is even. When N is an even number, $\sum_{i=1}^{\frac{N}{2}} \frac{2i}{P_{2iC}} < \sum_{i=1}^{N} \frac{i}{P_{iC}}$

As $P_{iC} \geq P_{NC}$, so $\sum_{i=1}^{N} \frac{i}{P_{iC}} \leq \sum_{i=1}^{N} \frac{i}{P_{NC}} = \frac{1}{P_{NC}} \times \sum_{i=1}^{N} i = \frac{1}{P_{NC}} \times \frac{(1+N) \times N}{2}$

As $N < N^2$, so $\frac{N^2+N}{2} < N^2$

The conclusion is as follows, $\frac{1}{P_{NC}} \times \frac{(1+N) \times N}{2} < \frac{1}{P_{NC}} \times N^2$

Under the good condition of communication channel quality, in model 2, each node can transfer the data in their own planning time N, therefore, the expectation of nodes' power consumption is: $2N \times E_C$

Under this condition,N nodes' expectations of energy consumption in model one has been computed: $N \times \frac{1}{P_C} \times E_C$

As $\frac{1}{P_C} \geq 1$, $N \geq 2$, so $N \times E_C < N^2 \times \frac{1}{P_C} \times E_C$

The above results simulation by matlab,as shown in figure 2:

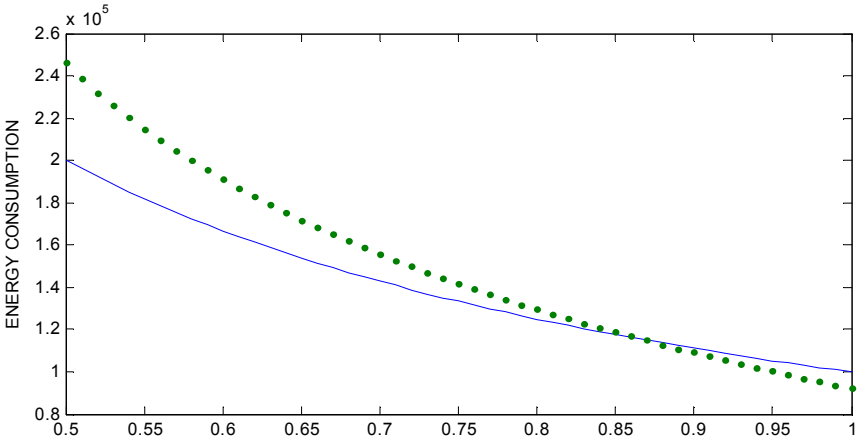

Figure 2:Comparison of energy consumption of the two kinds of model

In conclusion, under the same channel quality conditions, the power consumption of the entire network in model 2 is smaller than model 1 , which can achieve expected purpose——node optimization, reducing power consumption.

On the model analysis of wireless sensor networks based on library information service

Liu Dongmei Zhang Junsong

North China Institute of Science and Technology,CHINA

KeyWords：model analysis,wireless sensor networks,communication as planned

Abstract：In wireless sensor networks based on ZigBee,we often see such a model that full symmetric transmission model of competition for channel resources based on CSMA/CA algorithm. For the purpose of reducing the energy consumption of entire network,this paper establishes a model that communicate as planned which based on CSMA/CA algorithm.

1 The Introduction

With the rapid development and increasingly mature of communication technology, embedded computing technology and sensor technology,Micro Sensors, which has the perception, the computing power and communication ability,began to appear around the world.[1] This kind of sensor networks is made up of sensor technology, embedded computing technology, distributed information processing technology and communication technology, which can cooperation to real-time monitor, perceive and gather information of various environment or monitored objects in the network distribution area. They can process this detailed and accurate information and transmit the information to users in need.[2]

2 Zigbee technology application in library information service

ZigBee technology is a new type of short distance wireless communication technology,and this technology is considered most likely to be used in industrial control occasions.And it also can use the 2.4 GHz frequency band for free.[3]

From the network configuration,there are three types of ZigBee network nodes: ZigBee coordinator nodes, ZigBee router nodes and ZigBee terminal nodes.[4]

Special attention should be paid that the specific architecture of the network will dramatically affect the resources required for equipment.ZigBee network main support three kinds of topology structure: the Star, Mesh and Cluster-Tree structure. In this several kinds of topology structure, the star network requires minimum resources.[5]

If the zigbee technology is applied to library information service, the library information designated collection will come true.The collection system generally use star network.

3 Communication as planned model based on CSMA/CA algorithm

In this model, node is scheduled to communicate, every two nodes wake up successively, at the same time the two nodes'position is centrosymmetric, with the coordinator as the center. That is to say, the time T_X is assigned to each node,the centrosymmetric two nodes awaken, receiving beacon signal from the coordinator, and communicate with it, as all the other nodes in the sleep state. For example,a coordinator (node 0) and six nodes (node1 - node6) compose the star topology network,which are evenly distributed.Node 1 and 4 wake up at the same time and communicate with the coordinator , node into the sleep state after the communication; In the second T_X , node 2 and 5 wake up at the same time, receiving beacon signal from the coordinator, and communicate with it , as all the other nodes in the sleep state. After the node 2, 5 communicate with the coordinator , the two nodes enter the sleep state; When the third T_X coming , node 3 and 6 wake up, receiving the beacon signal from the coordinator , and communicate with it... and so on. In the period of time T_X , every node has k superframes, that is to say, each node in the allocated time

T_X has k chances to transmit data. Each superframe accounted for $1/k$ of the the entire time T_X. If the node transfers date successfully in the first superframe, it will in a dormant state in the rest of the k-1 superframes, no longer wake. If the node within its distribution time T_X transmit data unsuccessfully with the coordinator, then when the next node wake-up time arrival, the two nodes will compete for channel resources.

State transition matrix of node 1 are as follows:

$$\mathrm{P}_1 = \begin{array}{c} \\ C \\ T \\ A \\ S \end{array} \begin{array}{c} \begin{array}{cccc} C & T & A & S \end{array} \\ \begin{pmatrix} \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 1-P_T & 0 & P_T & 0 \\ 1-P_A & 0 & 0 & P_A \\ 0 & 0 & 0 & 1 \end{pmatrix} \end{array}$$

In the ideal situation, the product of the node's state at any moment and the state transition matrix is also the state.The state of node at any moment may be in CCA detection or retreat, data transmission, receiveing the ACK response frame, the data packet transferred successfully ,node comes into dormant state. The state of node at any moment is υ, according to the node state transition matrix of transport matrix P_1, calculating the ideal steady state transfer state:

Ideal steady state transfer status, namely:

$$\begin{pmatrix} \frac{1}{2} & 1-P_T & 1-P_A & 0 \\ \frac{1}{2} & 0 & 0 & 0 \\ 0 & P_T & 0 & 0 \\ 0 & 0 & P_A & 1 \end{pmatrix} \times \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix}$$

Calculating the ideal steady state transfer status is = (0,0,0,1). Therefore, successful dormancy is the absorbing state of the whole system. The energy consumption of the node in each state is written as .The initial state of node 1 is $\mu = (1, 0, 0, 0)$, that is to say, the node 1 can access channel after receiving the beacon frames, because there is no other nodes to compete. The allocation of node 1's transmission time divides into n time slots.,every once in a time slot, the power of the node can be calculated according to the state transition matrix in this state. That is,

$$\begin{aligned} &\mu \times \bar{E} \\ &\mu \times \mathrm{P} \times \bar{E} \\ &\mu \times \mathrm{P}^2 \times \bar{E} \\ &\cdots \\ &\mu \times \mathrm{P}^{n-1} \times \bar{E} \\ &\sum_{i=1}^{n} \mu \times \mathrm{p}^{i-1} \times \bar{E} \\ &= \sum_{i=1}^{n} [(\mu \times \mathrm{P}^{i-1} \times \bar{E} - \upsilon \times \bar{E}) + \upsilon \times \bar{E}] \\ &= \sum_{i=1}^{n} (\mu \times \mathrm{P}^{i-1} \times \bar{E} - \upsilon \times \bar{E}) + n \times \upsilon \times \bar{E} \end{aligned}$$

$$\left| \sum_{i=1}^{n} \mu \times \mathrm{P}^{i-1} \times \bar{E} - n \times \upsilon \times \bar{E} \right| = \left| \sum_{i=1}^{n} (\mu \times \mathrm{P}^{i-1} - \upsilon) \times \bar{E} \right| \le \sum_{i=1}^{n} e^{-C(i-1)} \| \bar{E} \| = \frac{1-e^{-C \times n}}{1-e^{-C}} \| \bar{E} \|$$

In this model, the communication time assigned to each node relative to the data transmission time is relatively long, through the steady state transition probability we can calculate that the successful dormancy is the absorbing state of the whole system. But the possibility of a node unsuccessful in its transmission data can not rule out within the allotted time, such as the channel quality is poor，may exist in this case. As the next node communication period, the case that four

nodes compete in the channel resources may exist. If four nodes transmit data at the same time data , the four nodes state transition matrix is:

$$\mathrm{P}_2 = \begin{array}{c} \\ C \\ T \\ A \\ S \end{array} \begin{array}{c} \begin{array}{cccc} C & T & A & S \end{array} \\ \begin{pmatrix} 1-P_{4C} & P_{4C} & 0 & 0 \\ 1-P_T & 0 & P_T & 0 \\ 1-P_A & 0 & 0 & P_A \\ 0 & 0 & 0 & 1 \end{pmatrix} \end{array}$$

According to the communication situation in the worst case, that is,in the last node's plan communication time data,all the nodes compete for the channel resources,the energy consumption under the condition of mathematical expectation is:

$$k \times （2 \times \frac{1}{P_{2C}} \times E_C + 4 \times \frac{1}{P_{3C}} \times E_C + \cdots + N \times \frac{1}{P_{NC}} \times E_C ） = \sum_{i=1}^{\frac{N}{2}} \frac{2i}{P_{2iC}} \times E_C \times k$$

4 Summary

This paper analyzes the wireless sensor network based on ZigBee. To reach the aim of reducing the energy consumption of entire network，this paper establishes a model that communicate as planned which based on CSMA/CA algorithm.

In the future,we will compare this model with the full symmetric transmission model of competition for channel resources based on CSMA/CA algorithm,to study the superiority of this model in terms of energy consumption of entire network.

Keywords: Cloud Platform; Integrated Management; IT Services

Abstract. Introducing the background of domestic park cloud platform. Comparing the Platform construction operations of Suzhou Software park, Hangzhou east software park, Beijing Zhongguan Village software park, Chengdu Tianfu software park and Dalian software park platform construction operation comparison. Through the study, we concluded that park's cloud platform was more than just an IT service platform. It was also a park assets and service of integrated management platform and learning and employment platform. Cloud platform will support park characteristic industry and provide information for the development of the park's industry.

Introduction

These years, under great support of governments at all levels, our country has been integrating regional software industry superiority. Not only does it create favorable hardware and software environment for hardware industry, but it does great contribution to establishing professional creative service system, talent strategy, medium-sized and small enterprises incubation, scale expansion and internationalization of software enterprises, financing and transforming traditional industry.

As IT applications deepen, the quantity of data is certain to increase day by day. Cloud computing, as a burgeoning commercial computing model, gives up a new inspiration [1-3].

Domestic famous parks speed up in building up cloud computing in the process of construction. It will not only improve comprehensive problem solving ability and enhance the orientation of service-providing park, but it can improve intelligence of park management.

The comparative analysis of famous park clouds' construction and operation

Suzhou industry park

These years, Suzhou Industry Park has been focusing on software, monolithic circuit, bio-pharmaceuticals, animations and games, NT, telecommunication of next generation under the aim of technology spanning plan and creating creative science and technology park. Also it creates support ability of industry development, improves self-dependent innovation ability of enterprises and promotes industry development environment. [4]

(1)Industry technology service platform

Surrounded by software, monolithic circuit, bio-pharmaceuticals, animations and games, NT and new materials, it has completed all coverage of key industries. It has established software rating public service platform, software as a service (SaaS) platform, monolithic circuit design and testing

platform, bio-pharmaceuticals experiment platform, antibody profession technology service platform, NT process platform, NT detection platform and animations and games public technology service platform. Also it will lay out to integrate telecommunication industry service platform, embedded software platform, biological new drugs security rating platform, GMP platform, NT photoelectron and NT manufacturing technology platform.

(2)Supporting service platforms

Centering on science and technology innovation, science and technology innovation integrated service center is set up. It integrates Suzhou Industry Park enterprises, colleges and universities within district, Suzhou NT institute, intermediaries at the aim of professionalization, marketization, socialization service. Also a integrated service platform is built up, covering investing and financing of science and technology, industry-university-research cooperation, technology achievement transformation, scientific information and information services, project application service, policy consulting, market channels and promotion, intellectual property, talent training, integrated supporting and so on.

Hangzhou east software park

The east software park has been exploring a sustainable development mode in its developing process, which can help the park of science and technology develop successfully. From the point of this strategy's aim, it puts forward 2 requests, which can be describe below: one is to solve the problem of how to achieve low carbon, high effective, sustainable development; the other is the growing problems of medium-sized and small enterprises. It's construction centering on new service system of scientific innovation, which will quicken the development of science and technology industry.

The service contents from wisdom park cloud platform mainly include 5 aspects. The first one is flexible computing cloud, flexible computing service based on Ali cloud. The second one is testing cloud, which can simulate real users' operation and conduct real time function tests so that the cost pressure of enterprises will be reduced. Thirdly, developing cloud includes integrated circuit and software developing collaboration platform. ALL sorts of public technology platforms co-build developing environment to help medium-sized and small enterprises grow quickly. Fourthly, cloud official business can provide cloud desk renting service, which is safer, more reliable, easy to manage and quickly arranged, extensible. The enterprises don't need to apply resources to operation and maintenance of desk system. So it improves IT efficiency and reduces TCO. The fifth one is application of web of things. The management system based on web of things in wisdom park arranges and achieves resources management, intellectual lighting, intellectual air-conditioner, equipment inspecting.

Beijing Zhongguancun software park

Zhongguancun software park service cloud was officially released online in 2011 cloud world conference. The platform serves more than 50 enterprises in Zhongguancun software park with Iaas service (cloud server, cloud storage), SAAS (CRM, e-mail system, online network disk), basic PAAS service and so on. As Xiangyun project and the first arrival industry park cloud service platform in domestic, it insists on the idea of "the government guides strategically, the professional companies operate, leading enterprises drive, public platforms support". It gathers core enterprises

from every link of industry chain and establishes \industry innovation eco-system, which will play an important role in setting new standards, new industry condition incubation and cultivation of new leading enterprises. [5]

As the first park cloud service platform with independent intellectual property rights in domestic, now Zhongguancun cloud service platform has achieved flexible computing and storage with webs which is typical IaaS service ability. What's not the same implementation model with foreign public clouds such as Amazon is that Zhongguancun cloud service platform achieves arrangements of end to end and localization delivery. And it gets support from distributed visualized data center of China Netcom broadband MAN at the same time. So it solves thoroughly the problems which domestic cloud service delivery quality can not be guaranteed such as cloud service's availability, reliability and safety.

Chengdu Tianfu Software Park

At present, Chengdu is managing to create the wisdom and modern garden city of the world. Smart City will be an important direction of the city's development when the city develops economy and information technology. As China's largest professional software park, Chengdu Tianfu Software Park is also accelerating the pace of constructing smart park. Information construction is the carrier. The manager will strive to connect resources within the park with external resources. New a park one-card-through system and Chengdu Tianfu card is integrated. User can own e multifunction card and combine other redundant cards [6].

"Network E-School" established by Tianfu Software Park is a new online learning platform. It uses professional courses of world-renowned education services provider in order to provide an interactive and new "E-learning" training model for all businesses online in park. Tianfu Software Park also offers a number of public platform resources to enterprises. Among them, the moat famous is national public platform software technology resources spend billion to build. The managers can rent a variety of development equipment and software after enterprise applications are put forward. For entrepreneur teams and the developing enterprises, such platforms will largely reduce development costs on businesses.

Dalian Software Park

Dalian Software Park is a service-oriented company that manage science and technology, real estate and park management services. Service system includes investment development, project management, investment management, customer service, property management and human resource services . The departments of investment development and project management are body of work in Dalian Software Park. They are responsible for the park's construction planning and project management services on site. Most department personnel are represented the number of company staff.

Dalian Software Park is not involved in the construction of smart metering systems and smart card system. The managers use Kingdee system to integrate internal company information. The system belongs to the ERP system. It mainly has the finance function and CRM management functions. It covers a single function that involves the projects, finance, procurement, CRM, and part of the company management process. There is no professional team to construct and maintain the information systems. They use professional systems such as human resources service platform and campus portal to provide relevant information about the park's corporate information system.

Summary

Cloud platform is established in order to improve efficiency and reduce costs. In this context, the integration of resources and building of public service platform is extremely important. Through cloud solutions, physical separation can be realized just in logic [7]. Also through virtualization, we can make a substantial increase in efficiency. Therefore, we can reduce a lot costs of operation, hardware software, and so on.

Through comparing the construction and operation of the domestic famous park platform, we know cloud platforms could be able to manage park resources. In the development process, the platform can learn management experience. Based on the principle called "resource sharing, business cooperation, complementary advantages, value-added innovation and sustainable development", we can achieve the goals that integrating public service resources, configuring and scheduling uniformly and building intelligence platform. Park's cloud platform is not only an IT services platform, but also a comprehensive platform that manages park's assets and services. We can learn and find jobs on the platform. The cloud platform would be a support platform that has characteristic industry. It will provide strong support for the development of the information industry park [8-9].

Keywords: Agenda setting; micro-blogging; information resources; local image

Abstract. This article studies the characteristics of agenda setting and mode of transmission, which are presented in the micro-blog information resources in spreading the local image. Discovers the operation pattern, at the same time, tries to seek the common pattern of local image communication in new media times through micro blogging, which on behalf of the local social media, and then use the micro-blog information resources to shape and optimize the local image.

Traditionally, people always do research on the information resources sharing from two aspects: one is to consider information resources from the rational distribution and configuration in the geographic area to achieve maximum sharing; the other is to share information resources through cooperation between the information providers [1]. Micro-blogging is a derivative of personal blog. It is a We-Media form, “Users can send short messages with maximum 140 words to their micro-blog through cellphone, IM(such as QQ, MSN, Gtalk, etc.), email and web”[2]. These short expressions might be catharsis, inspiration catching, just forward something, or self-entertainment, are all shown in public. It is clearly that to disseminate the micro-blogging information, the geographic area has merely no influence on the micro-blogging information resource flows. But “the cooperation between information providers” is more prominent in the micro-blogging information, which carries out mass information and has characteristics of interpersonal communication. With the popularization of 3G technology, tablet PC and other clients have become the popular platform for publishing micro-blogging information. Micro-blogging information is the very influential information resources on the public. Its’ agenda setting function is highlighted in disseminating local image in public place, and has further development Political scientists, Bernard Cohen, stated in the book, The newspaper and foreign policy, that “the press may not be successful much of the time in telling people what to think, but it is stunningly successful in telling its readers what to think about”. In the 1968 presidential elections study, by comparing “what the voters thought was the most important election issue” and “what the Media reported was the most important issue in the same period”, American Communication experts Maxwell McCombs and Donald Shaw found a strong correlation between them. In 1972, they first put forward the agenda-setting function of mass media in The Agenda Setting Function of Mass Media. They believed that “news reports by the Media and information convey activities influence the salience of topics on the variety of public agenda, affects the judgment of people around the world to the 'event' and the degree of its importance”. This theory also stresses that agenda setting is the media’s ability to transfer salience issues through their news agenda so the public agenda can form their understanding of the salience issues [3]. Agenda setting means that the media, an institution engaged in “environment reconstitute”, is not only the important information source, but also the important impact source. In micro-blogging information resource dissemination, the increase of communication subject let every micro-blogging users become information receiver, commenter and transmitter. The decentralized the speaking rights make micro-blogging users having the same potential audience the traditional media has and build a community of discourse focus with the traditional media and Internet media (in other application form). Therefore, compared with the

traditional agenda-setting theory, micro-blogging information resources agenda-setting has widen its scope, and could achieve through the interaction between the institutional or personal micro-blogging and user.

(1) Institution Micro-blogging Information Resource Sharing

At the early stage of blog, the representative of the We-Media, blog website usually made judgment of what topic the public might be interested based on the news event happened recently, and took the active planning way to arrange, recommend or post the context published by blogger, or set some discussion topics on the webpage to let the user participate in topics through blog context, and these blog context often get higher clicking rate and reading rate because of edit settings to set the agenda of the role. The 2006 year China's blog survey report published by China Internet Network Information Center (CNNIC) showed that over 40% readers read blog through the blog home page [4]. This creates a blog channel editor for the audience agenda setting， and this agenda setting dominated by web site and agency blog still work in nowadays.

The appearance of "micro-blogging square" [5] displaces the original agenda-setting function of the blog portal. But this function is been diluted in a certain extent because of the limitation on word amount, and replaced by the information released by every institution and media's micro-blog. For local image, these institutions do a micro-blogging follow-up for the local image campaign. For example, during the Western Fair, Chengdu People's Government Information Office official micro-blog "Chengdu Release" posted series of news related to this event with the form of "focusing on the Western Fair" column, and there were some positive comments on Chengdu from the guests, such as "Chongqing Mayor Huang Qifan visited and observed Chengdu tourism and leisure, cultural and creative industry development and he stated that the Easter park keeps authentic industrial elements, and also fully integrates into the most modern music elements, it's so creative". And former Japanese Prime Minister Hatoyama Yukio commented that Chengdu is a beautiful and modernized city. For "Chengdu Release" which has over 1,600,000 followers, this information undoubtedly did a positive spread of local image, and played a role in agenda setting to its followers.

The institutions' blogs with a large number of followers have a very good agenda setting effect. They play an important role in the daily dissemination of information and the local image building. And the institutions (especially the media) also can reflect local image through micro-blogging the news events. For example, on October 21st 2011, "Xiao Yueyue Event", a 2 year old girl was successively crushed by two cars at Foshan. In 7 minutes, there were 18 strangers passing all turn a blind eye, nonchalance but go. At last, a scavenging woman approached to lend a helping hand. This event led a widely debate by micro-blog users. About Foshan local image, several representative comments from micro-blogging users were collected by the writer: "A fresh life had been ruined by rich Guangdong, Foshan people", "The apathy of Cantonese, it's time to rethink the market economy society! Foshan's apathy, Guangdong's apathy, the indifference of the people! We can't tolerate it and it's time for us to rethink the market economy society". "Foshan really deserves to be China's most apathy city!" "Foshan, a place you can choose not to live, live in the death is a continuation of Life. It should just call "Shan" (mountain) instead of "Foshan" (Buddhist Mountain)." Obviously in this event Foshan people's apathy reflects the business atmosphere of this city, which is sorely lacking the most basic moral conscience and human kindness.

（2）Agenda Orientation of Personal Micro-blogging Information Resources

Although most micro-blogging audiences are influenced by institutions' micro-blogging information, the interpersonal communication advantage reflected in the personal micro-blogging information resources can't be ignored. The followers, as the receiver, repeatedly refresh the information of the people they care about to get the update information from communication subject. By this way, audiences will inevitably be influenced by individual micro-blogging agenda-setting. The information released by micro-blogging users in their own interest or attention may not get into

audience view from micro-blogging square and also did not get strong communication effect because of lacking fans. But after the interpersonal communication and group transmission, it is also possible to obtain a higher degree of the attention between acquaintances and have a certain impact.

Of course, there is also some celebrities will conduct the agenda setting for fans through consciously talking about the topic. Such as they will release some topics or questions they thought valuable to interact with fans or increase the influence of the issues though the form of releasing series of the micro-blogging, or through the fans forwards, comments, or hyperlinks expansion to the relevant topic, attract the audiences' attention. For example, some reporters often release some news which could not be seen in traditional media for various reasons, or express their views and opinions to attract the attention and response of internet users. In this way the content they spread can often receive attention quickly, and quickly become a hot discussion.

In addition, the communication subject of the micro-blogging information resources can "weaken or strengthen the topics taking about" though some technical methods. Such as delete, add special symbol (for example in sina weibo, the symbol "#" is used to mark the scope of topics), transmit repeatedly, and forward audience comments to achieve agenda setting.

（3）The Interaction between the User "Strengthening" the Information Resource Agenda Settings

The spillover effects, formed by the city's political, economic and cultural aggregation function, and the reality demand or imagine consumption from the individual and organizational, make the city, individual and organization connected to each other becoming a reality or potential, direct or indirect benefited party and risk taker. This community relationship of interests is a mutual stakeholders' relationship. They embody the partner relationship with the public interests as its axis which is formed by local image communication in the social favorable development and related groups and organizations. Therefore, after the information resources forwarded by the institutions or personal micro-blog, or whether consciously or unconsciously set the agenda for visitors, it usually leads some audiences to have a further discussion around the issue by the way of giving some comments or forwarding. The spillover effects, formed by the city's political, economic and cultural aggregation function, and the reality demand or imagine consumption from the individual and organizational, make the city, individual and organization connected to each other becoming a reality or potential, direct or indirect benefited party and risk taker. This community relationship of interests is a mutual stakeholders' relationship. They embody the partner relationship with the public interests as its axis which is formed by local image communication in the social favorable development and related groups and organizations. Therefore, after the information resources forwarded by the institutions or personal micro-blog, or whether consciously or unconsciously set the agenda for visitors, it usually leads some audiences to have a further discussion around the issue by the way of giving some comments or forwarding.

Some scholars believe that We Media can make the "noise" reduced to a minimum level in the communication process. Because micro-blogging information recourses have a strong interaction, the audiences can directly access the information which is released by communication subject at first time. Even though the audiences may have different understanding, they can eliminate the "noise" in time through the interaction with the author. Therefore, during micro-blogging transmission, the information released by opinion leader may minimize misunderstandings. On the other hand, audience can through forwarding of the information to contact the information source directly, which guaranteed the authentic and comprehensive of information in a great degree. Audiences can directly express their own opinions or provide some supplementary information of the issues. These timely, sufficient and free expressions make the opinions of communication subject and audience shown in public. Different opinions mutually penetrate, fuse and extend, which will affect other visitors' focus, understanding and judgment of the issue. This process not only "strengthens" the agenda-setting

function of institution and personal micro-blogging, but also provides the space to form the new agenda, and plays a more effective role in the local image spreading as well.

Keywords: Mine Internet of Things; Multifunction Gateway; Optical fiber Ethernet; WiFi; ZigBee

Abstract. Mine Internet of Things can be divided into 3 layers: sensing layer, network layer, application layer. Multi-functional gateway of Mine Internet of Things works at the edge of the network layer, and it both has access and transmission functions. It can make use of various communication media like optical fiber, cable and radio waves. It also adapts to a variety of protocol interfaces like industrial ethernet, WiFi, ZigBee, CAN, RS485, RS232 and so on. It can convert information of sensing layer into ethernet data which can be transmitted by Gigabit fiber ring network.

Introduction

Internet of Things is the network of "thing to thing", whose access of information and transmission need a ubiquitous network. The ubiquitous network needs to be interconnected and fused by all kinds of existing or newly-built medium, protocols and heterogeneous networks[1]. Because of the high speed, high reliability and intrinsic safety, optical fiber communications has been the first choice of transmission media for mining backbone transmission network.

There are as many as dozens of monitoring and controlling systems in mine. Networking equipments of the systems are not almost the same, particularly networking protocol. Therefore, during building Internet of Things in mine, we urgently need the sub-station and multifunctional network node equipment that can be compatible with a variety of monitoring and controlling systems. The basic features of the equipment include: 1) easy accessing voice, video, and various monitoring and controlling data; 2) achieving transmission media flexible adapter from wired and wireless to optical fiber; 3) offering a variety of standard transmission interfaces, such as RS485, RS232, CAN, Ethernet,WiFi, ZigBee, etc.

According to this demand, this paper design multifunctional, multi-media, multi-interface gateway in mine Internet of Things based on optical fiber GbE (Gigabit Ethernet), in order to achieve a variety of Monitoring and controlling data access high-speed fiber-optic transmission network, which is real-time, long-distance, without distortion transmission.

Corresponding to three layers of functional structure of IOT[2]: sensing layer, network layer and application layer, the gateway in Mine Internet of Things mainly works at the edge of network layer, and it both has sensory information access and transmission network functions. Because the gateway in Mine Internet of Things has diversity function and flexibility interface matched and used which can cover the basic requirements for the various requirements of transmission in mine.

Overall Architecture of Gateway in Mine Internet of Things

The gateway in Mine Internet of Things utilizes embedded systems, FPGA and ASIC technologies integrated overall program which is modular, building-block design structure. The main function modules of it include embedded control management module, FPGA interface conversion module, Gigabit Ethernet switching module, WiFi high-speed wireless communication module, ZigBee/IEEE802.15.4 wireless sensor access module and power module. The specific architecture is shown in figure 1.

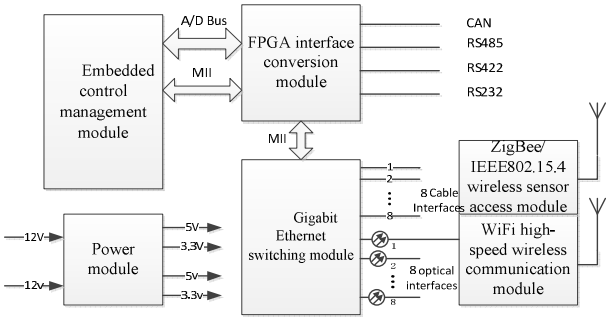

Fig.1 Overall architecture of gateway in mine Internet of Things

Wired communication is the primary means of transmission in mine. The optical fiber industrial Ethernet has been widely used as backbone transmission ring network in mine. Therefore, the sub-station takes Gigabit Ethernet switch module as core. The configure interface converter module achieves data conversion between Ethernet and other industrial field bus (wired) interface, and embedded control management module is responsible for the entire sub-station configuration management, protocol conversion, and remote control management. The above three modules and power modules constitute the motherboard of gateway Internet of Things.

WiFi and ZigBee module are designed as wireless boards. They can work independently, and to be used to access voice, video, other high-speed mobile data, and wireless sensor nodes, personnel position data, etc.

Ethernet switch module selects VSC7429 which is carrier-class Ethernet switch chip of Vitesse. VSC7429 is a complete system on a chip, and integrated processor MIPSTM in a single chip, that provides 8 electrics, 8 fibers and 16 Gigabit Ethernet interfaces. It has capabilities of networked timing and performance monitoring, and supports storm suppression, port mirroring, LACP link aggregation protocols and RSTP spanning Tree Protocol, and has 4096 VLAN, rich QoS and ring protection feature. It aims at multi-fiber Ethernet ring network interconnection and access application, fully functional, and low-power of Ethernet switches.

The power board is made up of two DC/DC modules which are respectively 12V to 5V and 12V to 3.3V. This paper focuses on embedded control and management module, FPGA interface converter module and hardware configuration and design of wireless boards of motherboard.

Hardware Design

Design of Embedded Controlling and Management Module.

See diagrams 2 for the formation principle of embedded control and management module. As shown, with MPC8308 of PowerPC as its core, matching 16M Nor Flash and 1Gbit DDR2, so it can run the embedded operating systems and the minimum embedded system in the software of the communication, management and controlling working in various of networks. Take advantage of the MII interface of network controller eTsec0 within the MPC8308, which can extend the common Ethernet transceiver IP101A to form the adaptive Ethernet interface with the rate of 10/100Mbps and regard as the interface of remote managements, network debugging and data communications. The A/D Bus (address/databus) and the MII interface of eTsec1 should be connected to the FPGA at the same time, so it can not only ensure that the data and the management, controlling channels of the MPC8306 to Ethernet switch going ahead, but also ensure that the RS232/RS485/CAN Ethernet monitoring data which is packaged by the FPGA hardware to access to Ethernet rapidly.

The Console interface is used exclusively for proximal configuration and management of the switch. The other ways to configure and manage the switch, such as Web, Telnet and so on, must be used after the basic configuration relying on the Console. Because they often need the help of the IP address, domain name, equipment name to realize, but the newly purchased switch containing these parameters is apparently impossible.

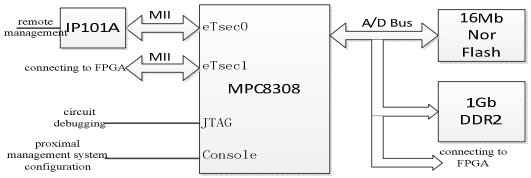

Fig.2 The hardware of embedded control and manage module

Design of Interface Conversion Module on FPGA.

The interface conversion function of gateway is mainly realized by FPGA, which has two advantages: firstly, the standard interfaces in the design are RS232/485/422 and CAN, but the sites of mine might use other protocols and standards, the FPGA is field programmable, so it can provide various conversion interfaces what we needed; secondly, if we convert and package by software after CPU, could not ensure the real time data when the rate of the monitoring data more than 100kbps.

With reference to Fig.1 we can see that the FPGA module has a lot of interfaces and wide kinds. The kinds include the address/databus and MII bus connected to the MPC8306, the UART, SPI connected to various monitoring equipment and field bus, which should be realized through hardware description language within FPGA. There also has an important task in FPGA, which is to assemble Ethernet packet after the multiplex serial data multiplexed and send to Ethernet switch directly through MII interface, in order to achieve high-speed data transferring with hard real-time guarantees. All the related design work has immature VHDL language module in the authors' laboratory, readers are referred to Reference［3-5］ and will not be described here.

Design of Wireless Board.

The wireless board with Wireless Routing switch chip RT7620A of Ralink as the core, which supports three modes of 802.11b/g/n and the maximum transmission rate up to 300Mbps, having five Ethernet switch internally installed, supporting HNAT function, and having strong routing transmit capability. It also supports two UART (the serial port). One is regarded as console debugging interface, the other is connected to CC2530 to form wireless communicating interface of ZigBee/IEEE802.15.4[6].

The WAN port and one of the LAN ports in the built-in switch are connected with Ethernet transceiver AR8033 and optical fiber transceiver module, forming two fiber communication interfaces, so that the board has a Gigabit WAN interface when the board is connected with the main board. When used independently, concatenation of multiple boards through fiber can form a linear network even ring.

In Figure 3, the electrical interface consists of Ethernet line transformer and related resistance-matching circuit, signal indication LED for communicating and RJ45 joint. The optical interface mainly consists of fiber communication transceivers and related resistance-matching circuit, power filtering circuit.

The main performance indexes of wireless board:

1) Supporting 802.11b/g/n and the wireless maximum transmission rate up to 300Mbps;

2) Supporting three adaptive electrical interfaces with the rate of 10/100Mbps, one optical interface with the rate of 100Mbps, one optical interface with the rate of 1000Mbps;

3) Supporting the WDS function, this can realize the concatenation of wireless;

4) Supporting the AP Client mode, this can be connected to wireless AP;

5) Supporting no longer more than eight SSID;

6) Supporting the mutual switching and transmission between Wife, Ethernet and ZigBee.

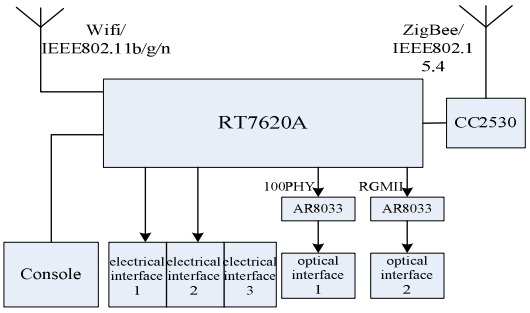

Fig.3 The principle of wireless router board

Summary

Using a variety of advanced technologies and sophisticated results, we design a gateway in mine internet of things, which can adapt to a variety of the transmission mediums and protocols. The gateway includes two independently running boards: the main board and the wireless communication sub-board. The main board takes the Gigabit Industrial Ethernet as the core, which has a variety of interfaces used in optical fiber communication and cable communication which is needed in coal mine underground. It can complete the real-time transfer between gigabit Ethernet based on optical fiber, cable and field bus. The wireless sub-board achieves the interchangeable data transmission between WiFi, ZigBee and Ethernet. Therefore, the gateway in mine internet of things can almost meet the demands for every aspect of networking communication in coal mine underground.

Keywords: Measurement; Business systems; JSP; IntelliJ IDEA; The oracle database

Abstract. On basis of the need of measurement, this paper is dedicated to build the IntelliJ IDEA + Oracle based metering management information system mainly in computing process. According to the needs of the business, we designed the multiple functional modules, gave the system architecture, develop platform and the database design strategy and completed the overall design of the system. Meanwhile we also made the profound discussion on some key technologies in the metrology management system. The research and design of the system thoroughly transforming the existing operation and service mode, fundamentally realize enhancing the scientific and technological content of department of metrology by means of computer science and promote the management standardization and efficiency of measurement work

Introduction

Along with the development of economic globalization, rapid expansion of enterprises, great improvement in operating efficiency, measurement testing department transformation from the original FaZhiXing technology supervision and management institutions to service-oriented institutions, measurement testing department is getting unprecedented development in the process of meet the testing needs of enterprise. Accordingly, the rapid development of computer technology also makes the measurement business management gradually transform from manual management mode to the computer automation. The design of the measurement of business management information system with the development of the informatization construction of legal metrology institutions across the country, as well as a variety of software and hardware facilities, measurement management system has become more and more urgent to research and design requirements. Construction of measurement management system is in order to improve the efficiency and the purpose of promotion. However only through the planning and development of information resources it can play its role to the greatest extent. In this paper, design and research of metrology management system requirements for measurement, as well as the measuring mechanism of daily office, personnel management, file system to be able to realize integration, standardization, unification, so as to realize the real office automation.

The Related Background of Metering Management System Research

The Related Technology Applied by System

This system uses the development pattern which is the JSP reception combined with the background of ORACLE database B/S structure taking JAVA as a development language so that the program code and structure are optimized, and also can improve the efficiency of program. This system is developed in IntellijIDEA7.0.1.In this paper, the development environment is IntelliJ IDEA7.1 with Oracle11g. IntelliJ IDEA, one of the most useful Java development environments, is a relatively new Java IDE. Highly optimized IntelliJ Idea makes it much easier to common tasks, the Idea support many integration function, it is more important that they designed very easy to use. Idea support XML code

in the implementation, the Idea and correction of XML, the Idea of support structure of the JSP.ACTS on the many functions of ordinary Java code applies to the JSP (such as the integration of functions), at the same time support the JSP debugging; Support the EJB, although it does not include the special support to individual application server. Idea to support the Ant build tool is not only the target it support to compile and run the program before and after the operation target, but also support the binding keyboard shortcuts. When editing an Ant build an XML file, the Idea of the Ant project also part of the XML to provide support. IntelliJ IDEA is known as a development platform is the best JAVA IDE. Oracle oracle11g is the latest company to launch a database, support for UNIX platform has the very good database management functions such as processing speed, high level of security, support flash and perfect recovery, do a few database load database, can be done within 30 s failover, grid control, and data warehouse is also very strong so this design USES the oracle. At the same time the system development environment also provides a large number of alternative data control, we can easily establish the connection between the database and on the basis of this connection, use a variety of common data components for database operations.

The Feature of the System

Traditional manual processing data is very complicated, and the efficiency is very low, while with the present rapid development of network technology, and through modern network management system, It can be dealt with related business anytime and anywhere by passing the shared information measurement. The present application of network technology in measuring work for effective management, control, can improve work efficiency, and it is a good way to standardize business processes, conducive to more effective management of metrological work. In order to adapt to the new situation of the need of measurement management and service work, we make the measurement work further to a higher level and development of the new field, introduced in the informatization construction of metrological work is particularly necessary.

This system is to establish a complete and orderly metering management system, and fundamentally change the existing operation mode and service mode, basic implementation using computer technology on the analysis of original data processing, the measurement of management and service implementation of computerized management, to serve by units or individuals provide standard calibration certificates and test reports and calibration certificates and relevant conclusions and data, upgrading of the technological content of metrology department service, promoting the administration of metrological work standardization and high efficiency.

The System Planning and Analysis

Developing measurement management system needs to analysis the demand and design overall, use the analysis system objects, design the system architecture and database structure, decide to use the development tools and background database, and plan and project development progress. This work is very important in the actual project development process.

The Design of System Structure

In this system, the core technology need to be solved is how to access data, by appropriate means. And for different needs, we should choose what kind of data the collocation of components to achieve a specific purpose. The data access is as shown in figure 1. The picture data in this system is to access the operation process of abstraction. The above takes data principle as the foundation combines with the characteristics of the measurement management system, the whole system will be divided.

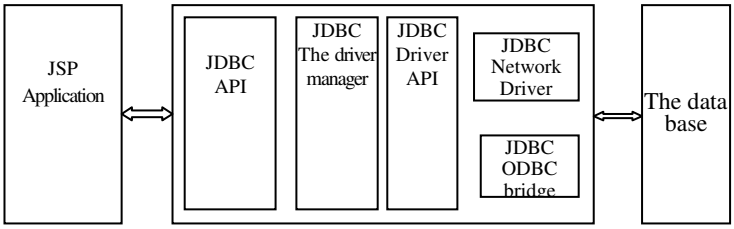

Figure 1. Data deposit and take out picture

The Analysis of System Function

The main purpose of measurement system is to improve the working efficiency of the staff, make itself equip a shared information platform for personal office. A preliminary set of main function modules includes: login module, my work, data maintenance, customer service, interactive platform. When the user login successfully into the measurement business system after first saw four big modules, And then in each module is divided into several small modules. They completed the corresponding increase respectively, query, modify, delete messages, and other functions. Users can easily query, modify the corresponding information. As is shown in figure 2:

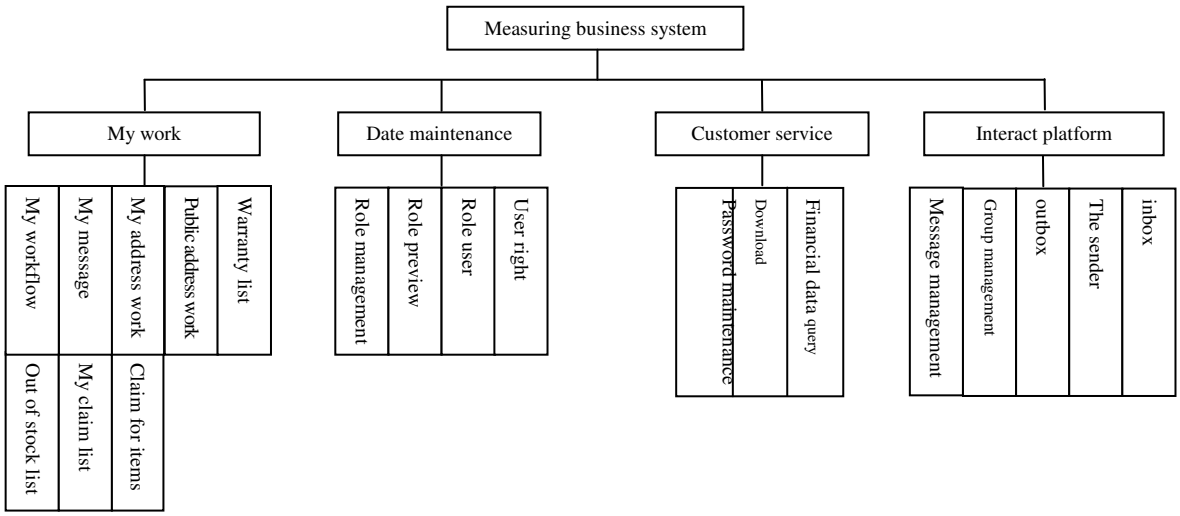

Figure 2. The system function module chart

System is the first impression to the user interface, the user has a close relationship with whether to choose to use this system, so the design and implementation of related becomes very important. The system has designed the a series of modules, namely, the user login module, address list module, sending information module, the register of products shortage module, the input of repair form information module as well as various kinds of solution to deal with the condition when abnormalities occurs.

In multiple modules, take the current shortage of supplies register module as an example, we defines a public DBUtil class, it respectively achieve the current database connection, release a database connection, released a statement, and closed results function. If you want to connect to the database, only to call get Current Connection DBUtil class () method.

Then is the Dao class to realize database operations, Dao class it first call to get Current Connection DBUtil class () method, which connect to the database then define the database query, modify, delete, and insert a series of operations. As long as the corresponding methods of the Dao can be used in Action, the database can make operation. For example the user who selects good claims department, choose the type of products, fill out the required information (add an asterisk behind for mandatory

fields) and then click the submit the data of the page will be submitted to the database. The interface as is shown in figure 3:

The Test Of The System

Under carefully controlled system environment, by using the corresponding technical means, a set of good structure in advance to execute a program test cases we can find the problems existing in the system, and finally confirm the system function. The performance is in line with the requirements. Again and determine the test objectives and methods, as well as the test cases used in this system and the test report. After several rounds of testing, by correcting the error code, ensuring the measurement management system we can achieve high quality, high efficiency operation.

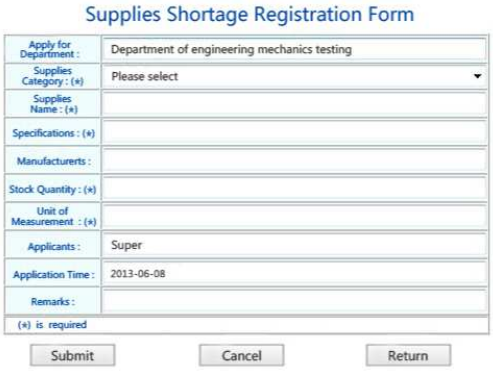

Figure 3. Shortage of products interface

Unit test Cases

Unit testing is testing each module individually, it is an important work before the unit test that make sure the authentication module interface and design specifications are consistent, all the major processing path of module testing and comparing with the expected results, but also for all the wrong path test. To review the source code, reference design specifications, statements to check whether the source program is conform to the requirements of the function of logic. As is shown in figure 4:

The test case number	Name of test cases	conditions	The output
1	Input the correct common user name and password, login successfully	1) user name = '800' 2) the password = '123123'	The test pass
2	Enter incorrect normal user name and password, login failed	3) user name = "mm..." 4) password = "11"	The test pass
3	Click on the public address book information query. Choose the department name to query, display the related information	5) department name = "department of medical equipment testing"	The test pass
4	Click the repair button to add the relevant information in my report, according to the modified successfully	6) to fill in and select the relevant information	The test pass
5	Delete the inbox information, select the relevant information to delete, delete successfully.	7) such as "delete titled": 'QQQ' information	The test pass
6	Change the password input relevant information, according to modify success.	9) the username = 800 10)Old password = 123123, 11) the new password = 123 12)Confirm new password = 123,	

Figure 4. The test use case diagram

The Test Report

After two rounds of testing, This system has implemented a total of 15 cases, found a problem, and solved a problem, There is no legacy, no denial. After fully test, the quality of the system is reliable, and can be released. As is shown in figure 5:

Rounds	Find the problem	Resolve problem	The solution	Deny problem	Leftover problem
1	1	1	Check the code, find the error code	0	0
2	0	0		0	0

Figure 5. Test report

Conclusion

In this article, we made a elaborate conception for IntelliJ IDEA + Oracle based on the general structure. Measurement management system, throughout the whole business process as the main line, according to the demand of the measurement test, design the function of each module, and construct a complete measurement management system, make use of several key technologies in the design and research has been fully reflected. In this paper, the design and research of the system is convenient to efforts to develop the masses of users to use a function of the perfect measurement management system, the system operating efficiency of above 90% has the very good practical value.

Keywords: wireless networks; conflict prevention;channel

Abstract. In the campus WLAN wireless networks, transfer speed of network data is attracted great attention of users. How to solve conflict problem occurred in the network data transmission process has become the main goal of the campus WLAN network optimization. This paper presents campus WLAN wireless networks conflict resolution based channel mapping anti-collision algorithm. According to the amount of data to be transmitted in the network, the data length is estimated to provide conflict resolution with support data. On the basis of the channel mapping anti-collision algorithm related theory, conflict resolution model is established. Experimental results show that the proposed algorithm used in resolving conflict in campus WLAN wireless network can reduce the probability of data conflict happened in channel, so as to improve the performance of campus WLAN wireless network.

Introduction

With the campus WLAN wireless networks widely used in universities, the data transmission problems in the network has become the core issue need to be resolved during the operation of the network[1]. Assuming task load need to be transmitted is large, task conflict tends to happen [2]. Therefore, the campus WLAN Wi-Fi conflict resolution has become a hot issue need to be studied in computer field, and attracts the attention of many scholars[3]. At this stage, the main resolution of campus WLAN wireless network conflict includes conflict resolution method based on non-uniform distribution algorithm, conflict resolution method based on ant colony algorithm and conflict resolution method based on decision tree algorithm[4]. Among them, the most commonly used method of conflict resolution is based on decision tree algorithm[5]. As the campus WLAN wireless networks conflict resolution method has a very broad space for development, itbecomes an important research topic in the field of computers and has a brilliant future[6] .

Relevant principle of conflict resolution in campus wireless network

A. Estimation of data length in campus WLAN wireless network

During the process of campus WLAN wireless network conflict resolution, the length of data needs to be predicted, thus providing the basis for the campus WLAN Wi-Fi conflict resolution. Details of which are described below:

Time interval of campus WLAN wireless network data transmission is set $e=[e(0),e(1),\cdots,e(P-1)]^T$ per frame, the number of all data can be describedby q . Time interval of campus WLAN wireless network data transmission needs to obey the distribution $d \sim p(e,q)$, based on the distribution data, the prediction of data length can be achieved.

The following formula can be used to calculate data transmission time interval in campus WLAN wireless network:

$$\hat{p} = arc\min_{\overline{n}\in\chi} \sum_{p=1}^{+\infty} K(\overline{p},p)p(p|d) \tag{1}$$

In the above formula, $L(\overline{q},q)$ can be utilized to describe the distribution of time interval of the campus WLAN wireless network data transmission, δ is the set constituted of all data, the contents as follows:

$$\varepsilon = \{\overline{r} \,|\, f_1 + 2f_r \le \overline{r} \le R\} \tag{2}$$

Wherein, Q can be used to describe the maximum value of all data size which needsto be transmitted in campus WLAN wireless network.The following equation can be employed to describe Bayesian cost function in the data length forecasting process:

$$L(\overline{q}, q) = (\overline{q}, q)^2 \tag{3}$$

According to the following formula to calculate the maximum value of posterior probability prediction :

$$L(\overline{q}, q) = \begin{cases} 1 & |\overline{q}, q| > \dfrac{\Delta}{2} \\ 0 & |\overline{q}, q| \le \dfrac{\Delta}{2} \end{cases} \tag{4}$$

In the above formula, Δ can be used to describe the transmission state parameters of campus WLAN wireless network data. According to the description above, the following formula can be applied to predict data transmission length in campus WLAN wireless network:

$$\overline{q} = arc \max_{\overline{q}} p(\overline{q} \,|\, e) \tag{5}$$

According to the above- described method , capable of predicting length of campus WLAN wireless network data, thus provide the basis for the campus WLAN Wi-Fi conflict resolution.

B. The establishment of conflict resolution model

The task load transmitted in campus WLAN Wi-Fi channels per unit of time is set to be z, the channel transfer efficiency blurred value is u, $u \in [0,1]$, the following formula can be utilized to calculate service efficiency incremental coefficient of channel:

$$u \in [0,1] \tag{6}$$

According to the method outlined above, mapping relationship between task scheduling and the channel transmission is established. In this mapping relationship, the data set constituted of entire campus WLAN wireless networks transmission tasks is $u = \{u_1, u_2, \cdots, u_q\}$, where constitute that which is the task of the first channel needs to be passed. Setting, where u_k is task need to be transmitted in k-th channel.Setting, w_k is transmission requirement for channel T exerted by task waiting for transmission, and the requirement of $U_k, w_k \in [0,1]$ needs to be hit. y_k is priority of massive tasks in the campus WLAN wireless network data transmission process. The higher priority task will be transmitted in prior, $y_k \in [0,1]$. During the data transmission process, task quantity can be transmitted in channel is limited,it is necessary to meet the following requirement:

$$y_k \in [0,1] \tag{7}$$

Efficiency of scheduling tasks can be calculated using the following equation:

$$f = |u - w| = \sqrt{(u_1 - y_1 w_1)^2 + (u_2 - y_2 w_2)^2 + \cdots + (u_q - y_q w_q)^2}$$
$$= \sqrt{\sum_{k=1}^{q} (u_k - y_k w_k)^2} \tag{8}$$

Wherein, f is the efficiency of task scheduling, and the greater the dispersion u and w are, the higher efficiency of task schedulingis.

The following formula is employed to establish a conflict resolution model in campus WLAN wireless network:

$$\min f = \sqrt{\sum_{k=1}^{q} (u_k - y_k w_k)^2}$$
$$s.t. h(u_1, u_2, \cdots, u_q) = 0$$

$$u_k, w_k, y_k \in [0,1]$$
$$k = 1, 2, \cdots, q \quad (9)$$

According to the method described above, it is possible to estimate the length of transmitted data during the campus WLAN wireless network data transmission process. . Based on the results of estimation, the conflict resolution model is founded to prevent conflict happened in campus WLAN wireless network.

Simulations and Results Analysis

In order to verify the effectiveness of the proposed method, an experiment was conducted. During the experiment,it is necessary to establish a campus WLAN wireless network simulation environment, the distribution channel in the campus WLAN wireless network can be described by the following figure:

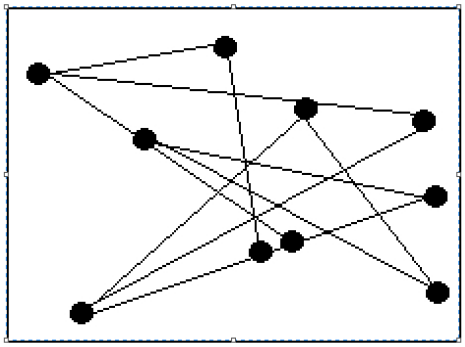

Figure 1 Channel Distribution

In the process of campus WLAN Wi-Fi conflict resolution experiments solved with different methods, the probability of channel conflict tasks happens can be described by the following figure:

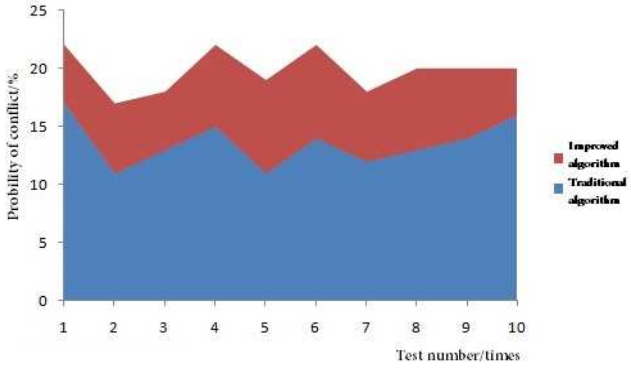

Figure 2 Comparison of channel conflict probability with different algorithms

According to the figure above, it can be learned that by using proposed algorithm to conduct the campus WLAN Wi-Fi conflict resolution experiment, assuming the campus WLAN wireless network task size is too large, caused an augment in the probability of channel conflict.

The above experimental data were analyzed, and Table 1 can be obtained as follows:

Table 1 Channel conflict probability table

The amount of data (ten thousand)	Conflict probability of traditional algorithm (%)	Conflict probability of proposed algorithm（%）
1	17	5
2	11	6
3	13	5
4	15	7
5	11	8
6	14	8
7	12	6
8	13	7
9	14	6
10	16	4

According to the above experiment, it can be learnt that the use of this algorithm for solving conflict in campus WLAN wireless network, can greatly reduce the probability of channel conflict, showing a strong advantage.

Conclusions

In the paper, the campus WLAN wireless networks conflict resolution based channel mapping anti-collision algorithm is raised. According to the amount of data to be transmitted in the network, the data length is estimated to provide conflict resolution with support data. On the basis of the channel mapping anti-collision algorithm related theory, conflict resolution model is established. Experimental results show that the proposed algorithm used in resolving conflict in campus WLAN wireless network can reduce the probability of data conflict happened in channel, so as to obtain the satisfactory results .

Large-scale data mining and distributed processing in big data Internet

XING chun-zhi[1,a]

[1]Henan Radio & Television University, Zhengzhou Henan 450008, China
[a]hndd2013ks@163.com

Keywords:big data internet; data mining; distributed

Abstract. With the development of Internet， various Internet-based large-scale data are facing increasing competition. With the hope of satisfying the need of data query, it is necessary to use data mining and distributed processing. As a consequence, this paper proposes a large-scale data mining and distributed processing method based on decision tree algorithm.

Introduction

With the continuous development of computer data processing technology, the application of this technology in data mining has become increasingly widespread [1]. Thus, large-scale data mining and method of distributed processing has become the core problem of data management, raising widely attention among many scholars [2]. At this stage, the major methods for large-scale data mining and distributed processing include the data mining and distributed processing method based on BP neural network algorithm, means clustering algorithm and variety constraint model [3-4].Among them, the most commonly used method is based on variety constraint model. Due to the distributed data mining and processing methods have broad space for development in data management, therefore, has been a great concern, has a huge potential for development[5].

Large-scale data mining and distributed processing methods revenant principles

A. fuzzy clustering on large-scale data processing

Let $Z=\{z_1,z_2,\cdots,z_q\}$ is the set of the large-scale data in big data Internet, using the following formula to describe the target function of large-scale data analysis,

$$L_p(Y,B)=\sum_{k=1}^{q}\sum_{l=1}^{e}y_l^p f_{kl}^2(z_k,b_l) \tag{1}$$

Let the state parameters of large-scale data are $e,q,p,d=1$, the set of the clustering center of all large-scale data is $B_{(d)}=(b_1,b_2,\cdots,b_e)$. Based on the following formula, the update and transition of the large-scale data in big data Internet can be manipulated.

$$y_{kl}=\frac{1}{\sum_{m=1}^{e}\left[\frac{f_{kl}}{f_{km}}\right]^{\frac{2}{p-1}}} \text{ when } f_{kl}\neq 1$$

$$y_{kl}=0 \text{ when } e_{kl}=0, l\neq m$$

$$y_{kl}=1 \text{ when } e_{kl}=0 \tag{2}$$

According to the following formula to calculate the average property features large-scale data:

$$b_l=\frac{\sum_{k=1}^{q}y_{kl}}{\sum_{k=1}^{q}y_{lm}} \tag{3}$$

Compare the above conclusion with the next the average property features, assuming following conditions are met, then complete the clustering large-scale data processing in a bigdata Internet, otherwise repeat the above steps until it reaches the maximum number of iterative processing.

$$\left|b_d - b_{(d+1)}\right| \le \varphi \tag{4}$$

B. Achievement of large-scale data mining

Let the set of known large-scale data can be described as $Y = \{(y_j, z_j) \mid j = 1, 2, \cdots, total\}$, among them, $y_j = (y_{j1}, y_{j2}, \cdots, y_{je})$ can be used to describe the element in the set, $(B_1, B_2, \cdots, B_e)$ can be used to describe the corresponding properties. Using the following formula can calculate the expected information of the large-scale data

$$J(p_1, p_2, \cdots, p_n) = -\sum_{k=1}^{n} \frac{p_k}{total} \log_2 (\frac{p_k}{total}) \tag{5}$$

Using the following formula an optimal decision tree can be built based on the above data:

$$B_j = MIN + \frac{MAX - MIN}{P} \times j \tag{6}$$

, where $j = 1, 2, \cdots, P$.

For each data which reaches the maximum information gain ratio, regard it as the branch of the decision tree and build a node of decision tree. Build the corresponding branch based on the different weight of data properties, by querying the leaf node to finally complete the building of decision tree.

According to the method described above can build an optimal decision tree. Based on the decision tree, classify the data so that query the needed types of data and finish the data mining finally.

Experiment of Simulation and the Analysis of the Result

In order to verify the correctness of large-scale data mining algorithm proposed by this paper, it is necessary to perform an experiment. During the experiment, the big data Internetis usedas the object and the large-scale data in the Internet are used as the sample data.In the case that the sample amount in the Internet is under 50 thousand, respectively using traditional algorithm and proposed algorithm for large-scale data mining, the results obtained can be described by the following figure.

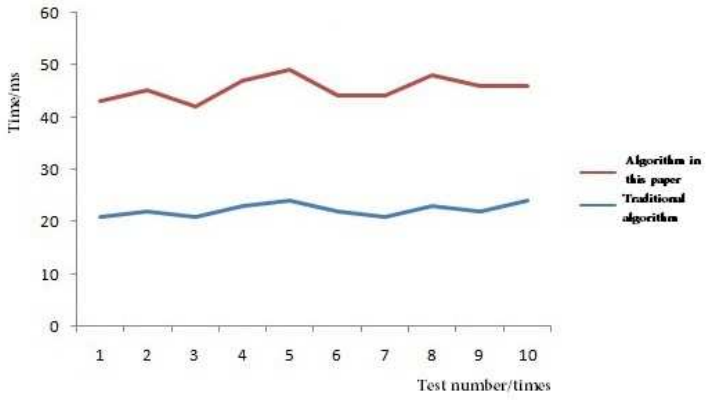

Figure 1, Time consumption when the amount of data is 50 thousand

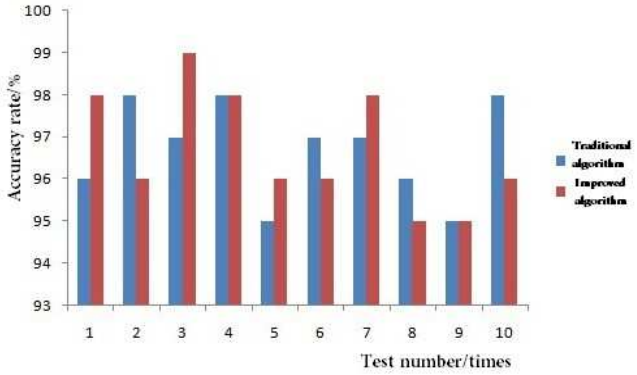

Figure 2, The accuracy of different algorithms when data amount is 50 thousand

Organize and analyze the above data, the following table 1 can be obtained:

Table 1, Experiment data table when the data amount is 50 thousand

No.	Time（ms）		Accuracy（%）	
	Traditional	Proposed	Traditional	Proposed
1	21	22	96	98

9	22	24	95	95
10	24	22	98	96

Based on the table above, when the amount of data is under 50 thousand, using the proposed algorithm by this paper, the time used by data mining and the accuracy are approximately the same as the traditional algorithm.

When the amount of sample in big data Internet is 100 thousand, respectively use the traditional algorithm and the proposed algorithm to perform large-scale data mining, the obtained data is shown as following graph:

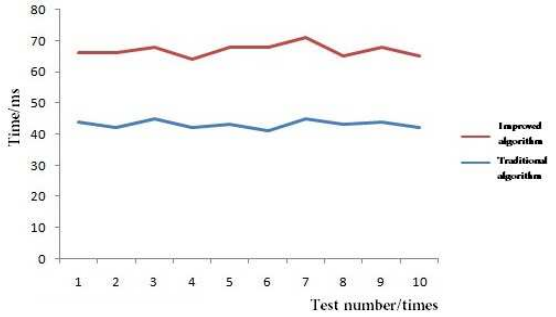

Figure 3. Time consumption of different algorithm when the amount data is 100 thousand

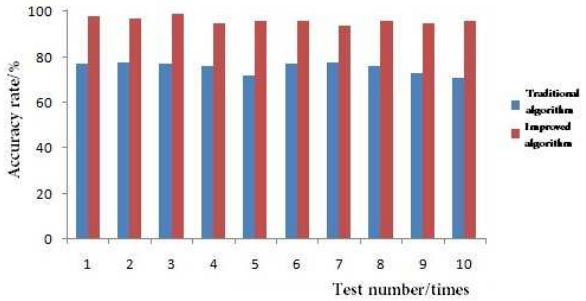

Figure 4.Accuracy of different algorithm when the amount data is 100 thousand

Organize and analyze the above data, the following table 2 can be obtained:

Table 2. Experiment data table when the data amount is 100 thousand

No.	Time（ms）		Accuracy（%）	
	Traditional	Proposed	Traditional	Proposed
1	44	22	77	98
2	42	24	78	97
3	45	23	77	99
4	42	22	76	95
5	43	25	72	96
6	41	27	77	96
7	45	26	78	94
8	43	22	76	96
9	44	24	73	95
10	42	23	71	96

According to the above data, when data amount is 100 thousand, using the proposed algorithm to perform large-scale data mining, the consumption of time is slightly shorter than the traditional algorithm.

Conclusions

This paper presents a large-scale data mining and distributed processing method based on the decision tree algorithm. For large-scale data, using fuzzy clustering process to obtain a big data Internet that highly related to the search target. According to the decision tree mining algorithms and its related theory, a large-scale data mining decision tree can be built and achieve big data Internet data mining. Experimental results show that using the improved algorithm, the time consumption of data mining can be shorten and accuracy of data mining can be improved.

[a]4066614@qq.com

Keywords: Internet of Things (IOT), smart home, monitoring platform, ZigBee.

Abstract. In order to popularize the intelligent monitoring in households, this thesis is aimed to conduct researches on“Household Monitoring System based on the Internet of Things (IOT)”and starts with the design of this system. General technology concerning household video monitoring and home appliance controlling in computers, mobile phones, etc. is explored in this thesis and a household monitoring system based on IOT is set up. According to experiments, the household monitoring system has various functions such as operating once plugged, ad hoc network, various and interactive controlling methods and friendly serial ports.

Introduction

Along with the rapid development of computer technology, sensor technology, communication technology and Internet technology, smart home has become the trend of our future life, which connects all the household items through the network and conducts remote monitoring and intelligent management of the household so as to create a safe, comfortable and convenient environment. The smart household with the application of Internet of Things is a highlight of China's current economic and social development. With the theme as “Research and Development on the Household Monitoring System Based on the Internet of Things”, this thesis starts with general technology concerning household video monitoring and home appliance controlling in computers, mobile phones, etc. to explore a household monitoring system based on Internet of Things. This paper is contributive to the development and practical application of measurement and control, promotion of the Internet of Things technology, development of the Internet of Things discipline and improvement of smart households.

Design of the Framework of Household Monitoring System based on Internet of Things

Based on system requirements and the Internet of Things technology, the framework of household monitoring system is designed in Figure 1. The whole system architecture is divided into three layers: perception layer, network layer, application layer. The perception layer connects all the household items through sensors, actuators, etc on wireless network. The network layer is the information transfer media between the other two layers. And the application layer is sort of monitoring operation for users to connect with the system and to operate household items.

ZigBee equipment in this system is JENNIC JN5139 module. The system adopts a fully functional device JN5139 Z01 - M02R1 as ZigBee network coordinator to receive instructions from upper machine and send information back to the machine. Three simplified function equipments JN5139 Z01 - M01R1 are adopted as a network node to control home equipments and upload information. The whole work is operating in a star network structure.

The etwork layer supports RS232, RS485, ZigBee, WIFI, Internet and mobile communication network etc. ZigBee and WIFI can connect home appliances with the monitoring center. The mobile communication network can connect users with the monitoring center. Mobile phone users can be connected to the smart household system by the mobile communication network such as 2 G, 2.5 G and 3 G technology.

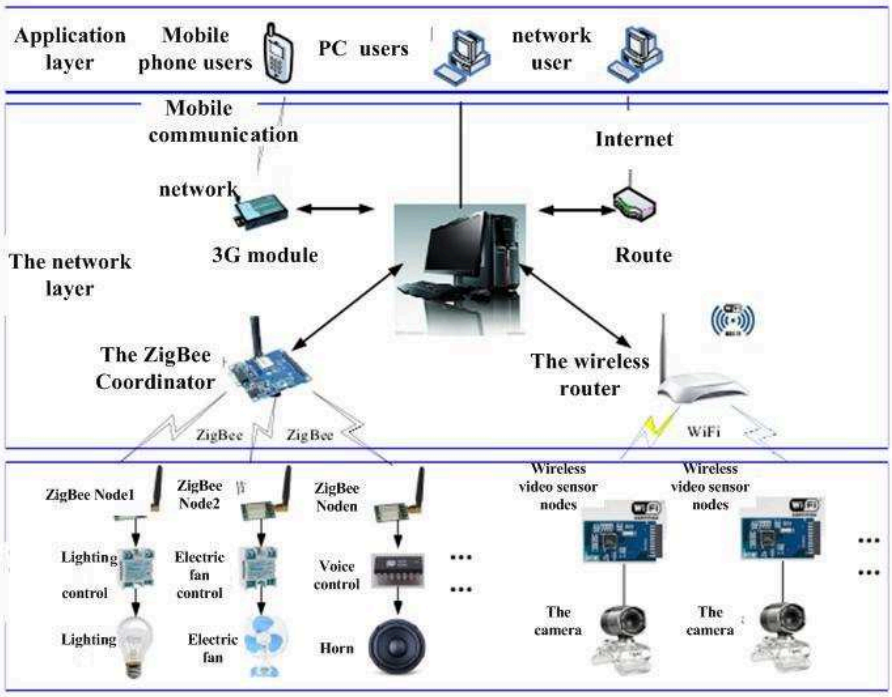

Figure 1 Overall Framework of the Monitoring System

Considering the expansion needs, this thesis chooses 3 G technology. 3 G module selects the Huawei EM560 module, which supports TD-SCDMA(3G) and GSM(2G) , a only TD module that supports both A frequency band (1880-1920 MHZ) and B frequency (2010-2025 MHZ) in the present world. EM560 supports mini PCI Express and UART serial port and functions such as text messaging, voice, the phone book, supplementary services, etc. With the center of the master machine, this thesis designs a ZigBee coordinator responsible for the node communication with ZigBee home appliances, a wireless video acquisition center to communicate with WIFI cameras and provide text messaging service to monitor home appliances with 3G modules.

2. Design of Hardware of Smart Household Monitoring System

This household monitoring system based on IOT in this thesis adopts the ZigBee star network, the household monitoring system uses JN5139 chip ZigBee star network. The household monitoring system ZigBee wireless coordinator provides a network for home wireless network and family network. ZigBee coordinator is aimed to start and maintain wireless network, connect with home PC through serial ports, receive and process commands from family gateways, send command data frame to the terminal node of ZigBee and receive and process data to familiy gateways through serial ports. More details can be seen in Figure 2.

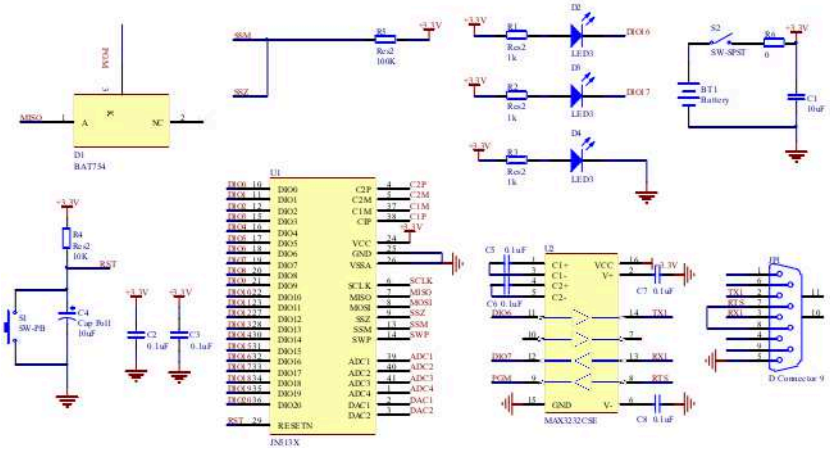

Figure 2 Schematic Circuit Diagram of ZigBee Wireless Coordinator

Schematic Circuit Diagram of ZigBee Wireless Terminal Nodes in this paper is shown in Figure 3. As ZigBee wireless terminal nodes exist in a wireless manner, there are not extra wired network serial ports in those nodes. In order to ensure home appliances under small signal control and high voltage, wireless terminal nodes need corresponding household control circuit. To better know household environment conditions, the corresponding intelligent temperature sensor DS18B20 collecting circuit is added. As ZigBee wireless terminal nodes and ZigBee wireless coordinator both use the same control kernel, thus batteries are also used in wireless terminal nodes. This system is compatible with the IEEE 802.11 b/g and allows interoperability among multiple vendors. It also supports Wi-Fi access protection, 802.11 I safety standards through the implementation of WEP security mechanism under AES/TKIP, 802.11 e quality of service (QoS). More details are introduced in Figure 4.

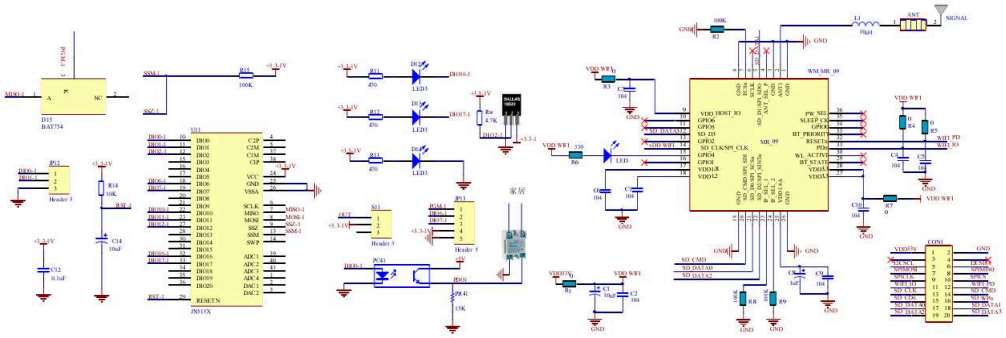

Figure 3 Schematic Circuit Diagram of ZigBee Wireless Terminal Nodes
Figure 4 Schematic Circuit Diagram of WIFI Video Receiving and Sending

Design of Software of Smart Household Monitoring System

The master software is developed by C# language in Visual Studio 2008 environment. Visual Studio is the most popular Windows platform development environment of Microsoft's that supports Visual Basic, Visual C# and Visual C++ development language, etc. The working process of the system control center is shown in Figure 5.

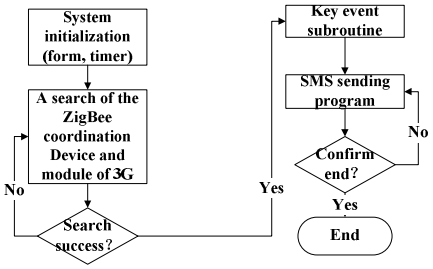

Figure 5 Working Process of Master Software

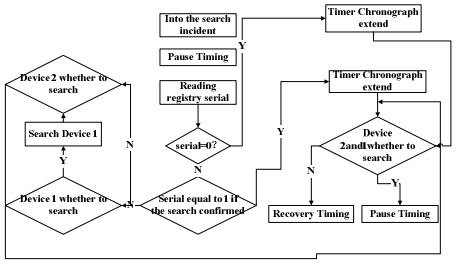

Figure 6 Automatic search algorithm

The master software and the ZigBee coordinator are connected with serial ports and the NET platform provides SerialPort class operation serial ports. The main control software and the 3G module EM560 are connected with USB and the registry of the PC operating system will create a virtual serial port to control EM560 through commands. While operating SerialPort, users can firstly configurae PortName, BaudRate, Parity, DataBits and StopBits. Then open the serial port under the command of Open(), close the port with Close(), read the port with Read() and write the port with Write().The serial port only needs to use SerialPort. DataReceived event to adopt event trigger methods.

Another vital technology to program the master is software multithreaded programming. "Threaded" is named by the System. Threading. Set up with new (), start with the start (), suspend with sleep (), end with abort (). It is noticeable that calling abort () often causes System. Threading. Thread AbortException, which is a system of .Net. It usually occurs if users give forced termination to an operating thread. At that time, the method of "try…catch…"is needed. What's more, the thread in the outside form can not get direct access to the form object but needs to used the method of delegate. It is

an important method for thread communication. The automatic search algorithm is shown in Figure 4-5.

Testing and Application of Smart Household Monitoring System Based on Internet of Things

Put one SI4432 module in a room and the other SI4432 module in the second room to test whether two sides can keep communication. Change the distance of two modules (increasing transmission distance and numbers of the walls) if the communication can be kept. Test again until two sides can not keep normal communication. Test results are shown in table 1. With the results, it is obvious that SI4432 has enough communication distance, which is applicable to this thesis.

Table 1 Test for Indoor Wireless Communication Distance

The test conditions	The test results
1 wall, spacing of 5 m	Able to reliable communication
3 wall, spacing of 23 m	Able to reliable communication
8 wall, spacing of 75 m	Able to reliable communication
9 wall, spacing of 85 m	Can't reliable communication, loss of data

Monitor the sensor nodes through the monitoring software in the monitoring center. If the monitoring center can collect data of sensor nodes, the wireless communication can be achieved in that distance. Then extend the distance between nodes and the center. Test results are shown in table 2.

Table 2 Test for Indoor Wireless Communication Distance

The test conditions	The test results
Outdoor, stadia barrier-free, 50 m	Able to reliable communication
Outdoor, stadia barrier-free, 100 m	Able to reliable communication
Outdoor, stadia barrier-free, 300 m	Able to reliable communication
Outdoor, stadia barrier-free, 500 m	Able to reliable communication
Outdoor, stadia barrier-free, 1000 m	Able to reliable communication

The monitoring interface is shown in figure 4 and the data uploaded by the monitoring software will be transmitted into real-time temperatures display. After receiving the monitoring data uploaded by a node, the state light will be up indicating the active state. Data uploaded includes time of data collecting and will be displayed on the interface after analysis.

Conclusion

This thesis, supported by general technology of video monitoring of household items through computers and mobile phones, designs a household monitoring system based on Internet of Things. This household monitoring system mainly focuses on general technology of video monitoring and controlling of home appliances by computers and mobile phones. This thesis also offers new ideas to the application and development of the IOT monitoring and pragmatic application of integrating smart households and the IOT monitoring. There are still some limitations and further researches are needed. Works such as optimizing the interface, upgrading the working process of the household monitoring system and developing wireless termination controlling software needs to be finished.

GNS-based Simulation and Analysis of OSPFv2 Neighbor Authentication

Xiaohua Li [a], Renlong Zhang, Yujie Wang, Li Yang, Juan Nie, Quanyue Yang

School of Computer and Information Engineering, Beijing University of Agriculture, Beijing, China

[a] lixiaohua_bj@163.com

Keywords: OSPFv2; neighbor authentication; GNS; MD5

Abstract. Routing information release is a kind of promise from the router for network reachability. Illegal routing information may have disastrous effects on the normal work of the network. Open Shortest Path First (OSPF) protocol provides authentication methods to protect the authenticity and integrity of the routing traffic. This paper describes two authentication types of OSPFv2, analyzes the realization mechanism and packet header format of each authentication respectively. Based on GNS3, a typical network topology was designed, and with the aid of it functional verification and security analysis are carried out. The simulation can provide a reference for building an OSPF network. Experimental results show that the configuration of OSPFv2 routing authentication can effectively prevent the router from receiving unauthorized or malicious routing updates, thereby improving network safety.

1.Introduction

To feasibly protect the authenticity and integrity of the routing traffic and provide the means to verify the authority of the participating routers, Open Shortest Path First protocol version 2 [1-3] (OSPFv2) supports two types of authentication. In this paper, we focus on the simulation and analysis of OSPFv2 routing authentication. We discuss the two authentication types of OSPFv2 in section 2, and carry out GNS-based simulation and analysis in section 3. Finally conclusions are given.

2.OSPFv2 Authentication

OSPFv2 supports two types of authentication [3-5]: one is simple password authentication and the other is MD5 cryptographic authentication. The authentication type is configurable on a per-interface basis and the 2-byte authentication type field (*AuthType*) in the OSPFv2 packet header should be set accordingly. Different type of authentication has different packet header format and realization principle. We will discuss it in the following.

2.1. Simple Password Authentication

In simple password authentication, the *AuthType* field in the OSPFv2 packet header (shown in Fig. 1) should be set to 1. At the same time, a 64-bit clear text password can be configured and all packets sent on a particular network must have this configured value in their OSPFv2 header. The received OSPFv2 packets will be authenticated according to the following rules. Packets which fail authentication will be discarded.

- The *AuthType* field in the received OSPFv2 packet header should match the setting of *AuthType* for the receiving OSPFv2 interface.
- The 64-bit *authentication* field in the received OSPFv2 packet header must be equal to the 64-bit password (i.e., *authentication* key) that has been configured for the interface.

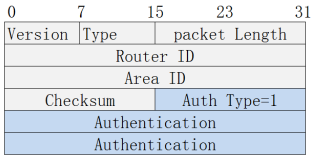

Figure 1. OSPF packet header in simple password authentication.

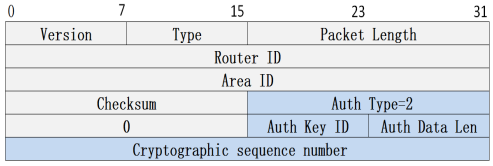

Figure 2. OSPF packet header in MD5 authentication.

2.2. MD5 Cryptographic Authentication

In MD5 cryptographic authentication, the *AuthType* field in the OSPFv2 packet header should be set to 2. In addition, the 64-bit *Authentication* field in the standard OSPFv2 packet header is redefined as shown in Fig. 2 and a 64-byte *crypto authentication TLV* (message digest) will be appended to the OSPFv2 packet as well. The new field definitions are as follows:

- *Key ID*: This field identifies the algorithm and secret key used to create the message digest appended to the OSPFv2 packet. Key Identifiers are unique per-interface (or equivalently, per-subnet).
- *Auth Data Len*: The length in bytes of the message digest appended to the OSPFv2 packet.
- *Cryptographic sequence number*: An unsigned 32-bit non-decreasing sequence number. Used to guard against replay attacks.

The received OSPFv2 packets will be authenticated according to the following rules. Packets which fail authentication will be discarded.

- Locate the receiving interface's configured key having *Key ID* equal to that specified in the received OSPFv2 packet. If the key is not found, or if the key is not valid for reception, the OSPFv2 packet is discarded.
- If the *cryptographic sequence number* found in the OSPFv2 header is less than the *cryptographic sequence number* recorded in the sending neighbor's data structure, the OSPFv2 packet is discarded.
- Verify the appended message digest. Calculate a new digest and let it compare with the received one. If they do not match, the OSPFv2 packet is discarded. If they do match, the OSPFv2 protocol packet is accepted as authentic.

3. Simulations and Analysis

In this section, a typical network topology is designed and with the aid of GNS3, we carry out simulation and analysis. GNS (Graphical Network Simulator) is a very good graphical network simulator that can simulate the real IOS and complex networks. It is visual and accurate, with friendly interface, convenient operation, and strong interactivity. It can be said to be one of the most popular network simulators. It is also an excellent complementary tool to real labs for network engineers, administrators etc. It is an open source, free program that may be used on multiple operating systems, including Windows, Linux, and MacOS X.

3.1. Experimental Network Topology and Configurations

We design such a network topology as shown in Fig. 3, which is a two-level hierarchical routing scheme. It consists of three areas and 10 C7200 routers. Through serial and fastEthernet connections the routers are connected and compose a typical LAN network. In this topology, R3 and R2 are *Area Border Routers*: through R3 area 0 and area 2 is connected, whereas area 0 and area 1 is connected through R2. The *router ID* and other corresponding configurations for each router are set and marked in the figure.

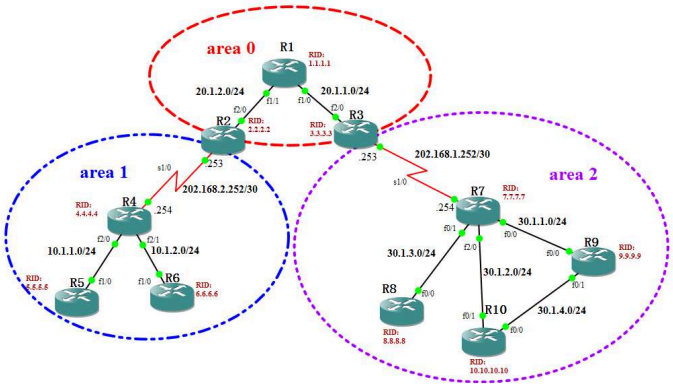

Figure 3. Experimental network topology.

3.2. Simulation and Analysis of Simple Password Authentication

Router R3 and R7 are connected through serial connection. We will enable simple password authentication to this connection and capture the data packets on this route using Wireshark software. We will unpack and analyze the captured packets to discuss the behaviour of OSPFv2 and analyze the security of OSPFv2 authentication.

By default, OSPFv2 employs *Null* authentication, meaning that all the routing exchanges over the network/subnet are not authenticated. In this case, when R3 and R7 runs, after sending *hello* messages periodically in the network, they can find each other as their neighboring router, establish full adjacency and synchronization with each other. Fig. 4 demonstrates the packet series for database synchronization in OSPFv2 *Null* authentication. From this series of operation, R3 can learn the routes in area 2 from R7, thus, all the routers in the topology can *Ping* and communicate with each other. When simple password authentication is configured on R7, as for the mismatch authentication type, the neighbor relationship between R3 and R7 is broken. Examine the neighbor list of R3, we find that only R1 is the neighbor of R3.The topology at this time becomes isolated and routers in area 2 cannot communicate with other routers in area 0 and area 1. But if we set the same password and enable simple password authentication on R3, we can see the full adjacency between R3 and R7 is established again (shown in Fig. 5).

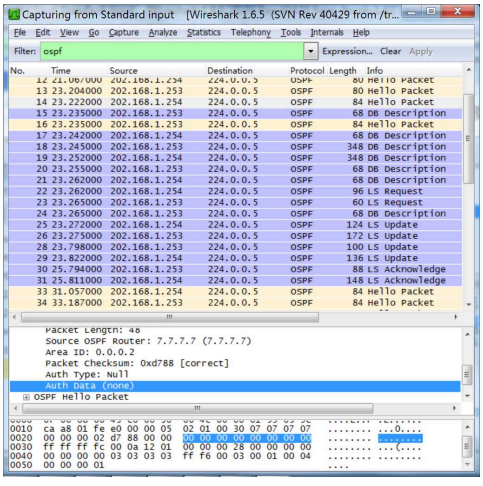

Figure 4. Database synchronization in OSPF Null authentication.

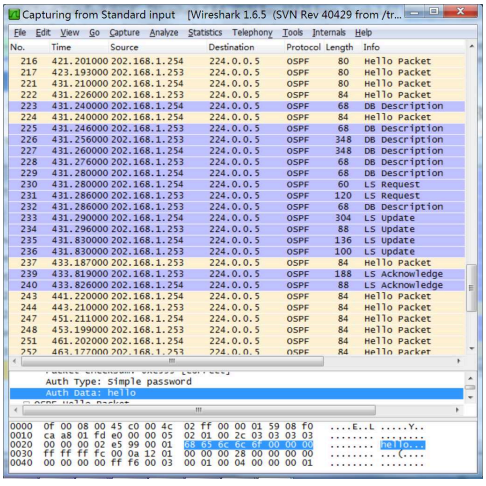

Figure 5. Database synchronization in OSPF simple password authentication.

Examine the neighbor list and route table of R3 (shown in Fig. 6), we can see R7 becomes its full adjacent neighbor and R3's route table is complete and convergent.

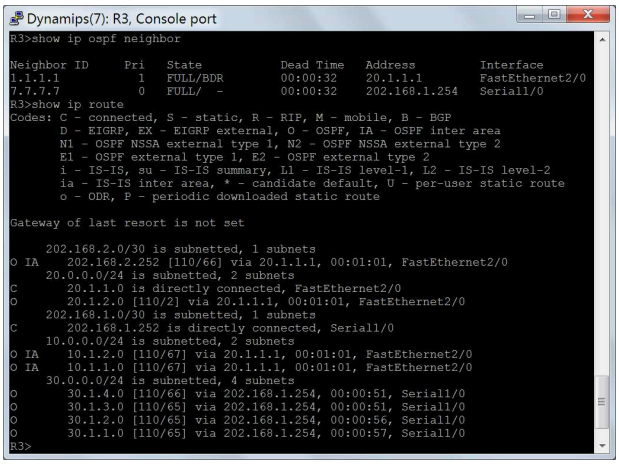

Figure 6. Route table of R3 in simple password authentication.

3.3. Simulation and Analysis of MD5 Cryptographic Authentication

We will enable *MD5 cryptographic authentication* to the serial connection between R2 and R4. By default, OSPFv2 employs *Null* authentication. In this case, after sending *hello* messages periodically in the network, R2 and R4 can find each other as their neighboring router. After the establishment of full adjacency, their link state databases are synchronized. When *MD5 cryptographic authentication* is configured on R2, packet series captured using *Wireshark* (shown in Fig.7) demonstrate that the neighbor relationship between the two routers is broken due to the mismatch of authentication type, but when we enable MD5 cryptographic authentication on R4, full adjacency and synchronization between the two routers is established again (shown in Fig. 8).

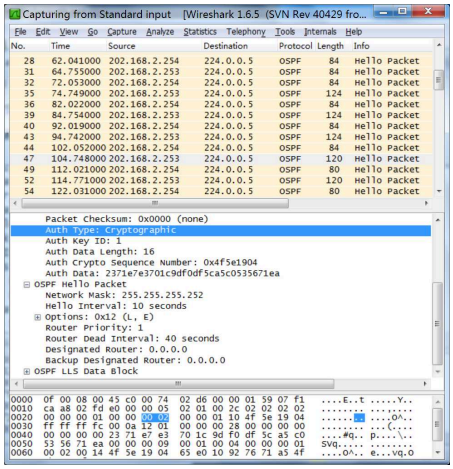

Figure 7. Neighbor relationship breaks in MD5 cryptographic authentication.

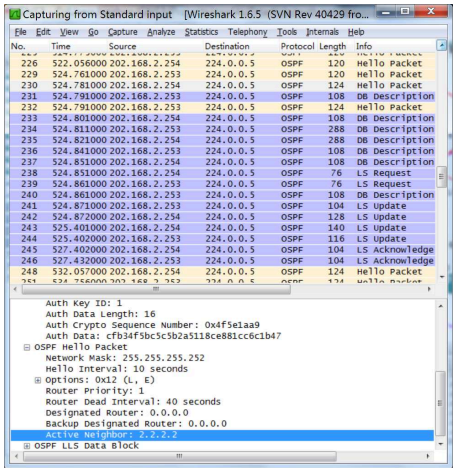

Figure 8. Establishment of full adjacency in MD5 cryptographic authentication.

Examine the route tables of R4 (shown in Fig. 9), we can see it is complete and convergent.

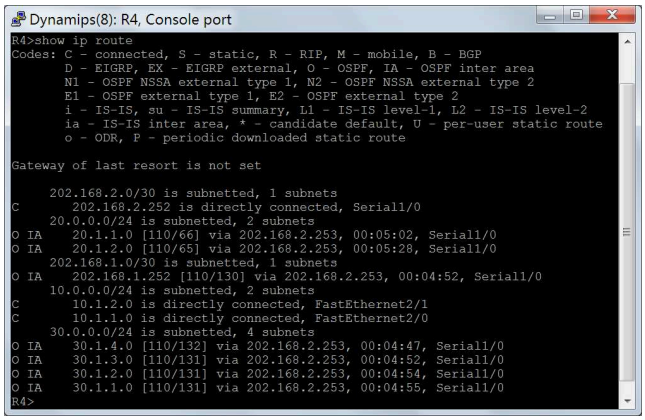

Figure 9. R4's Route table in MD5 authentication.

Summary

This paper makes a study of OSPFv2 neighbor routing authentication, analyzes the realization mechanisms and packet header formats of the simple password and MD5 cryptographic authentication. Based on GNS, simulation and analysis are carried out. Experimental results show that the configuration of the OSPFv2 neighbor routing authentication can prevent the router from receiving unauthorized or malicious routing updates, thereby improving network safety. Using Wireshark to capture OSPFv2 packets and analyze the security of OSPFv2 authentication, we can see simple password authentication can guard against routers inadvertently joining the routing domain, but it is vulnerable to passive attacks. Anyone with physical access to the network can learn the password. MD5 cryptographic authentication is much safer than simple password authentication. It can prevent eavesdropping on the line to obtain the authentication key phenomenon effectively.

Study on the Design of Mobile Digital Library based on 3G Mobile Internet Technology

Jing Zhao

Library, Handan College, Handan, 056005, China

Keywords: 3G technology; Mobile library; VC software; MATLAB software; Hierarchy analysis; Data mining

Abstract. We use hierarchical data mining to compress the mobile communication data, which improves data transmission rate of 3G mobile internet. Based on this, combining the advantages of VC and MATLAB, we design the digital library architecture of 3G mobile internet model. This model has the functions of inquiry, backstage management, and mobile data optimization and so on. In order to verify the effectiveness and reliability of the model, we use network testing of small digital library as an example to test the library query function with mobile phone. By using the Android test terminal we get the library query process curve and the data flow transmission characteristics. It provides technical support for 3G on mobile internet technology and innovative design of library.

Introduction

With the development of the 3G mobile internet technology, mobile internet is able to meet the digital library needs of text, pictures, video and audio transmission [1, 2]. But in the design process of the mobile digital library it will produce a lot of data redundancy, so it needs to compress the data, so as to reduce the packet loss rate and delay characteristics of files, and improve the data transmission rate. In this paper we use hierarchy analysis process to do mining on the transmission data, and use conversion functions of HTML and WML to establish the mobile internet platform, and eventually develop WTA mobile library based on Android intelligent terminal, which is an innovation application of computer and communication technology.

Research on Application of 3G Mobile Internet in the Construction of Digital Library

With the popularization of 3G mobile internet technology, mobile technology is applied in mobile phone terminal and portable terminal device [3]. We use the protocols of WML and HTML to design mobile network and establish a digital library model, as shown in Figure 1.

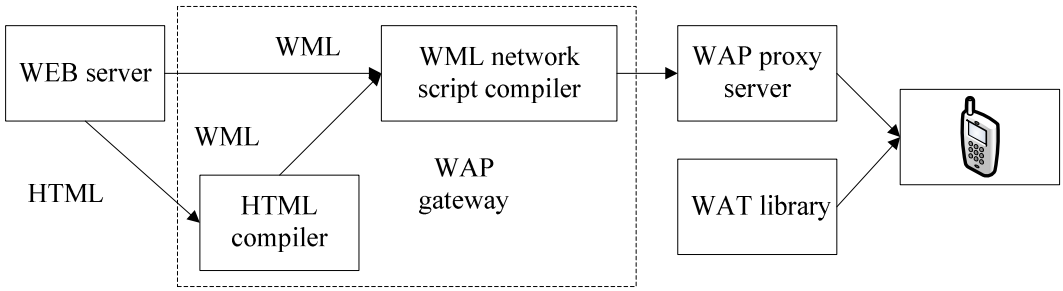

Fig. 1 Digital library mobile network model

Figure 1 shows the digital library by using HTML protocol and WML technology, and it realizes the data conversion between protocols [4]. The library can use WAP gateway to establish mobile network terminal of WEB server, and also use WAP proxy server to realize the request and authentication of mobile terminal, which ensures the stability and reliability of the network.Figure 2 shows the architecture diagram of 3G mobile digital library [5]. As shown in the diagram, it uses 3G mobile network access stations to connect many devices, including 3G mobile phone, 3G portable computer and 3G internet terminals.

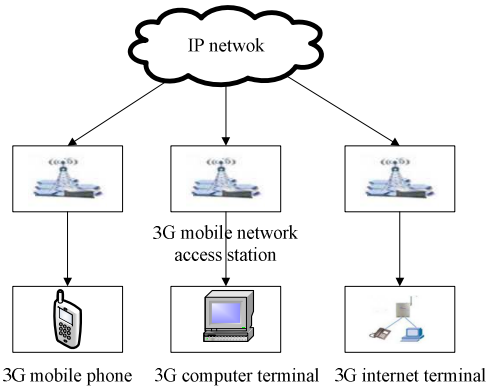

Fig. 2 Architecture diagram of 3G mobile digital library

Mathematical Model and Algorithm Design of Mobile Digital Library based on Data Compression Technology

In the constructing process of 3G mobile digital library, due to limitations of mobile communication hardware, it needs to compress the transmission data [6, 7]. We use the hierarchical data mining to compress the mobile communication data. Assume that the initial inputting sequence is $M, C1, C2$, so:

$$\{K_{M,m}\}, -C1 < m < -C2. \tag{1}$$

Compression of 3G mobile data can be expressed as shown in formula (2).

$$\begin{aligned} x_{m,\frac{n}{2}} &= \sum_{i=-M+n}^{n} b_{i-n}, d_{m+1,i} \\ y_{m,\frac{n}{2}} &= \sum_{i=-M+n}^{n} u_{i-n}, d_{m+1,i} \end{aligned}. \tag{2}$$

In order to improve the data compression quality, we use hierarchy method to analyze the data, as shown in formula (3).

$$f_{o,p}^{(n)} = f_{o,p}^{(n-1)} - [\sum_{o} u_{o,p+1}^{(n)} G_p^{(n)} + \frac{1}{2}]. \tag{3}$$

G_p is the lift coefficient of B/S frame data algorithm. According to the level compression model, the data compression can be written in formula (4).

$$\begin{array}{l} G_{p1}^{\ i} \quad \ldots \quad G_{p\,n/2i}^{\ i} \\ \quad \ldots \\ G_{p1}^{\ 2} \quad \ldots \quad \ldots \quad G_{p\,n/2i}^{\ 2} \\ G_{p1}^{\ 2} \quad G_{p2}^{\ 2} \quad \ldots\ldots\ldots \quad G_{pn}^{\ 1} \\ \Rightarrow \quad \Rightarrow \quad \Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow\Rightarrow. \\ S1 \quad S2 \quad \ldots\ldots \quad \ldots \quad \ldots\ldots \quad \ldots\ldots \quad S_n \end{array} \tag{4}$$

S is the level and number of calculation. In order to realize the data compression process, we use VC and MATLAB joint programming way to control level compression model. The main program is as follows:

```
#include <stdio.h>
void main()
{Again:
{    int large(int x,int y);
     int a[10],b[10],i,n=0,m=0,k=0;
     printf("\n starting:\n mobile library a:\n");
     for(i=0;i<10;i++)
          scanf("%d",&a[i]);
     printf("\n search directory b:\n");
```

```
for(i=0;i<10;i++)                                    else
        scanf("%d",&b[i]);                                  if (large(a[i],b[i])==0)
printf("\n");                                                       m=m+1;
for(i=0;i<10;i++)                                           else
{if (large(a[i],b[i])==1)                       k=k+1;}
                n=n+1;
```

Research on Application of 3G Technology in Digital Library Construction

In order to verify the effectiveness and reliability of multi hierarchical analysis model designed in the second part, based on the WCDMA single carrier bandwidth, we use the MATLAB platform to do simulation calculation on the test data [8, 9]. The MATLAB interface is as shown in Figure 3.

Fig. 3 MATLAB interface

In this paper, we use the Matlab2011 version as the numerical calculation and the Custom version. We use the Fdatool tool to design the original peak signal in MATLAB, and test the transmission process of the signal, as shown in Figure 4.

Figure 4 shows the test schematic diagram of 3G signal transmission using MATLAB software. The Structure uses the Direct-Form model, order selects 255. Using 3G base station as a signal source, we can obtain visualization curve of signal transmission process.

Table 1. Data transmission testing table of digital library

Data type	Transmission time (s)	Transmission speed (kb/s)	Packet loss rate (%)
Original data	15.8	12.5	2.5
Compression data	11.5	24.6	1.2

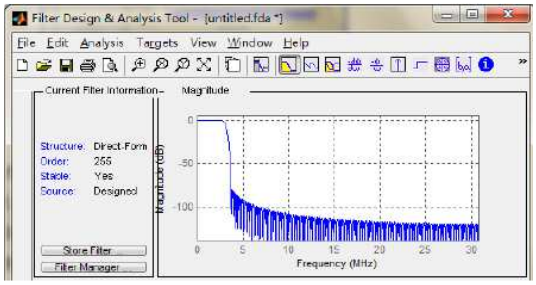

Fig. 4 MATLAB data signal transmission test

Table 1 shows the data transmission testing table of digital library by using Android intelligent terminal. From it we can see, the video compression algorithm can improve the data transmission speed, reduce the packet loss rate and improve the delay performance of data.

Figure 5 shows the query process curve of mobile digital library.We use the Android intelligent terminal to realize data transmission and visual interface [11]. From the chart we can see, when the query produces results, the data transmission amount is relatively large, and the entire query process curve is relatively smooth, which meets the design requirements.

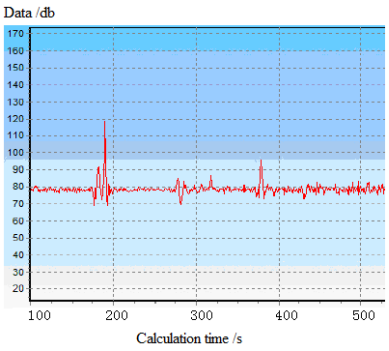

Fig. 5 Data transmission curve of Android intelligent terminal

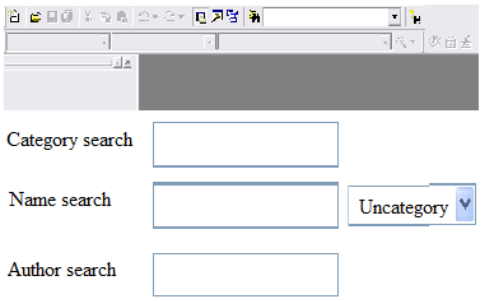

Fig. 6 Interface diagram of 3G digital library

Figure 6 shows a schematic diagram of 3G digital library using VC and MATLAB [12]. According to the user demand, using characteristics of Android intelligent terminal, users can access the literature of 3G digital library from three aspects of category, name and the author, which improves the efficiency of literature search.

Summary

In this paper we establish a mathematical model of 3G mobile internet digital library, and use multi hierarchy data mining technology to improve the model, which improves the signal transmission speed, improves the signal delay and achieves the design process of digital mobile library. We use VC and MATLAB joint programming control to establish 3G mobile internet digital library model, which realizes the function of digital library inquiry, backstage management and mobile data optimization. We use the Android intelligent terminal to test the performance of library. Through the results we find that the data transmission process of digital mobile library designed in this paper is steady, fast running speed, which can meet the needs of different users.

Research on Key Technology of Web Network based on Mobile Computing

Rong Deng

Institute of Information Engineering, Chongqing Institute of Engineering, Chongqing, 400037, China

Keywords: Mobile computing; Web network; VC software; Network node; Spatial statistics; 3G base station

Abstract. Mobile computing environment is relatively complex, and the structure dynamic degree is high, and the heterogeneous is changeable. Therefore, the development of mobile network based on web techniques must be adapted to the complex environment. In order to get a better network structure supporting mobile computing, based on the context aware consciousness theory, combined with the VC programming software, we design the algorithm of mobile computing network node, obtain the spatial statistical node model of mobile network, and use GPRS/3G base station to establish mobile network model based on the core of multimedia services. In order to verify the effectiveness and reliability of mobile computing algorithm, we calculate the network performance using VC programming software, obtain the network data transmission and delay results, and use mobile algorithm to develop multimedia licensing scheme. It provides a new algorithm for researching on mobile computing.

Introduction

Due to the rapid development of wireless communication facilities and continuous expansion of mobile devices, mobile computing has rapid development as a new network computing technology[1,2]. Mobile computing access information on the moving, and it can coordinate distributed work and spread the field of distributed computing [3, 4]. The running network node has characteristics of space free moving, so that it makes network environment complicated. Combined with context awareness learning principle, we design the Web engine and network components. The framework structure is as shown in Figure 1.

Figure 1 shows schematic diagram of mobile computing Web engine design. From the chart we can see, the design of network is mainly based on the awareness learning theory. The main part of the network is composed by the Web engine, conscious learning and context aware component. Between Web engine and every member there is a great relationship [5]. In order to synergy mobile knowledge base, we need to optimize the design of network nodes, and coordinate performance of each component in space domain.

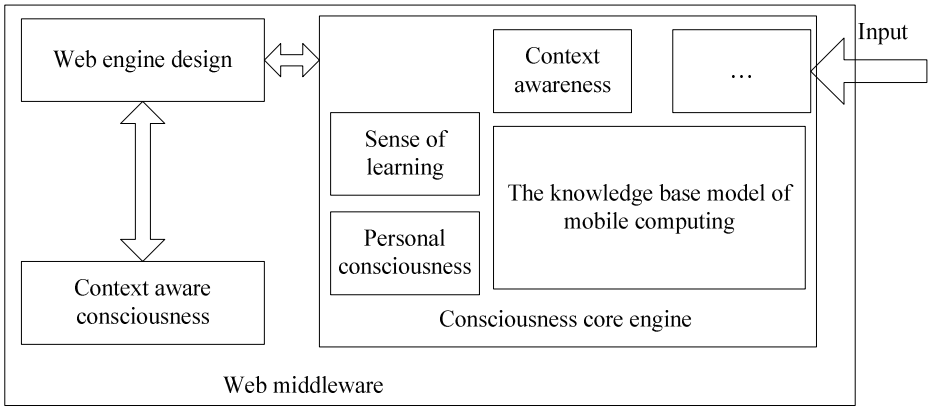

Fig. 1 Schematic diagram of mobile computing Web engine design

Mathematical Model and Algorithm Design of Mobile Computing Web Network

The primary basis for the design of mobile web network is optimization of network nodes. The node optimization can speed up the mobile computing speed, which realizes the effective transmission of information. We use the spatial statistical analysis of Web node as base, assume that the space matrix of mobile computing network node is Q, and the matrix is symmetric [6, 7]. The n-dimensional proximity relation of mobile web space can also be expressed with matrix, in order to simplify the calculation; the formula is as shown in formula (1).

$$Q=\begin{bmatrix} q_{11} & q_{12} & \cdots & q_{1n} \\ q_{21} & q_{22} & \cdots & q_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ q_{n1} & q_{n2} & \cdots & q_{nn} \end{bmatrix}. \tag{1}$$

q_{ij} is network space adjacent relation between node i and node j . If x_i is reference values of position i, so similarity between nodes can be represented as shown in formula (2).

$$I=\frac{n\sum_{i=1}^{n}\sum_{j=1}^{n}q_{ij}(x_i-\bar{x})(x_j-\bar{x})}{\sum_{i=1}^{n}\sum_{j=1}^{n}q_{ij}\sum_{i=1}^{n}(x_i-\bar{x})^2} =\frac{\sum_{i=1}^{n}\sum_{j\neq i}^{n}q_{ij}(x_i-\bar{x})(x_j-\bar{x})}{S^2\sum_{i=1}^{n}\sum_{j\neq i}^{n}q_{ij}}. \tag{2}$$

S is the variance of node displacement distance, and the formula is as shown in formula (3).

$$S^2=\frac{1}{n}\sum_{i}(x_i-\bar{x})^2. \tag{3}$$

$\bar{x}$ is the average value of node distance, and the formula is as follows:

$$\bar{x}=\frac{1}{n}\sum_{i=1}^{n}x_i. \tag{4}$$

We introduce the optimization parameters to represent the optimization performance of clustering, and its expression is as shown in formula (5).

$$Y=\frac{(n-1)\sum_{i=1}^{n}\sum_{j=1}^{n}w_{ij}(x_i-x_j)^2}{2\sum_{i=1}^{n}\sum_{j=1}^{n}w_{ij}\sum_{i=1}^{n}(x_i-\bar{x})^2}. \tag{5}$$

In order to realize the optimization mathematical model of web network mobile computing, we use VC programming to design the algorithm. The main program is as follows:

```
#include <stdio.h>
#include <math.h>
void main(){Again:{
int rand(void);int max_valud;int a[4][4];int m,n,restart;
    printf("\n start:\nWeb mobile computing array:\n")
    for (m=0;m<4;m++)
        for (n=0;n<4;n++)
```

```
            {if (n=0) printf("\n");
                    a[m][n]=rand();
                    printf(" %5d",a[m][n]);}
        scanf("%d",&restart);
        if (restart==1) goto Again;}}
    int max_value(int array[][4])
    {int i,j,max;max=array[0][0];
        for (i=0;i<4;i++)
            for (j=0;j<4;j++)
                if (array[i][j]>max)
                    max=array[i][j];
        return (max);
    }
```

The Design of Web Network Mobile Computing System

In order to verify the effectiveness and reliability of web mobile computing model and algorithm, we use multimedia web network as architecture model to verify the performance of mobile computing. The overall network structure is as shown in Figure 2.

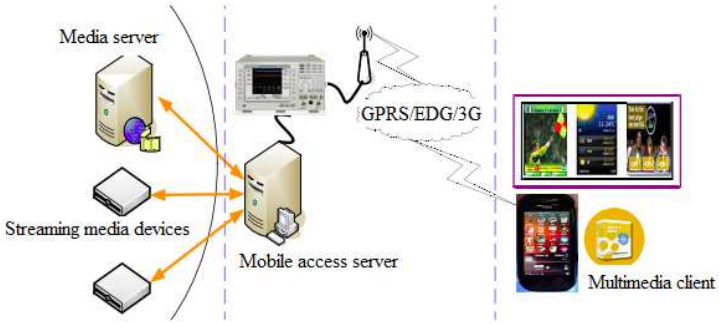

Fig. 2 Integration model of mobile computing web network

Figure 2 shows the architecture model of mobile calculation web network. In order to realize multimedia mobile service, the user can connect multimedia client by mobile phone, access multimedia network through the mobile server and the GPRS/3G base station [8]. The multimedia network terminal is composed of video and audio servers.

Figure 3 shows the test results of the web platform using VC software. The curve represents the sensitivity of the QoE on the QoS network. QoS parameters mainly include network delay, network packet loss rate and mobile call error rate and success rate [9]. For different mobile computing service, curve form is different. As shown in Figure 3, the curve has three relatively flat areas, which represents the QoE portion is not sensitive to QoS part.

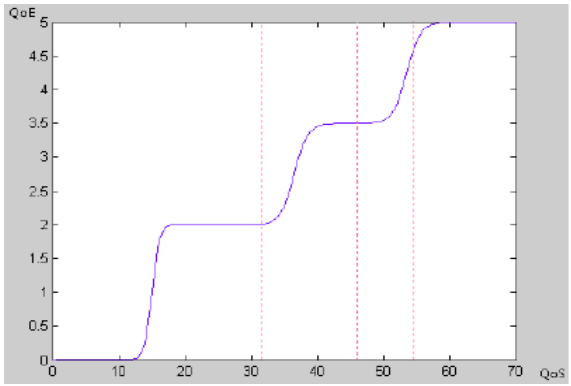

Fig. 3 The curve calculated by VC software

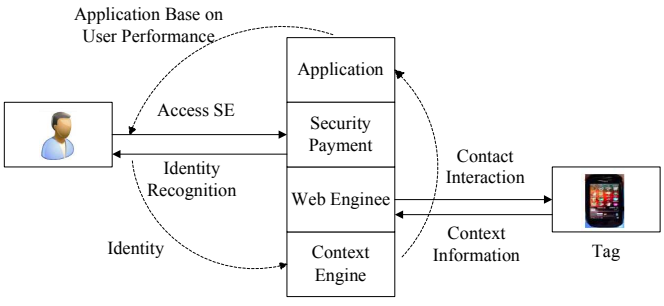

Fig. 4 The design of multimedia services mobile computing

Figure 4 shows the design of multimedia services mobile computing. According to the design in the scene graph, mobile user can get all kinds of services from the cinema, and can check all the information tags in the web page [10]. When the user enters the page and finds a poster, poster interior is embedded in NFC tag which can access webpage. When a mobile device selects it, it will respond to the corresponding information, and we can obtain film information from the label.

Fig. 5 Privacy protection technology of mobile video

Figure 5 shows schematic diagram of video protection using mobile computing network node. Video in the figure is transformed and applied the jamming technology. According to the context awareness principle, when the video decoding, video can be clear; when the video encryption, video will produce distortion effect.

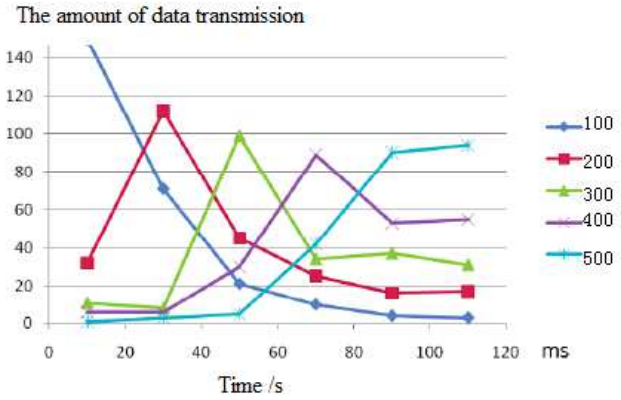

Fig. 5 Statistical graph of data transmission amount

Figure 5 shows data transmission amount and data search of web network engine in the mobile computing process. From the figure we can see, with the increasing of network node data, the data transmission amount will increase rapidly [11]. In order to study the influence of network nodes on data transmission, we list the network optimization, time delay characteristics and the comprehensive evaluation results in Table 1.

Table 1. Network node optimization table

Number of network node optimization	Delay characteristics (ms)	Comprehensive evaluation score
200	50.1	3
300	40.2	5
400	38.5	6
500	32.1	8

Table 1 shows the delay characteristics and comprehensive evaluation results through network nodes optimization. From the table we can see, as the increasing number of network node optimization, network delay reduces gradually, with lowest 32.1ms. Comprehensive evaluation score also increases with the increasing number of network node optimization [12]. So the design of network node optimization improves the performance of mobile computing, and optimizes the network architecture. It verifies the effectiveness and reliability of the network optimization model.

Summary

Through the improvement of mobile calculation environment, we propose a spatial web mobile internet node model, and use the matrix theory to establish the optimization mathematical model of node, and use VC programming software to design the algorithm. Using VC programming control method, combined with the GPRS/3G base station, we establish the mobile web internet architecture model of multimedia service, and develop multimedia licensing scheme. In order to verify the effectiveness and reliability of multimedia mobile internet architecture model, we use the VC visualization technology to statistics network data transmission and time delay characteristics. It provides the theory reference for the application of web technology in mobile computing.

Keywords: argumentation, E-commerce, negotiation, Jess

Abstract: Based on Dung's argumentation framework, using Dung's extended argumentation semantics, importing reasoning argument and fact argument, design and implementing Jess-based argumentative E-commerce system, the system has important significance and high reference value for studying E-commerce argumentative negotiation systems.

Introduction

At the end of 1980, researchers began to study E-commerce negotiation system; multi-agent technology is mainly adopted in the study of negotiation system, in which agent partly or wholly represents human negotiation. Intelligent E-commerce negotiation and argumentation-based negotiation theory has became one of the hotspots in artificial intelligence. Multi agent based negotiation refers to the interactive action between the agents who have conflict interests and have desire to corporate with each other in order to reach both accepted agreement in the limited resource and information[1].

In this paper we design and implement a negotiation algorithm based on E-commerce alternating negotiation applied in E-commerce negotiation. In the negotiation system agent will negotiate with the opposite side and present arguments to persuade the other to accept his proposals. In the end of the negotiation agents will reach agreement on a certain proposal or quit the negotiation without agreement. We use Jess language simulate negotiation process.

Argumentation theory

In the field of automatic negotiation field, there are three kinds of negotiation mechanism and method[2], game theory based, heuristic-based and argumentation-based negotiation. Argumentation based negotiation is one of the research hotspots in negotiation field.

Besides proposals argumentation based negotiation permits agents exchange extra information in the form of arguments to defend some behaviors by arguments, so as to dynamically affect other agent's attitude and knowledge. Argument has two basic functions, one is declaration of self negotiation position; the other is affect the other agent negotiating position.

Argumentation based negotiation framework

In 2003, Rahwan etc. presented a relatively comprehensive concept framework[3], and described argumentation based negotiation external factors and internal factors. According to the negotiation concept framework of Rahwan, we define proposal, argument, the functional relation between argument and proposal and the binary preference relations between agents as the internal elements of agent. We also specify the interactive environment: primitives and their meanings of interactive agent are defined; negotiation data is stored in working memory and we use fact base in the simulated program.

We define preference based argumentation framework. Supposing two agents, ag_i *and* ag_j correspondingly refer to negotiation agents. P represents the proposals set, and $P = \{P_1, P_2, ...P_n\}$. Assuming exists $P_c \in P$, in which P_c is preserve proposal and other proposals are preferred to P_c.In the proposal set P all the proposals are mutually exclusive.

Definition1 Abstract argumentation framework[4] is a binary relation $(Arg, attacks)$, Arg is the infinite set of arguments, $attacks \subseteq Arg \times Arg$ is the binary relation on Arg. Suppose $X, Y \subseteq Arg$, X attacks Y iff $x \in X$, $y \in Y$ and $(x, y) \in attacks$. $Args$ is the conclusion set of arguments and $Attack$ is the conflict set in logic.

Definition2 Argument extension set X is a set of arguments

i) X is an admissible set iff X does not attack itself and attacks every argument set Y which attacks X.

ii) X is a preferred set iff X is the maximum admissible set.

iii) X is a complete set iff X is admissible and for $\forall x \in X$, X attacks all the arguments which attack x.

iv) X is a grounded set iff X is minimum complete.

v) X is an ideal set iff X is admissible and is contained in arbitrary preferred set.

Argument type

Using logic language ξ to construct arguments set $Argu(\xi)$. We present two kinds of argument: reasoning argument and fact argument.

Definition3 Reasoning argument A_R support proposal trying to justify the proposal.

Definition4 Fact argument A_F represent agent's belief.

And the two kinds of arguments satisfy:

(1) $Argu(\xi) = A_R \cup A_F$

(2) $A_R \cap A_F = \varnothing$

Argument and function are function mapping relation. G is the function, which is a mapping from a proposal to its supporting arguments, i.e. $\forall P_i \in P, G(P_i) \subseteq A_R$ and $\forall P_x, P_y \in P, P_x \neq P_y$, $G(P_x) \cap G(P_y) = \varnothing$.

Argumentative negotiation protocol

Amgoud[5]etc. defined negotiation protocol: negotiation protocol is a set of rules to control dialogues between agents who have well active ability. In a negotiation round the proponent and opponent agent can defend its own arguments and attack the others arguments. Each round includes negotiation behaviors of the agents.

Definition5 Argumentative negotiation is a non-empty dialogue sequence $N = \{n, ..., r_n\}$ between two agents.

Primitives

In the negotiation process, agents propose and exchange argument by primitives.

Definition6 A primitive is defined as $B_{r,t}$ which is the behavior of the agent in r round and the first t times in this round.

There are also some function, such as $Primitive(B_{r,t})$ returns r round the first t times primitive; function $Agent(B_{r,t})$ returns r round the first t times negotiating agent; function $Argument(B_{r,t})$ returns the r round the first t times argument; function $Target(B_{r,t})$ returns r round the first t times primitive; function $check()$ update negotiation theory to decide whether agree the other or find a new argument to attack it; function $defend()$ defend own proposal when opponent returns Argue.

Protocol include interact agreement and dialogue rules which is a formal constrain of interactive agents.

Negotiation protocol

In the negotiation process, the proponent and opponent alternating propose their primitives. The proponent agent has primitive set $\{Offer, Argue, Agree, Exit, Pass\}$ and the opponent has primitive set $\{Argue, Refuse, Pass, Accept, Exit\}$.

The needed sets in the program (1) A_{rec} is the received argument set; (2) P_{off} is the proposed proposal; (3) Att_{use} is the used attack set.

Table 1. Communication primitives and their meanings

primitives	meanings
$Offer(ag_i, ag_j, \mathrm{P}_x, \mathrm{A}_R)$	The proponent propose Px and its reasoning argument A_R
$Argue(ag_i, ag_j, a, T\arg et)$	ag_i present argument a attack agent ag_j 's proposal or argument
$\mathrm{Re}\,fuse(ag_i, ag_j, \mathrm{P}_x)$	ag_i refuse ag_j 's proposal P_x
$Pass(ag_i, ag_j)$	ag_i say nothing
$Accept(ag_i, ag_j, P_x)$	ag_i accept ag_j proposal P_x
$Agree(ag_i, ag_j)$	ag_i agree with ag_j
$Exit(ag_i, ag_j)$	ag_i raise to exit the negotiation

Firstly, begin with $B_{1,1}$ and all the sets initiate to empty sets.

Secondly, computing their proposal sets respectively, then the proponent agent proposes. We define a variable mark, $mark = \{1,0\}$ when $mark = 1$ the proposal is proposed by him, or else $mark = 0$ the proposal is the opponent's. At the beginning $mark = 1$.

Then agent sends primitive Offer, and function $\mathrm{Pr}\,imitive(\ )$ captures its return value. According to the return value agent make decision for next step. The whole process depicted in figure 1.

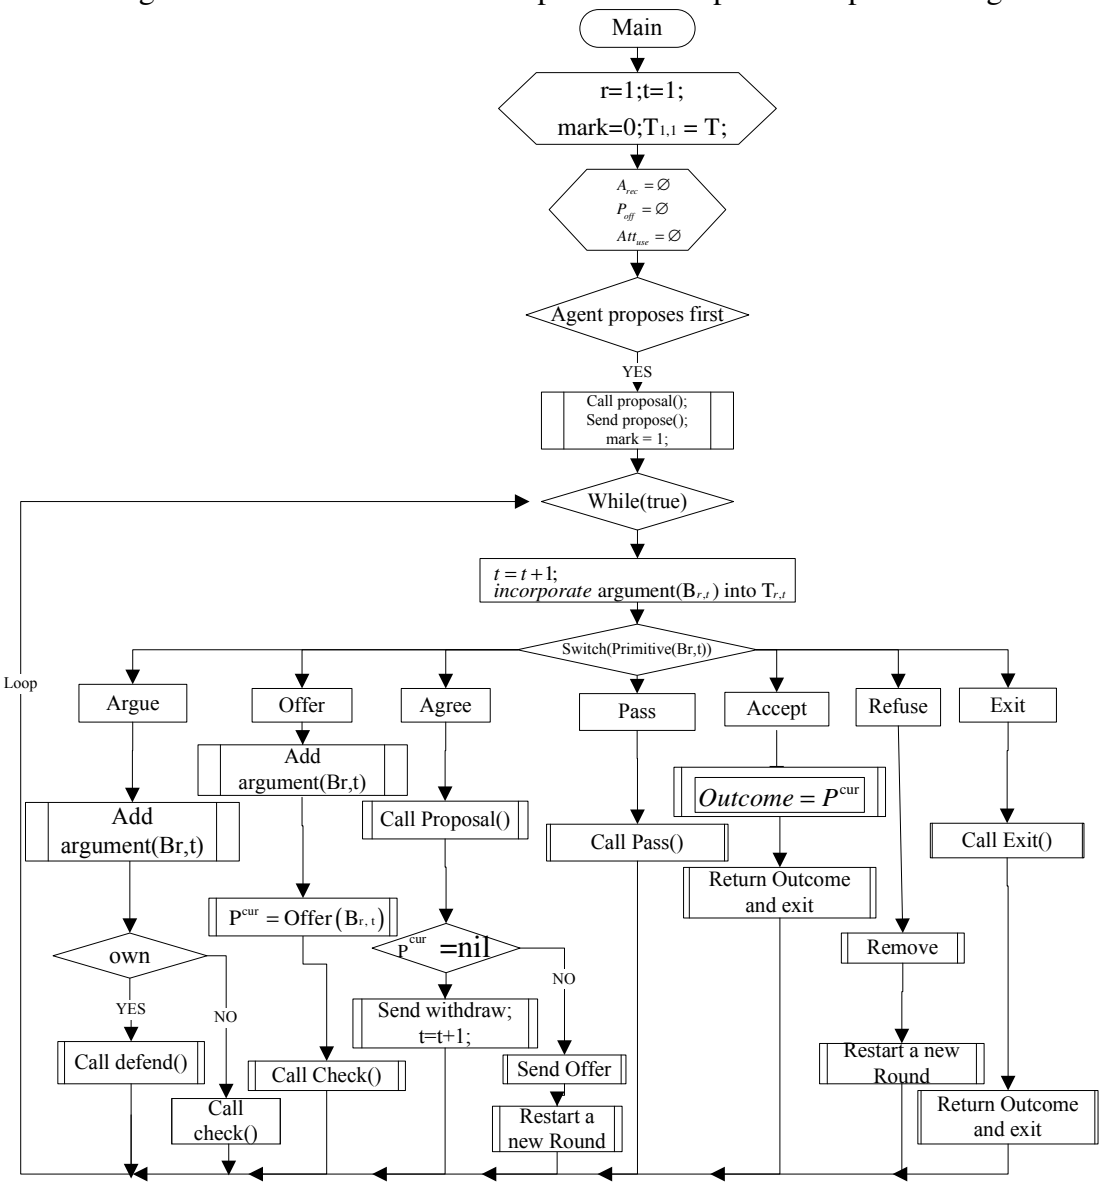

Fig.1. Negotiation main algorithm flow chart

Prototype design and implement

There are two main approaches: the structured approach and the abstract approach for argument implementation[6-7]. Jess is the kernel of expert system developed by Java. Java Expert System Shell is an extend rule engine based on Java platform. The prototype embedded Jess in Java, and we can create an example of Rete class as following: import jess.*; myrete = new Rete();

As depicted in figure 2, argument template and rules are defined ; output interface is displayed.

Argument template is defined as:

```
(deftemplate Ap (slot id) (multislot supportlist) (slot conclution))
(deftemplate Ae (slot id) (multislot supportlist) (slot conclution))
```

Rules are defined as::

```
(defrule compute-ESA-remove
(declare (salience 16))
(compute-esa yes)
(MAIN::Ap (conclution ?PH&:(not (myeq ?PH od))))
?tempESA <- (MAIN::ESA (offer ? PM&:
 ( myeq ?PH ?PL) ))=> (retract ?tempESA))
```

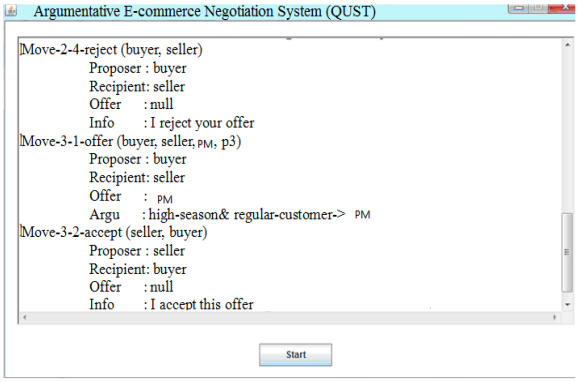

Fig.2. Argument template definition and output interface

Conclusion and discussion

Jess based e-commerce argumentative negotiation system is implemented; the prototype can process argument-based negotiation and output the proposals and arguments. Using argument easier to persuade the other agent accepts opinion and reach agreement. In the future we should use the knowledge base and belief base predict adverse belief and behavior and revision the agents' belief.

The Application Research of Information System in the Information Pipe

Huang Zhijun[1, a]

[1]Long communication service co. , ltd, Guangzhou 510507,China

[a] huangzhijun@yeah.net

Keywords: Information system; Information security risk management; Information pipe

Abstract. Applying the computer technology to the real management is the development trend of today's society. The popularization of computer technology has brought great convenience for managers. As a large application field of the computer, information system plays an important role in the information management. The application of information system in information management makes the spread of information and information utilization improved. This paper discusses related questions of information system in information management.

Research status of information security risk management method

Risk management is the overall process to identify, evaluate and control information system security risk, which includes risk identification, risk analysis, security selection, implementation and test security, security evaluation and so on.

ISO 13335 gives safety management relational model taking risk as the core. It assumes that the safety management of the main elements include assets, threats, vulnerabilities, and impact, risk, protective measures and residual risk; the main safety management process include risk analysis, risk management, safety awareness to maintain, monitor and consistency check; four risk management strategy risk avoidance, risk transfer, risk elimination are taken in the process of risk management to curb risk.

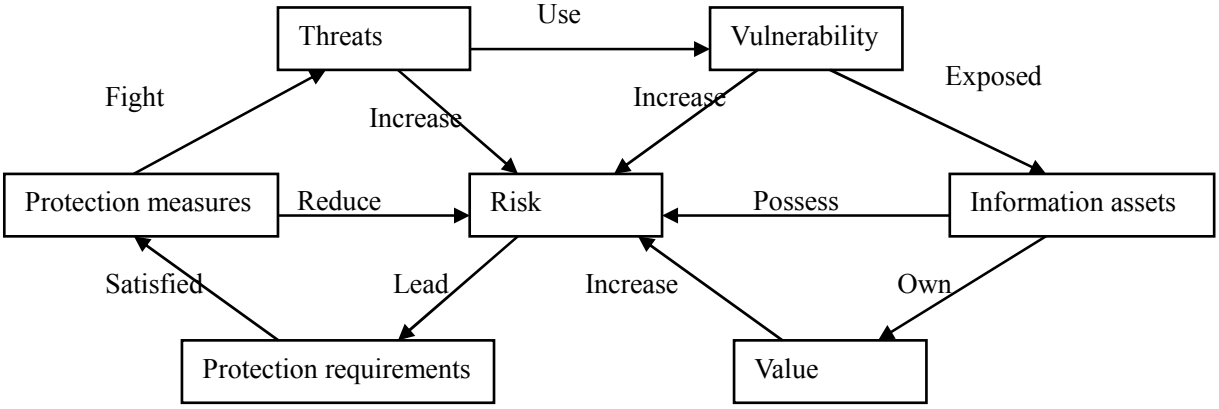

Figure1. Risk management relationship model diagram of ISO 13335

System security engineering capability maturity model SSE - CMM put forward by the United States at Carnegie Mellon university the defines four risk management process: PA04 - evaluation of security threats, PA05 - evaluation system vulnerabilities, PA02 - to assess impact of the event and PA03 - evaluation of security risks. [1] The relationship between them is shown in figure 2. It requires in the initial stages of information system security engineering, developers should first risk take analysis and assessment according to the risk management process.

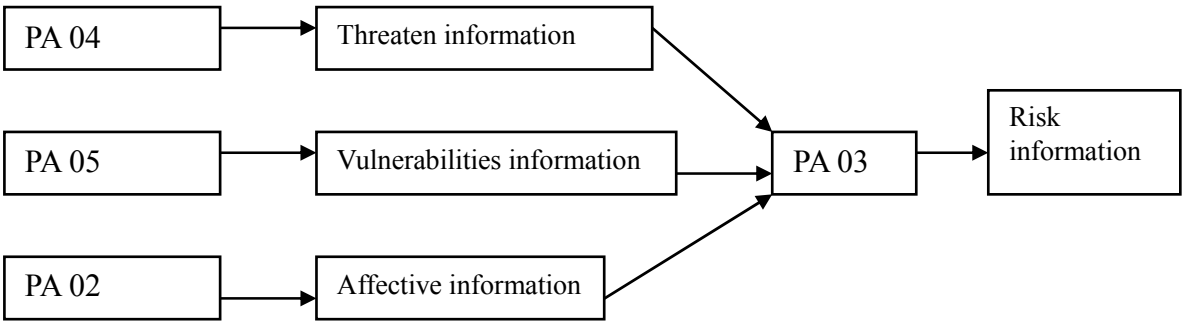

Figure2. Risk management process defined by SSE - CMM

Multilevel security model of information system

Security requirements

For important information system, the users have different level of security permissions. Information stored, processed and transferred in the system is of different level of sensitive and part of the equipment for processing the information also has the sensitive of different level. Therefore, realize the multilevel security is the basis of the information system requirements. [2] Multilevel security refers to the information system can allows users to access with different level of security permissions to have information of different sensitive level, and also can prevent unauthorized users to access information.

A multi-level security information system must at least meet the following requirements:

(1) Conduct reliable identification and authentication to users on the system;

(2) Data is transferred safely on the communication network;

(3) Allow users of the different level of security permissions to access information of different sensitive level at the same time;

(4) Prevent users from accessing to unauthorized information;

(5) Share information with the appropriate user safely.

Basic security assumptions

In order to simplify the description of information system security model, before the establishment of the formal security model, we put forward the following basic assumptions:

(1) Information system has reliable identification and authentication mechanism;

(2) Information system can provide secure data transmission channel;

(3) All entities of information systems have comparable sensitivity level;

(4) All the entities of information system have a need-to-know category and a need-to-share category, but the need-to-know category and need-to-share category of the same object is no intersection;

(5) Information system has a single security management center. Security management center is credible and the security administrator can correctly distribute the subject and object in the information system security level through the security management center;

Model elements

(1) Entities: resources in the information system (processes, files, equipment, etc.) and users.

(2) Object: abstract network connection to information systems in other computer system resources, remembered as $O=\{O_1,O_2,...,O_m\}$. [3] Connection security level is equal to the connection of the security level of resources.

(3) Main body: users or equipment in the information system, remembered as $S=\{S_1,S_2,...,S_N\}$. Use two functions $sdr,rcr:O\to S$ to respectively connect the sender $sdr(O)$ and receiver $rcr(O)$.

(4) Level of security permissions: trust level of when access to confidential information.

(5) Confidential categories: the confidentiality level of information stored in the object.
Security permission levels and the classification show the sensitive level of the subject and object, respectively, $C=\{C_1,C_2,...,C_q\}, C_1>C_2>...>C_q, C$ as poset.

(6) Categories need to know: based on the Need-to-Know principle, it is noted as. $K=\{K_1,K_2,...,K_r\}$.

Categories need to know principle means unless subject is to complete certain operations that need to access the object, subject to access object is prohibited. The category set each subject can access is a category set power set. For example: there are three need to know categories: K_1, K_2, K_3, then the category collection subject can access is one of the following set: $\phi, \{K_1\}, \{K_2\}$, $\{K_3\}, \{K_1, K_2\}, \{K_1, K_3\}, \{K_2, K_3\}, \{K_1, K_2, K_3\}$.

(7) Need to share: access restrictions based on the Need-to-Share principle is remembered as $H=\{H_1,H_2,...,H_w\}$.

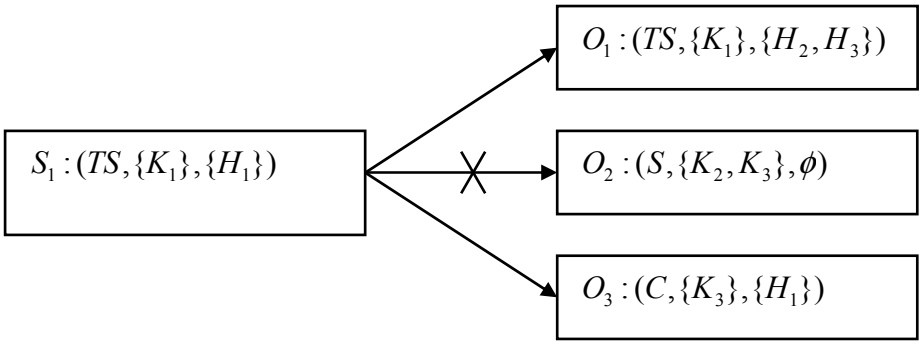

Figure3.An example of information sharing

Definition 1: In addition to have its own security permission $level(S)$, a body has two other levels of security permissions: the max security permission $v-\max(S)$ and minimum security permission level. The sensitive level scope of main body is $ran(S)=\{C: v-\max(S)\geq level(S)\geq a-\min(S)\}$.

Definition 2: Security level of subject S controls that of object O, if and only if

(i) $v-\max(S)\geq e-\max(O) and f_3(S)\supseteq f_4(O)$, or

(ii) $v-\max(S)\geq e-\max(O) and f_6\supseteq f_5(S)$

The domination relationship of subject to the object is $SL(S) dso SL(O)$.

Definition 3: Security level of object O controls that of subject S, if and only if

(i) $i-\min(O)\geq a-\min(S) and f_4(O)\supseteq f_3(S)$, or

(ii) $i-\min(O)\geq a-\min(S) and f_6(O)\supseteq f_5(S)$

Definition 4: Security level of Object O_1 controls that of subject O_2, if and only if $i-\min(O_1)\geq e-\max(O_2) and f_4(O_1)\supseteq f_4(O_2)$, remembered as $SL(O_1) doo SL(O_2)$.

Definition 2-6: Security level of subject S is equal to that of object O, if and only if

(i) $level(S)=level(O) and f_3(S)=f_4(O)$

(ii) $level(S)=level(O) and f_5(S)=f_6(O)$

The domination relationship of subject S to the object O is $SL(S)=SL(O)$.

Summary

The rapid development of computer technology and network technology accelerate and deepen the process of social informatization, also makes the organization and information system become

increasingly close. However at the same time of improving organizational information resources sharing and information systems business operation efficiency, it also brings information security problems. Therefore, as the basis of information system construction and safety management, a comprehensive and systematically information security risk management to organize information system has very important practical significance.

Keywords: information recommendation, push system, case-based reasoning.

Abstract. Information push systems play an important role in reducing information overload for people visiting online sites, but their services could be improved by using data from online social networks, electronic communication tools and others. Information push systems are used by electronic commerce sites to suggest products to their customers and to provide consumers with information to help them determine which products to buy. There are many electronic commerce applications on the Web. A common shortcoming is the lack of customer service and marketing analysis tools in most electronic commerce websites. The paper presents the information push system using case-based reasoning. It introduces the case-based reasoning technology and analyzes the case representation, case library and case search. Lastly, it gives the architecture of the information push system using case-based reasoning.

Introduction

With the rapid development of Internet technology, people want to find, collect and maintain their information need to spend a lot of time and energy from Internet. Traditionally, there are many methods of WWW information retrieval. The first is accessed through the web site address; the second is to use multiple search engine queries; third is the production of the professional company database query database. The traditional information retrieval technology has certain insufficiency. Firstly, the user must take the form of keywords summed up their information requirements. Secondly, because the network is constantly updated information, the user to obtain the latest information needs to be with the same key words repeated query.
